Dear Planning Participant:

This letter accompanies the Record of Decision (ROD), Final Environmental Impact Statement (Final EIS) and Amended Land and Resource Management Plan (Forest Plan) which respond to a decision issued by the 9th Circuit Court of Appeals.

In August 2005, the U.S. Court of Appeals for the Ninth Circuit issued a decision in *Natural Resources Defense Council, et al., v. United States Forest Service, et al., 421 F.3d 797 (9th Cir. 2005)* that found deficiencies in the process used to develop the 1997 Forest Plan revision. Specifically, the Court found inadequacies related to timber demand, the range of alternatives considered relative to timber demand and potential effects on roadless areas, and cumulative effects from activities conducted on non-National Forest System lands. The Court ordered additional analysis and the development of an environmental impact statement (EIS) to correct these deficiencies. The documents being released today address all of the deficiencies identified by the Court, as well as a number of needs identified by the 5 Year Review of the Forest Plan.

The Tongass' extensive collaboration with many new and existing partners has played a very important role in the development of this Amendment and will continue to be an integral part of the forest management in the future. The Forest worked with State and Federal agencies, Tribal Governments, SE Alaska Communities, organizations and individuals to develop this Amended Forest Plan. One of the most significant partnerships is with the State of Alaska, designated as a Cooperating Agency for this analysis. Governor Sarah Palin and Forest Service Chief Abigail R. Kimbell signed a Preamble to the ROD, which sets the vision for sustainability of the Tongass and for Southeast Alaska's communities in a coordinated effort to improve and promote natural resource management.

Approximately 84,500 comments were received on the Draft EIS. These comments were used to refine the analysis and shape the decision. A summary of comments and Forest Service responses can be found in Appendix H of the Final EIS.

One important element of the Plan that many have been anticipating is the amount of timber the Forest can offer for timber sales over the life of this Plan. The Allowable Sales Quantity, or ASQ, in the Amendment remains unchanged from the 1997 Plan of approximately 267 million board feet a year over the next 10 years. The total suitable land base the Plan outlines for timber harvest is comparable to the 1997 Plan at about 773,000 acres.

What is a significant change in the Amended Plan is how the Forest will plan and offer timber sales. The ROD introduces a new strategy, referred to as the Timber Sale Adaptive Management Strategy, which limits the lands available for timber harvest to that necessary to support demonstrated levels of demand. While the majority of higher value roadless areas are not available for timber harvest, this strategy will ensure those areas that are available are not impacted until timber demand rises.

The new Timber Sale Adaptive Management Strategy will be implemented in three phases, based upon performance. Under Phase 1 timber harvests will be restricted to roaded and mostly lower value inventoried roadless areas (areas in close proximity to existing roads) until the level of timber harvest reaches 100 million board feet a year for two consecutive years.

Phase 2 restricts harvest to Phase 1 lands and additional moderate value inventoried roadless areas (areas farther from existing roads with multiple-use value for recreation, fish and wildlife use) until the level of timber harvest reaches 150 million board feet a year for two consecutive years. Finally, Phase 3 of the Strategy applies, and includes the remaining suitable land base. A map of these phases is included on the CD and on the website at *www.fs.fed.us/r10/tongass/*.

The ROD, Final EIS and Amended Forest Plan will be published in the Federal Register in early to mid February. The Amended Forest Plan can be implemented 30 days from that date. Publication in the Federal Register also begins a 90 day appeal period. See the ROD for more information.

All of these documents as well as more information about the amendment process can be found at *www.fs.fed.us/r10/tongass/*. Please contact Lee Kramer, the Project Manager at 907-789-6246 for more information.

Sincerely,

FORREST COLE

Tongass Land and Resource Management Plan

Final Environmental Impact Statement

Plan Amendment

Record of Decision

A Shared Vision
For the Tongass National Forest

For untold millennia, people in Southeast Alaska have been tied to the land and the seas, and lived within their embrace. Still today, 73,000 people live in intimate contact with this marvelous environment. Hundreds of thousands more visit every year, hoping to sense in some small way what Alaskans experience daily. Much of what local residents experience - and what visitors sense - comes directly from that wondrous treasure, the Tongass National Forest.

The Record of Decision you have before you is a complex legal document, filled with technical details and references to the laws, policies, regulations, and court cases that make up the fabric of modern resource management. That's pretty obvious. What is not so obvious is the new partnership between the State of Alaska and the U.S. Forest Service that is foundational to this decision. The previous Chief of the Forest Service and State of Alaska administration opened a new door to collaborative relations almost two years ago, which has expanded to include many vital, dynamic, and diverse interests as this decision was formed. We are working together in productive ways that were literally unthinkable just a few years ago. Today, we renew our commitment to work together and support a new collaborative model of management.

It is vital that you see this shared vision for this Forest, and that you understand the thinking and hope that this decision can bring more stability to its management. Above all, we want to see sustainability, of the Tongass and of Southeast Alaska's communities, in perpetuity. The Tongass National Forest is one of the few places left where people still live connected to the land and make their living surrounded by unparalleled abundance and wildness. We want to see it stay that way.

We believe that the Tongass National Forest is a unique public treasure entrusted to our care. Through this decision, we are conserving its intrinsic value for future generations. The Tongass will continue to be a rich, healthy forest of wild places with abundant wildlife and fish. Most of the Forest will be protected as Wilderness and as remote backcountry, and will remain one of the world's most important intact ecosystems.

The lands of the Forest must also provide the foundation of the economic well-being of the communities embedded within it. A healthy commercial fishing industry depends on the Forest's abundant fish habitat. Mining and timber have long provided jobs for the people of Southeast, and through responsible resource management they can continue to do so. And the remote and isolated communities within the Forest must have opportunities to connect to each other, for both transportation and energy.

We also want to help stabilize the economic and social viability of communities in Southeast Alaska. Without sufficient timber resources, a crucial element of these communities is in danger of disappearing. Because people in this country, as well as the rest of the world, require a lot of timber products, the wood product industry offers one of the best ways to retain that viability. Helping businesses succeed is important to both the health of the forest and its people. We are committed to them, because the people who live in Southeast Alaska are crucial to the health of the landscape in which they live.

At the same time, the Tongass is part of a global community, influenced by the effects of international markets and trends. Preserving special places requires engaging local people and responding to their interests and values. Alaska's forests are increasingly valued for the global environmental services they provide, such as plentiful clean air and water, abundant fish and wildlife, carbon sequestration, biodiversity, and opportunities to enjoy outdoor recreation.

The new State-Federal cooperation is key to the successful implementation of the Plan. We must strengthen our coordination of wildlife conservation monitoring and timber sale operations, while recognizing that full implementation will require adequate funding. With this decision, we also renew our commitment to work together to ensure subsistence protections guaranteed under the Alaska National Interest Lands Conservation Act. We hope, and believe, that our efforts to work together will strike a chord with your own interest in the Tongass National Forest and Southeast Alaska.

Our vision of the future says this new plan will meet the needs of the people of Southeast Alaska while protecting the wild places we all love. The framework is here, and with our newfound sense of State-Federal cooperation, and the addition of an adaptive management strategy, we believe we can also work together on how best to make the plan work for all of us.

That is our vision – we hope you will join with us in making it a reality.

Record of Decision

Introduction

This document is a public Record of Decision (ROD) that documents my decision to approve the 2008 Amendment to the Tongass Land and Resource Management Plan (Forest Plan), and the rationale for making that decision. The amended Forest Plan is contained in the document titled *Land and Resource Management Plan – Tongass National Forest*, dated January 2008, and is based on Alternative 6 in the *Tongass Land and Resource Management Plan Amendment Final Environmental Impact Statement* (Final EIS), with four modifications as described in this document. The map of record for the amended Forest Plan is labeled "Tongass National Forest, Land Use Designations, January 2008."

Under the National Forest Management Act (NFMA), the Secretary of Agriculture is required to "develop, maintain, and, as appropriate, revise land and resource management plans [forest plans] for units of the National Forest System." 16 U.S.C. § 1604(a). Forest plans are expected to be reviewed every 5 years, and revised every 15 years. 16 U.S.C. § 1604(f)(5)(A); 36 CFR § 219.10(g). Pursuant to 16 U.S.C. § 1604(g), the Secretary of Agriculture promulgated regulations at 36 CFR Part 219[1] establishing procedures for the development, amendment, and revision of forest plans. Because this amendment essentially completes the process of revising the Tongass Forest Plan that was initiated in 1987, the Forest Plan will not need to be revised again for 10 to 15 years, unless changed conditions require it sooner.

Forest planning on the Tongass National Forest has long been a complex and contentious undertaking. This history is described in detail in Chapter 1 of the Final EIS, so I will offer only a brief summary of it here. In 1979, the Tongass National Forest was the first to complete a forest plan under NFMA. As required by NFMA's implementing regulations, the Forest Service completed a 5-year review of the Forest Plan in 1984, which led to an amendment of the Forest Plan that was completed in 1986. The agency began work to revise the Forest Plan in 1987. The Tongass Timber Reform Act became law in November 1990, which resulted in a second amendment to the Plan in 1991. The Revised Forest Plan was approved in 1997, and was appealed by several parties. The Under Secretary of Agriculture affirmed the 1997 decision, but also issued a new ROD that modified the 1997 Plan, mainly to prohibit timber harvest and road construction in 18 "areas of special interest." As a result of subsequent litigation, the 1999 ROD was vacated, and the Forest Service was directed to prepare a Supplemental EIS to determine whether additional wilderness areas should be recommended. That Supplemental EIS was completed in 2003; based on that analysis, I recommended no additional wilderness.

The validity of the 1997 Forest Plan was challenged, and that litigation eventually resulted in a decision by the U.S. Court of Appeals for the Ninth Circuit in *Natural Resources Defense Council vs. U.S. Forest Service* (421 F.3d 797) in August 2005. The Forest Service had erroneously nearly doubled the market demand for timber from the Tongass that was projected by Forest Service economists. The court found that this error influenced the selection of Alternative 11 in the 1997 ROD. The court also found inadequacies in the 1997 EIS, including the following:

- The EIS did not provide decision makers and the public with an accurate assessment of information relevant to evaluating the Tongass Plan; had the accurate market demand forecast and related potential employment and earnings information been used, an alternative may have been selected with less environmental impact and in less environmentally sensitive areas.

[1] The Forest Service promulgated new planning regulations in 2000, and again in 2005. In accordance with the transition provisions of the 2005 regulations, the 2008 Tongass Forest Plan Amendment was prepared pursuant to the pre-2000 regulations. All citations in this ROD to regulations in Part 219 refer to the pre-2000 regulations.

- The Forest Service had not considered alternatives that set the Allowable Sale Quantity (the maximum amount of timber allowed to be cut) equal to the correct demand scenarios.
- Each of the alternatives considered allocated some currently roadless areas to the Land Use Designations (LUDs) that allow development; the EIS omitted an alternative that allocated less undeveloped land to the development LUDs.
- The EIS did not fully consider the cumulative effects of disproportionate high-volume logging on non-federal land because the EIS did not include: (1) a catalog of past projects; (2) a discussion of how those projects (and differences between the projects) have harmed the environment; (3) a discussion of the connection between individual non-federal high-volume harvests and the prior environmental harm from those harvests; and (4) an assessment of the potential impacts of reasonably foreseeable continued "highgrading" in the future.
- A cumulative effects analysis in a programmatic EIS is necessary for the Forest Service and the public to make a rational evaluation of the proposed action balancing the competing goals of timber harvest, environmental preservation, and recreational use in the Tongass.

The 2008 Tongass Forest Plan Amendment and the associated EIS have been prepared in response to the Ninth Circuit court's decision. The Amendment also responds to the 5-Year Review of the Plan completed in early 2005, which recommended several updates to the Plan.

Forest plans are programmatic in nature; they do not, by themselves, authorize activities such as timber harvest or road construction that affect the environment. Rather, when an individual project (such as a timber sale) is proposed, the Forest Service undertakes a site-specific analysis of its likely environmental effects and renders a formal decision regarding it. *See Inland Empire Public Lands Council v. U.S. Forest Service*, 88 F.3d 754 (9th Cir. 1996); *Sierra Club v. Robertson*, 28 F.3d 753, 758 (8th Cir. 1994). Thus, forest plans do not have environmental effects. *Ohio Forestry Ass'n v. Sierra Club,* 523 U.S. 726, 729 (1998). However, the planning regulations governing the 2008 Tongass Forest Plan Amendment require the preparation of Environmental Impact Statements for forest plans. 36 CFR § 219.10(b).

My objectives for the 2008 Forest Plan Amendment and the associated EIS have consistently been to correct the deficiencies identified by the Ninth Circuit and bring the Plan up to date, while balancing the competing goals cited by the court. My overall intent has always been to ensure that the Tongass National Forest continues to be managed in a sustainable manner. NFMA requires forest plans to "provide for multiple use and sustained yield of the products and services" obtained from the National Forest System. 16 U.S.C. § 1604(e)(1). Sustained yield of products and services is defined as "the achievement and maintenance in perpetuity of a high-level annual or regular periodic output of the various renewable resources of the national forests without impairment of the productivity of the land." 16 U.S.C. § 531(b). I also recognize the State of Alaska's authority and responsibility to ensure sustainable management of fish and wildlife on all lands in Alaska. Multiple use management is a deceptively simple term that describes the enormously complicated task of striking a balance among the many competing uses to which land can be put, including outdoor recreation, range, timber, watershed, wildlife, fish, and wilderness. The additional goal of sustained yield requires the Forest Service to control consumptive uses of natural resources of the National Forest System to ensure a high level of valuable uses in the future.

For reasons that will be explained throughout this ROD, I conclude the amended Forest Plan meets all of these very challenging requirements.

The Decision

The decision I am making today is to approve the amended Forest Plan, which is based on Alternative 6 as described in the Final EIS, with the four modifications that are described in this ROD. The components of this decision are listed below. These decision components are fully supported by the environmental analysis documented in the Final EIS, as required by law and regulation. The details of these decision components may be found in the Forest Plan chapters or appendices noted.

I have made my decision after careful consideration of the public comments on the Draft EIS for the 2008 Tongass Land and Resource Management Plan Amendment, which was prepared pursuant to the National Environmental Policy Act (NEPA). I have also reviewed the Final EIS and the amended Forest Plan. All site-specific projects will be subject to additional environmental analysis, which will tier to the Final EIS for the amended Forest Plan.

The amendment I am approving modifies four of the six components of the Forest Plan that are required by law and regulations governing forest planning. In addition to the required components, I am also approving a Timber Sale Program Adaptive Management Strategy, which is an additional step in implementing adaptive management and correcting the deficiencies identified by the Ninth Circuit court. As part of this decision, I also direct the Forest Supervisor to strengthen the cooperative efforts with the State of Alaska on implementation and monitoring, including efforts to improve timber sale economics, by developing cost-sharing and other agreements with the State of Alaska. This direction is described in detail in the section of this ROD dealing with implementation.

Decision Components Required by NFMA

Goals and Objectives

Multiple-use goals and objectives for the Tongass are described in Chapter 2 of the Plan. These goals and objectives guide the overall management for the Forest, establish the desired conditions for implementing the Plan, and satisfy the requirements of 36 CFR 219.11(b). Achievement of these goals and objectives will ensure the sustainability of the Tongass National Forest, and the ecological, social, and economic values derived from the Forest. These goals and objectives describe the mosaic of land and resource conditions desired for the forest in the future. Full attainment of these goals and objectives can be influenced by a number of factors, such as congressional budget allocations, changed circumstances or new information relative to land management.

The amended Plan includes several changes to the goals and objectives adopted in 1997. A new goal has been added to maintain viable plant communities and populations and a mixture of habitats capable of supporting the full range of naturally occurring flora. It also includes a new goal to consult with Tribes to protect and maintain sacred sites across the Forest. New objectives are included for each of these goals. A new objective was added to reduce the introduction, spread, and impact of invasive species. Two new objectives related to timber management were also added. One addresses “economic timber” in the timber sale program; the other deals with flexibility and stability in the sale program. In addition to the new goals and objectives, several others were modified. More emphasis was given to ecosystem services values. The goal for karst was re-written to focus on maintaining natural processes and productivity while allowing other land uses as appropriate. Several goals and objectives were updated to clarify management intent.

Management Prescriptions

Chapters 3 and 4 of the amended Plan set forth the management prescriptions and forest-wide standards and guidelines that describe how land managers will operate on the Tongass. These chapters provide the expectations and limits on how and where activities will be conducted. The management prescriptions in Chapter 3 include 16 Land Use Designations, each with its own goals and objectives, and specific standards and guidelines designed to ensure achievement of them. Management prescriptions for the Wilderness and National Monument Wilderness LUDs have been combined to reduce duplication, while retaining separate goals and objectives for National Monument Wilderness. Several other management prescriptions have been changed slightly to update and clarify them. Many of the forest-wide standards and guidelines (Chapter 4) were also edited to update their terminology, clarify them, and improve the consistency of application. New standards and guidelines were developed to address invasive species and plants. Another new standard was added that requires old-growth forest structure (i.e., live trees, dead trees, and clumps of trees) to be retained after timber harvest in areas that have had considerable past harvest, as a replacement for standards in the 1997 Forest Plan related to goshawk foraging and marten habitat.

The 19 LUDs are commonly organized into four groups with similar management direction and environmental effects. The first two groups are commonly referred to as "non-development LUDs, and the latter two groups as "development LUDs." The main changes from the 1997 Forest Plan in the allocation of land on the Tongass to the various LUDs include:

1. Updated acreage figures for all LUDs as a result of refinements to the geographic information system and better inventory information regarding scenery.
2. The addition of approximately 90,000 acres[2] to the network of small Old-Growth Habitat reserves, as discussed in the section of this ROD dealing with protecting wildlife habitat and biodiversity. Some of these additional acres were previously allocated to development LUDs, others to non-development LUDs.
3. Expansion of Geologic Special Interest Areas to protect nearly 47,000 acres of newly identified karst lands that are most vulnerable to disturbance from development.
4. Reallocation of about 97,000 acres on the Juneau Icefield from Remote Recreation to Semi-remote Recreation, which would allow minor enclaves to be established above the snow accumulation zone.
5. Reallocation of about 43,000 acres on Chichagof Island at the head of Tenakee Inlet from Timber Production, Modified Landscape, and Old-Growth Habitat to Semi-remote Recreation to address the high sensitivity of this area to development and timber economics.
6. Reallocation of about 18,000 acres on Kupreanof Island east of Kake from Timber Production to Semi-remote Recreation to address public concerns and timber economics.
7. Reallocation of development LUDs near Bostwick Inlet on Gravina Island to Semi-remote Recreation in response to public concerns, as described in greater detail in the section of this ROD dealing with minimizing effects on roadless areas. These are changes that I am making through this decision to Alternative 6 as displayed in the Final EIS.
8. Allocations among the development LUDs were adjusted to reflect improved inventory data regarding scenery. These are changes that I am making through this decision to Alternative 6 as displayed in the Final EIS.
9. An expansion of the Minerals LUD overlay by approximately 80,000 acres (from 170,514 to 249,570 acres) to include portions of the Hyder area and areas on Prince of Wales Island associated with the Niblack, Ruby Tuesday, and Khayyam minerals prospects.

The amended Forest Plan's allocation of all National Forest System lands on the Tongass to the various LUDs is shown in Table 1 below.

Activities consistent with management prescriptions are guided by the application of standards and guidelines, which govern resource management activities and are key to successful implementation of the Forest Plan. Some of these standards and guidelines apply to all lands, others to specific management prescriptions. These standards and guidelines take precedence over annual targets or projected outputs; no project or program will be funded for which the applicable standards and guidelines cannot be carried out.

The primary LUDs that allow timber management, Timber Production, Modified Landscape, and Scenic Viewshed, total approximately 3.4 million acres, or 20 percent of the Tongass National Forest. Three of these LUDs, Timber Production, Modified Landscape, and Scenic Viewshed, account for all of the scheduled timber harvest under the Forest Plan. Scenic and Recreational River LUDs also allow timber management if the adjacent LUD allows timber harvest and the scenery guidelines are met; however, very little harvest has occurred in these LUDs over the last 10 years. Accordingly, I expect little if any timber harvest in these LUDs over the next 10 to 15 years.

[2] This includes approximately 50,000 acres added by previous amendments to the 1997 Forest Plan.

Table 1
Land Use Designations for the Amended Forest Plan

Land Use Designation	Total Acres Allocated to Each LUD[1]	Total Acres Allocated to Each LUD without Overlays[2]
Wilderness LUD Group		
Wilderness	2,637,292	2,637,292
Wilderness National Monument	3,111,792	3,111,792
Nonwilderness National Monument	166,942	166,942
Total for Wilderness LUD Group		**5,916,026**
Natural Setting LUD Group		
LUD II	721,002	721,002
Remote Recreation	2,033,665	2,033,665
Semi-Remote Recreation[3]	3,023,152	3,023,152
Old-Growth Habitat	1,221,173	1,221,173
Enacted Municipal Watershed	45,226	45,226
Research Natural Area	58,788	26,093
Special Interest Area	342,137	221,176
Wild River	192,463	62,799
Scenic River	27,133	27,133
Recreational River	27,387	27,387
Total for Natural Setting LUD Group		**7,408,806**
Development LUD Group		
Experimental Forest[4]	31,405	31,405
Scenic Viewshed	307,402	307,402
Modified Landscape	728,679	728,679
Timber Production	2,381,486	2,381,486
Total for Development LUD Group		**3,448,972**
Overlay LUD Group[5]		
Minerals	249,570	0
Transportation and Utility Systems	--	0
TOTAL NATIONAL FOREST SYSTEM LAND		**16,773,804**

1 This column includes the total acreage allocated to each LUD. However, in some cases, more than one LUD can be applied to the same area (such as a Special Interest Area within Wilderness); therefore, totaling the acres of this column will exceed the total National Forest acreage.

2 This column counts each acre of the Tongass only once. It includes the total areas allocated to each LUD, except for five LUDs that sometimes overlay other LUDs. The Research Natural Area, Special Interest Area, and Wild River LUDs sometimes overlay Wilderness, Wilderness National Monument, or LUD II; when this occurs the acreage is included under these other LUDs (so as not to double count). Also, the Minerals and Transportation and Utility System LUDs always function as overlays and do not have acreage in this column.

3 The acreage figure for this LUD includes 6,544 acres currently allocated to Experimental Forest, but proposed to be converted to Semi-Remote Recreation.

4 The acreage figure for this LUD includes 20,853 acres currently allocated to Scenic Viewshed, but proposed to be converted to Experimental Forest.

5 The two LUDs in this group are always overlay LUDs. Areas allocated to these LUDs are managed according to the underlying LUD until such time that mineral or transportation/utility development is approved, if at all. The Minerals overlay LUD has an area (249,570 acres) associated with it; no acreages are calculated for the Transportation and Utility System LUD because it is defined as a series of corridors of undefined width and imprecise locations.

Land Suitable for Timber Production

The amended Forest Plan also updates the classification of lands suitable for timber production and determines where on those lands timber harvesting could be allowed, in accordance with NFMA regulations, 36 CFR 219.14(a), and Section 102 of the Tongass Timber Reform Act (TTRA). Appendix A of the Forest Plan details the criteria and process used to determine the forest lands suitable for timber production. These are the lands capable of producing commercial volumes of timber on a sustained-yield basis, and are not in areas legislatively withdrawn from timber harvest. They are the only lands where regularly scheduled timber harvest may occur.

This process uses a computer model that takes into consideration a number of characteristics of land across the entire Tongass National Forest. Changes were made to reflect updated geographic information system data; the results of a new logging systems and transportation analysis; and a new, lower estimate of the Model Implementation Reduction Factor.[3] As a result of these updates, the total estimated suitable land area decreased from 781,000 acres under the 1997 Forest Plan (as amended) to 773,000 under the 2008 Amendment. In addition, new modeling was conducted to identify the maximum acreage of lands from the suitable land base that would need to be scheduled for harvest over the next 100 years or so, in order to produce timber each decade at the maximum level permitted under the Allowable Sale Quantity. As a result of these updates, the total amount of scheduled suitable land decreased from 687,000 acres under the 1997 Forest Plan (as amended) to 663,000 acres under the 2008 Amendment.

Commercial timber sales can occur on lands that are not identified as suitable for timber production, but only if needed to accomplish other management objectives. Examples include commercial thinning of dense young-growth forest stands to improve wildlife habitat, and salvage sales of trees damaged or killed by insects or disease, or blown down by wind storms. Such sales are infrequent on the Tongass, are not part of the scheduled timber program, and thus do not count toward the Allowable Sale Quantity.

Allowable Sale Quantity

The Allowable Sale Quantity (ASQ) is the maximum amount of timber that can be sold in the first decade following this decision. It has not been changed; the ASQ for timber for the amended Forest Plan is established at 2.67 billion board feet per decade, which is equivalent to an annual average of 267 million board feet (MMBF). This is an upper decadal limit on the amount of timber that may be offered for sale from suitable timberland on the Tongass National Forest as part of the regularly scheduled timber sale program. As mentioned above, the ASQ is unchanged from that established for the 1997 Forest Plan. However, the timber program will be implemented in three phases under the Timber Sale Program Adaptive Management Strategy, as explained in detail later in this section and in other sections of this ROD.

Annual offering levels depend on several factors. For the Tongass National Forest to offer timber sales at levels near the maximum allowed under the amended Plan, Congress would need to consistently appropriate sufficient funding, the Forest Service would need to increase the number of timber sales prepared and offered, and the timber industry would need to take advantage of additional marketing opportunities, make new capital investments, purchase sales offered, and harvest timber at rates higher than current levels.

As was true under the 1997 Plan, the ASQ consists of two separate Non-Interchangeable Components (NICs) called NIC I, which is 2.38 billion board feet of timber per decade, and NIC II, which is 0.29 billion board feet per decade. The NIC I component includes land that can be harvested with normal logging systems and is typically more economic to harvest. The NIC II component includes land that has high logging costs due to isolation or special equipment

[3] The Model Implementation Reduction Factor reduces the amount of land identified by the model as suitable for timber production to account for unforeseen factors that arise during implementation of the Plan. The Factor was reduced from approximately 32 percent in the 1997 Forest Plan to approximately 23 percent in the amended Forest Plan, as a result of updates to the geographic information system and other data.

requirements. These NIC components are estimates that do not reflect all of the factors that may influence actual sale levels. They are designed to prevent the disproportionate harvest of the most economical portions of the Forest over the long term. Thus, the separate limits on each component are binding on a decadal basis. The components are non-interchangeable because lower sale levels in one component may not be compensated for by higher sale levels in the other. About 89 percent of the ASQ comes from NIC I land and about 11 percent comes from NIC II.

Monitoring and Evaluation

The monitoring plan, required by NFMA regulations, 36 CFR section 219.12 (k), is contained in Chapter 6 of the amended Forest Plan. It represents an essential quality control mechanism and facilitates learning from Plan implementation. The monitoring plan provides for three types of monitoring: (1) implementation monitoring to determine if the standards and guidelines are being followed; (2) effectiveness monitoring to determine if standards and guidelines are achieving the desired results; and (3) validation monitoring to determine if the underlying assumptions are valid.

Monitoring and evaluation play a central role in adaptive management. Some monitoring and evaluation activities are conducted to ensure appropriate implementation of standards and guidelines. Other activities are conducted to deal with uncertainties regarding effects of land management activities. This includes gathering additional information to reduce these uncertainties by determining whether the effects of various standards and guidelines are consistent with predictions, and also to validate key assumptions underlying various standards and guidelines and projected outcomes of management. Information gained through monitoring and evaluation will be used to adjust management direction in the future where warranted. Accordingly, monitoring and evaluation will be a high priority under the amended Forest Plan. The monitoring plan contained in the amended Forest Plan specifies the questions to be answered through monitoring. Several modifications were made to refine the critical monitoring questions, including more emphasis relative to emerging climate change issues. Information on sampling methods and other detailed information about how the questions might be answered has been removed, because these provisions tend to be frequently updated to respond to new science and information. Details of the monitoring program such as data gathering protocols will continue to be developed in consultation with the State of Alaska and other interested Federal agencies.

The Forest Service will conduct an evaluation of the Forest Plan in 5 years, as provided by the NFMA planning regulations (36 CFR 219.10(g)). That review will include an evaluation of the Plan's old-growth conservation strategy, which is designed to conserve biodiversity and prevent the need to list species under the Endangered Species Act. The evaluation will be conducted in collaboration with appropriate Federal and State agencies. Any needed changes in the Plan's direction will be incorporated through the amendment or revision process, just as this amendment was prepared, in part, in response to information obtained under the monitoring and evaluation program established under the 1997 Forest Plan.

Recommendations on Special Management Areas

As described in Chapter 1 of the Final EIS, the purpose and need of the 2008 Forest Plan Amendment is to respond to the 2005 decision by the U.S. Court of Appeals for the Ninth Circuit, and to update the Plan in response to the 5-year evaluation completed in 2005. Accordingly, changes to wilderness areas, wild and scenic rivers, and research natural areas are outside the scope of the Amendment. During this amendment process, however, I reviewed the decision I made in 2003 not to recommend that any new wilderness areas be designated, or any changes to existing wilderness areas be made. I made that decision because I found no compelling need for additional wilderness on the Tongass at that time. I believe the 2003 decision should remain in effect. Consequently, this decision does not include any additional wilderness recommendations. Potential wilderness recommendations can be considered again as part of the next revision.

Similarly, I am making no changes to the recommendations made by the Regional Forester in 1997 that segments of over 30 rivers be included in the National Wild and Scenic Rivers System.[4] These recommendations require action by the Chief of the Forest Service and the Secretary of Agriculture before being considered by the President for transmittal to Congress. No changes are being made to the network of research natural areas currently designated on the Tongass.

Although the scope of this Amendment did not include proposals to add new wilderness areas, wild and scenic rivers, or research natural areas, or to expand existing units of these systems, there is one change to a special management area that I am recommending. In response to a request from the Pacific Northwest Research Station, I join the Director of the Station in recommending to the Chief of the Forest Service that the designation of Young Bay on Admiralty Island as an experimental forest be terminated and that a new experimental forest in the Cowee Creek and Davies Creek watersheds on the mainland north of Juneau be established. Admiralty Island is not accessible by road, which is needed to fully achieve the objectives of an experimental forest. The proposed new experimental forest is accessible from the Juneau road system. Unless and until the Chief approves these recommendations, Young Bay will be managed as an experimental forest, and the Cowee Creek-Davies Creek area will be managed under the Scenic Viewshed and Old-Growth Habitat LUDs. Upon approval by the Chief and execution of any necessary public land orders, Young Bay will be managed under the Semi-Remote Recreation LUD, which includes the termination of the existing mineral withdrawal, and the Cowee Creek-Davies Creek area will be managed as an experimental forest. While only the Chief can make the decision on these recommendations, the potential environmental effects of that decision—other than issues related to mineral withdrawals--are described in the Final EIS for this Forest Plan Amendment. Upon approval by the Chief, we would make a technical correction to the Plan to reflect that approval.[5]

Changes Adopted in this ROD to Alternative 6

As mentioned briefly above, I have decided to make four changes to Alternative 6 as displayed in the Final EIS. The following changes have been incorporated into the amended Forest Plan:

- Development LUDs in the vicinity of Bostwick Inlet on Gravina Island have been changed to Semi-remote Recreation.
- Allocations of development LUDs have been changed (e.g., from Scenic Viewshed to Modified Landscape) to reflect updated scenery inventory information.
- The standard and guideline included in Alternative 6 that would allow timber harvest within goshawk nest buffers if nests are unoccupied for two years has been changed. The amended Forest Plan will continue to protect all known nests; only buffers around "probable nests" may be subject to timber harvest, and only if two years of monitoring indicates no evidence that goshawks are present or actually nesting. This change is explained further in the section of this ROD dealing with protecting fish and wildlife habitat and biodiversity.
- The standard and guideline in Alternative 6 that requires project-level analysis of ways to reduce excessive human-caused wolf mortality has been changed to require such analyses to evaluate the effects of human access to the project area via all roads, not just roads open to vehicular traffic as included in Alternative 6. This change is explained further in the section of this ROD dealing with protecting fish and wildlife habitat and biodiversity.

[4] The 1997 ROD recommended that portions of 32 rivers, lakes, and streams be added to the National Wild and Scenic Rivers System. In 1998, the Acting Forest Supervisor determined that the 1997 recommendation for Niblack Lakes and Streams was based on incorrect information related to the area's productivity of anadromous fish, and adopted a non-significant amendment rescinding the recommendation that the Niblack Lakes and Streams system be designated as a component of the National Wild and Scenic Rivers System. I conclude the remaining 31 recommendations should remain in effect.

[5] If the Forest Service chooses to pursue withdrawing the new Experimental Forest from the mining and mineral leasing laws, additional NEPA analysis and public involvement will occur before making that decision.

Timber Sale Program Adaptive Management Strategy

I am keenly aware that my decision to approve an amendment that retains the same ASQ as in the 1997 Forest Plan will be controversial. Some people requested a higher ASQ be adopted, to ensure an opportunity for the timber sector to expand into a fully integrated and competitive industry.[6] Others asked for a lower level, to prevent unnecessary development of roadless areas perceived by some as most environmentally sensitive. Multiple use management requires that such competing demands be balanced in a sustainable manner. I believe my decision accomplishes this difficult task. A detailed explanation for my decision, including why I believe it responds to these concerns and how it remedies the inadequacies identified by the court, is provided below in the "Rationale for the Decision" section of this ROD. To further balance the competing demands and respond to requests for additional protection of roadless areas, I am also approving the Timber Sale Program Adaptive Management Strategy. As mentioned above, the decision to approve this Strategy is in addition to the decision components that are required by NFMA and its implementing regulations.

Under the Timber Sale Program Adaptive Management Strategy, actual operation of the timber sale program will be implemented in three phases, as determined by actual timber harvest levels. In Phase 1, the timber program will be restricted to a portion of the suitable land base that excludes moderate and higher value roadless areas[7]. The map of the Strategy is included on the CD of the Final EIS, and is also available on the internet at *www.fs.fed.us/r10/tongass/*. This Phase 1 portion includes approximately 537,000 suitable acres, or 69 percent of the total suitable land base. Should the actual level of timber harvest reach 100 MMBF for two consecutive fiscal years, the Tongass could then plan for timber projects in the Phase 2 portion of the approved suitable land base, resulting in a program that operates on 680,000 acres of suitable lands, including some moderate value roadless areas. Should timber harvest reach 150 MMBF for two consecutive fiscal years, the Tongass could then plan for timber projects in Phase 3, which includes the entire suitable land base. A more detailed explanation of the Timber Sale Program Adaptive Management Strategy and my reasons for adopting it are provided in the Implementation section of this ROD.

As mentioned previously, the Timber Sale Program Adaptive Management Strategy is an additional step being taken in response to concerns that an overestimate of timber demand will lead to timber harvest in areas perceived by many as more environmentally sensitive--such as higher value roadless areas--that would not have to be developed if the Plan were based on a lower estimate of timber demand. It is very difficult to estimate long-term timber demand with a high degree of precision and confidence when local, regional, and global market conditions are constantly changing. Therefore, the Timber Sale Program Adaptive Management Strategy—in conjunction with the amended Forest Plan--addresses the Ninth Circuit court's finding that, if the 1997 Tongass Forest Plan Revision EIS had provided decision makers and the public with the correct market demand forecast, an alternative may have been selected with less environmental impact and in less environmentally sensitive areas.

The Forest Service has a statutory obligation to seek to meet market demand for timber from the Tongass National Forest, both the annual demand and demand for each planning cycle of 10-15 years, subject to other applicable law and to the extent consistent with providing for the multiple use and sustained yield of all renewable forest resources.[8] I am confident that the amended Forest Plan continues to meet these other resource goals, including recreation and the maintenance of biological diversity, as described in the Rationale for the Decision section of this ROD. I am also concerned that the current timber industry in Southeast Alaska is not sustainable at the current harvest levels, or with uncertain future timber harvest levels. Accordingly, it is prudent to keep options open so that

---

[6] For the purposes of this ROD, an integrated timber industry is one with local milling and processing facilities for each kind of log that comes from harvest operations on the Tongass National Forest. Competition is created between processors for similar supply needs.

[7] The term "roadless area" is a generic term that is sometimes used to refer to all areas without roads. For the purpose of this ROD, it is used to refer to inventoried roadless areas, as discussed in detail in the section of this ROD titled "Rationale for the Decision."

[8] See the market demand portion of the Rationale for the Decision section for a detailed discussion of this issue.

the timber industry in Southeast Alaska can evolve in response to long-term market developments, including a significant expansion if demand for timber rises substantially in the future. As long as other competing demands are being met, it is important to avoid constraining the lands available for timber harvest so much that it is impossible for the timber industry to expand in response to future market developments. At the same time, however, it is not necessary to schedule timber harvest in higher value roadless areas, unless timber harvest levels rise sufficiently to warrant such an expansion into these sensitive areas.

Adaptive management principles suggest we respond to uncertainty by adopting a flexible management system that balances the short- and long-term social, economic, and environmental risks and adjusts promptly if conditions change. The Timber Sale Program Adaptive Management Strategy, along with all the other conservation measures in the amended Forest Plan, is just such a system. Together, the amended Forest Plan and Adaptive Management Strategy do not guarantee an expansion of the timber industry; nor do they prohibit development in all roadless areas. Rather, they keep options open for expansion of the industry (within the ASQ approved in this Plan), while protecting areas that are perceived as more environmentally sensitive as much as possible for as long as possible. My confidence in this Strategy is further strengthened by the expected increase in young-growth[9] management over the next few planning cycles; and the increasing public interest in this conversion, which will ultimately reduce the need for old-growth timber resources and the associated need for development in roadless areas.

This is discussed in greater detail in the section of this ROD describing the rationale for the decision.

Alternatives Considered

Numerous EISs have been published as part of the development of the 1997 Forest Plan; together these EISs have considered dozens of alternatives. A Draft EIS was published in 1990, a Supplement to the Draft EIS in 1991, a Revised Supplement to the Draft EIS in 1996, a Final EIS in 1997, a Draft Supplemental EIS (addressing only whether additional wilderness should be proposed) in 2002, and a Final Supplemental EIS regarding additional wilderness in 2003. As displayed in Table 2 below, these EISs considered in detail 39 different alternatives, many of which appeared in more than one EIS. Further information on the evolution of the alternatives considered is provided below in the discussion of alternatives not analyzed in detail. In addition, Chapter 2 of the Final EIS for this Amendment provides a detailed description of the evolution of the alternatives considered.

[9] The term “young growth” refers to areas where trees have been removed by timber harvest, fire, insects, disease, or windstorms, and then grown back.

Table 2
Statistics for 39 Tongass Forest Plan Alternatives Considered in Detail; 1990 – 2003

Alternative No. and Source	ASQ [1] (MMBF annual)	Suitable lands (Acres X 1,000)	Non-Development LUDs (Acres X 1,000)	Development LUDs (Acres X 1,000)
1 1997	0	0	16,700	200
1 1996	0	74	16,700	200
6 2003	92	344	15,700	1,200

7 1996	689	2,044	9,100	7,800

Notes:
Sources: 1990 Draft EIS, 1991 Supplement to the Draft EIS, 1996 Revised Supplement to the Draft EIS, 1997 Final EIS, and 2003 Supplemental EIS)
[1] All ASQ figures in this table are shown as total volume, including net sawlog plus utility. The 1990 Draft EIS and the 1991 Supplement to the Draft EIS display ASQ figures as net sawlog only. Therefore, figures in this table for alternatives displayed in those documents do not match the figures originally published.

Development of Alternatives Included in the Draft EIS

As noted in the Final EIS, one of the fundamental objectives that guided the development of alternatives for the Draft EIS on the 2008 Forest Plan Amendment was to exclude roadless areas from the development LUDs (the Land Use Designations that allow timber harvest and road construction) as much as possible in each alternative. Because the Tongass has so little developed land, this is possible only at very low levels of timber harvest. Therefore, planners assessed each inventoried roadless area using the Wilderness Attribute Rating System, the only nationally established methodology for evaluating the quality of roadless areas, as well as their fish and wildlife values, recreation and subsistence values, and other multiple use values. They also gave extra consideration to 18 areas of special interest identified by the Under Secretary of Agriculture in the ROD he issued in 1999, and to 23 areas that would have been designated as wilderness under a bill passed by the House of Representatives in 1989. The development of alternatives was guided by these considerations and, at each stage, as an alternative with a higher level of timber harvest was being developed, the minimum amount of roadless acres were added to the development LUDs, starting with lower value roadless areas. In this way, at each level of timber harvest associated with each of the alternatives, development is allowed in roadless areas only to the extent necessary to achieve the multiple use objectives of the alternative, including timber production; each alternative excludes the higher value roadless areas from the development LUDs as much as possible. Alternatives were modified in response to public comments received on the Draft EIS, as explained in the section of this document dealing with minimizing effects on roadless areas.

In deciding which of the previously evaluated alternatives to analyze in this EIS, consideration was also given to alternatives that had been reviewed by the wildlife risk assessment panels that were formed during the development of the 1997 Forest Plan. This objective was accomplished for four of the seven alternatives. Given that the risk assessment panels showed a high correlation between development acres and the risk they assigned to an alternative, coupled with the fact that the harvest levels of all alternatives considered in detail in the 2008 Final EIS were bracketed by alternatives evaluated by the risk assessment panels, viability risk levels could be readily assigned to all alternatives. See Appendix D of the Final EIS for details on the application of the risk assessment panels to the alternatives considered in the 2008 Final EIS.

Alternatives Considered in Detail, Including the No-Action Alternative

Alternative 1

Compared to the 1997 Forest Plan, Alternative 1 would give much greater emphasis to maintaining roadless areas, associated fish and wildlife values, and recreation, tourism, and subsistence opportunities in undeveloped areas. In response to public comments on the Draft EIS, this alternative was modified to preclude timber harvest in all roadless areas. Development LUDs on Kuiu Island, Baranof Island, much of Chichagof Island, the Yakutat area, and essentially all of the mainland also were changed to non-development LUDs in response to comments on the Draft EIS. Consequently, no scheduled timber harvest or road construction would be allowed on these areas under Alternative 1. The standards and guidelines of the 1997 Forest Plan dealing with foraging habitat for the northern goshawk and with high value habitat for the American marten would be replaced with a new legacy standard and guideline. A total of 839,000 acres of the Tongass would be in development LUDs, 15.9 million acres would be in non-development LUDs, and 144,000 acres, including 86,000 acres of old growth, would be in the suitable land base. This alternative would have an average annual ASQ of 49 MMBF.

Alternative 2

Compared to the 1997 Forest Plan, Alternative 2 would give additional emphasis to maintaining roadless areas, associated fish and wildlife values, and recreation, tourism, and subsistence opportunities in undeveloped areas, but not as much as Alternative 1. Timber harvest would be allowed in areas where roads have already been constructed, and in roadless areas with lower wilderness attribute ratings (primarily those adjacent to developed areas). The vast majority of current roadless areas would remain in a natural condition. The goshawk foraging habitat and high value marten habitat standards and guidelines of the 1997 Forest Plan would be replaced with a new legacy standard and guideline. A total of 1.9 million acres of the Tongass would be in development

LUDs, 14.8 million acres would be in non-development LUDs, and 394,000 acres, including 215,000 acres of old growth, would be in the suitable land base. This alternative would have an average annual ASQ of 151 MMBF, and closely matches the recommendations provided by The Nature Conservancy for the protection of intact watersheds.

Alternative 3

Compared to the 1997 Forest Plan, Alternative 3 would give some additional emphasis to maintaining roadless areas, associated fish and wildlife values, and recreation, tourism, and subsistence opportunities in undeveloped areas. Timber harvest would be allowed in areas where roads have already been constructed, and in many roadless areas within the suitable land base, which excludes higher value roadless areas identified in previous planning or congressional wilderness proposals. The vast majority of current roadless areas Forest wide would remain in a natural condition. The goshawk foraging habitat and high value marten habitat standards and guidelines of the 1997 Forest Plan would be replaced with a new legacy standard and guideline. A total of 2.8 million acres of the Tongass would be in development LUDs, 14 million acres would be in non-development LUDs, and 514,000 acres, including 313,000 acres of old growth, would be in the suitable land base. This alternative would have an average annual ASQ of 204 MMBF.

Alternative 4

Compared to the 1997 Forest Plan, Alternative 4 would give greater emphasis to timber production and associated economic stability of Southeast Alaska communities. Timber harvest would be allowed in a more extensive area than under the 1997 Forest Plan. While the majority of current roadless areas would remain in a natural condition, roadless areas outside of wilderness that contain substantial productive old growth would be subject to timber harvest and road construction. Alternative 4 would use a conservation strategy with a smaller number of reserves than the 1997 Forest Plan strategy; the old-growth reserve system would be applied within four biogeographic provinces (North Central Prince of Wales Island, Kupreanof/Mitkof Islands, Dall Island, and Northeast Chichagof Island) plus several individual reserves outside of these provinces. In addition, a minimum of 33 percent of productive forest land would be retained in an old-growth condition in each Value Comparison Unit.[10] The goshawk foraging habitat, high value marten habitat standard and guideline and the proposed legacy standard and guideline would not be included in the Forest Plan under Alternative 4. The goshawk nesting standard and guideline would also not be included. A total of 4.7 million acres of the Tongass would be in development LUDs, 12.0 million acres would be in non-development LUDs, and 892,000 acres, including 656,000 acres of old growth, would be in the suitable land base. This alternative would have an average annual ASQ of 312 MMBF in the first decade (and 360 MMBF in subsequent decades).

Alternative 5

This is the No Action alternative. It represents a continuation of the 1997 Forest Plan, as previously amended, and would result in a mix of National Forest uses and activities. Timber harvest would be allowed in an area more extensive than under Alternative 3, but less extensive than under Alternative 4. The vast majority of current roadless areas Forest wide would remain in a natural condition. A total of 3.6 million acres of the Tongass would be in development LUDs, 13.2 million acres would be in non-development LUDs, and 687,000[11] acres, including 463,000 acres of old growth, would be in the suitable land base. This alternative would have an average annual ASQ of 267 MMBF.

[10] Value Comparison Units are approximately 950 distinct geographic areas delineated on the Tongass to provide a common set of areas for resource inventories and analysis. They generally follow watershed boundaries.

[11] This figure does not match that provided in the 1997 Final EIS due to updated inventory information, land adjustments, and previous Forest Plan amendments.

Alternative 6

This is the alternative identified as the Proposed Action in the Draft EIS. It is very similar to Alternative 5 (No Action) in terms of LUD allocations; however, it includes refinements to the boundaries of small old-growth reserves, new Geologic Special Interest Areas, a new Experimental Forest proposal, the conversion of a large area of Remote Recreation LUD north of Juneau to Semi-Remote Recreation, the conversion of development LUD areas on Chichagof and Kupreanof Islands to Semi-remote Recreation, and other minor LUD refinements. Timber harvest would be allowed in an area more extensive than under Alternative 3, but slightly less extensive than under Alternative 5. The vast majority of current roadless areas Forest wide would remain in a natural condition. The goshawk foraging habitat and high value marten habitat standards and guidelines of the 1997 Forest Plan would be replaced with a new legacy standard and guideline. A total of 3.5 million acres of the Tongass would be in development LUDs, 13.3 million acres would be in non-development LUDs, and 663,000 acres, including 445,000 acres of old growth, would be in the suitable land base. This alternative would have an average annual ASQ of 267 MMBF.

Alternative 7

Compared to the 1997 Forest Plan, Alternative 7 would give much greater emphasis to timber management. Timber harvest would be allowed in a more extensive area than under the 1997 Forest Plan. While the majority of current roadless areas would remain in a natural condition, most roadless areas outside of wilderness that contain substantial productive old growth would be subject to timber harvest and road construction. The Beach and Estuary Fringe buffer would be reduced from 1,000 to 500 feet and buffers on Class III streams would not be required. The Old-Growth Habitat LUD and its management prescription would not be used. The standards and guidelines for goshawk foraging habitat, high value marten habitat, and legacy would not be included in the Forest Plan under Alternative 7. The goshawk nesting standard and guideline would also not be included. A total of 5.0 million acres of the Tongass would be in development LUDs, 11.7 million acres would be in non-development LUDs, and 1,070,000 acres, including 807,000 acres of old growth, would be in the suitable land base. This alternative would have an average annual ASQ of 421 MMBF. Alternative 7 was incorporated in the NEPA analysis at the request of the Southeast Conference.

Alternatives Considered but not Analyzed in Detail

As mentioned above, the Forest Plan revision process started in 1987 and resulted in the development of numerous environmental documents, which cumulatively described dozens of alternatives. Each of these alternatives was considered for detailed study and comparison in the Draft EIS for the 2008 Forest Plan Amendment, in their original form or in a modified form. Altogether, 49 alternatives were considered for detailed study prior to the selection of the EIS alternatives; 39 based on past alternatives (which formed the basis for Alternatives 1, 3, 4, 5, and 7), and 10 new ones (which formed the basis for Alternatives 2 and 6). These alternatives were considered in light of the key issues and the purpose and need. They ranged in ASQ, the maximum amount of timber that can be sold on an average annual basis, from 0 to almost 700 MMBF per year. Development LUD acres in these alternatives ranged from a few hundred acres to almost 8 million acres, and suitable forest lands ranged from 0 to over 2 million acres. Chapter 2 of the Final EIS contains a more thorough discussion of the alternatives not analyzed in detail.

The Environmentally Preferable Alternative

The Council on Environmental Quality (CEQ) regulations for implementing NEPA require that the Record of Decision specify “the alternative or alternatives which were considered to be environmentally preferable” (40 CFR 1505.2(b)). This alternative has generally been interpreted to be the alternative that will promote the national environmental policy as expressed in NEPA’s Section 101 (CEQ’s “Forty Most-Asked Questions”, 46 *Federal Register*, 18026, March 23, 1981). Ordinarily, this means the alternative that causes the least adverse effect to the biological and physical environment. Alternative 1 of the Final EIS is the environmentally preferable alternative.

Rationale for the Decision

Summary

I reached my decision to select Alternative 6 with the modifications described in this ROD, and to approve the Tongass Timber Sale Program Adaptive Management Strategy, after a comprehensive review and careful consideration of the relevant ecological, economic, and social potential effects of the Final EIS alternatives. During my consideration of the Final EIS and in reaching my decision, I have been guided by a wide variety of factors. Among the most important of these are how best to respond to problems identified by the Ninth Circuit Court of Appeals in their 2005 decision, many of which were identified as key issues in the EIS, and other considerations including those related to national policy.

The following explanation of why I selected Alternative 6 from among the seven alternatives analyzed in the Final EIS addresses each of these factors in great detail. Another key factor in my decision is compliance of the Forest Plan with applicable laws, regulations, and executive orders, as described in detail in a separate section of this ROD. Here, I want to provide a short summary of my thinking.

When I contemplate all of the information about legal requirements, effects analyses, risk assessments, and all the other factors relevant to this decision, it still comes down to sustainability of the multiple uses and resources of the Forest: How can we best balance the competing demands on the Tongass National Forest, when there is uncertainty about those demands and the effects of trying to meet them? Specifically, how can we best balance:

- Potential risks to fish and wildlife from building roads and harvesting timber with the risks of local mills shutting down if their need for that timber cannot be met?
- Potential adverse effects on recreational use of the Tongass with the level of timber harvest allowed?
- The advantages of an integrated timber industry with the potential resource effects of allowing a sufficient level of timber harvest to enable new processing facilities to be built?

Finally, how do we ensure that higher value roadless areas perceived as most environmentally sensitive are being protected from development as much as possible at whatever rate timber is harvested and roads are constructed?

The most logical approach to me is to deal with fish and wildlife issues first, then with recreation issues, timber demand, issues related to an integrated industry, and protecting roadless areas in that order. This does not reflect any relative value of the issues or the resources, only what I see as the logical order of dealing with them.

Fish and Wildlife Habitat and Biodiversity. The management of habitat to maintain the long-term viability of all Tongass fish and wildlife species as well as to sustain subsistence, recreational, and commercial uses of these resources is a key factor in my decision. This decision relies heavily on the sound scientific foundation developed in the 1997 Tongass Forest Plan, especially the fish and riparian standards and guidelines and the comprehensive wildlife conservation strategy prepared through an interagency collaborative process. All key components of this conservation strategy have been incorporated in the amended Forest Plan. The conservation strategy ensures the maintenance of viable populations of all vertebrate species on the Tongass by means of a comprehensive approach based on principles of conservation biology. Implementation of this strategy also recognizes the State of Alaska's responsibility to provide for sustainable fish and wildlife resources and the human uses of these resources. The old-growth habitat strategy included in the amended Forest Plan is fully responsive to our obligations to manage habitat to maintain viable populations within a multiple-use context. This strategy has been developed through careful analysis and integration of the best scientific information available on this subject, and will minimize fragmentation of old-growth habitat on the Forest.

The strategy includes two major components. First is the system of large, medium and small old-growth reserves well distributed throughout the Tongass. This system of reserves is made up of areas allocated to the Old-Growth Habitat LUD, plus lands in all the rest of the non-development LUDs, which essentially maintain the integrity of the old-growth system. This component provides adequate habitat for old-growth dependent or associated species, and provide for connectivity between reserves in order to prevent genetic isolation of populations. The reserve system protects 72 percent of the existing productive old-growth habitat on the Tongass. The second major element of the wildlife conservation strategy is a series of standards and guidelines applicable to those portions of the Tongass open to consideration for potential timber harvest. The standards and guidelines regulate how development will occur on those areas open to potential development. Standards and guidelines incorporate a species-by-species approach that addresses issues that are more localized or not accounted for in the broader, ecosystem context approach that was incorporated into the old-growth reserve system. These standards and guidelines protect an additional 19 percent of the existing productive old-growth habitat on the Tongass. Between the reserve system and the standards and guidelines that apply to the development LUDs, the amended Forest Plan will protect 91 percent of the existing productive old-growth habitat on the Tongass.

The purpose of both components of the strategy is to ensure the viability of old-growth dependent or associated species. The 1997 ROD concluded that the strategy provided assurance, subject to an acceptable level of risk inherent in projecting management effects, that even if timber were harvested and roads were constructed consistently for a period of 100 years at the Plan’s maximum allowable levels, viable populations of all vertebrate species on the Tongass would remain at the end of that period. Largely because of scientific uncertainty, the conservation strategy (and any other conservation strategy) involves some degree of risk. Therefore, the 1997 Plan did not represent a “no risk” conservation strategy. It represented a balance of wildlife conservation measures that considered the best available scientific information and reflected an acceptable level of risk for continued species viability, based on conservative assumptions.

In the spring of 2006, experts in the field of conservation biology and Tongass-related species came together with agency representatives in a workshop to assess new information from conservation science and species research; discuss the implications of that new information for the underlying assumptions of the conservation strategy; and determine whether there was a need to modify or replace the existing strategy. On the basis of the information presented at the workshop, the Forest Service concluded that the conservation strategy remains valid and appropriate for the long-term management of the Tongass National Forest. Many ideas were discussed at the workshop. The Forest Service considered all of these ideas, and incorporated some of them into the analysis associated with this Forest Plan Amendment. The status and outcome of all topics considered during the workshop can be found in the document titled: Interagency Conservation Strategy Review: An Assessment of New Information Since 1997.

As described in greater detail in a later section of this ROD, the Final EIS describes the potential effects of the Forest Plan on the probability of sustaining viable populations of wildlife species on the Tongass. As I review that information, I am struck by several key points. First, there are no terrestrial species on the Tongass listed as threatened or endangered under the Endangered Species Act. Second, the analysis in the Final EIS indicates no species will trend toward listing with implementation of the Forest Plan. The conclusion of that analysis is that the amended Forest Plan will provide an amount and distribution of habitat adequate to maintain viable populations of vertebrate species in the planning area and will maintain the diversity of plant and animal communities. In addition, the amended Forest Plan has a high likelihood of sustaining populations Forest-wide for the continued subsistence, recreational, and commercial uses of fish and wildlife species.

Recreation and Tourism. As discussed in detail in the section below on this subject, the analysis in the Final EIS suggests that relatively minor changes in the mix of recreational opportunity settings may occur over the next 150 years under the amended Forest Plan. Changes to settings are related to projected levels of future development. The magnitude and rate of these changes will be influenced by the level at which timber harvest and associated road construction occurs. Even if such development occurs at the maximum level allowed under the amended Forest Plan, some of these changes—an increase in opportunities for road-based recreation—will be desirable to some people, and undesirable to others. This may result in users being displaced to other areas where the setting and use patterns are more in line with their expectations and needs. The Tongass National Forest is overwhelmingly pristine and unroaded, and will remain that way under the amended Forest Plan. Therefore, I conclude there will be no significant reduction in recreation and tourism opportunities as a result from implementation of the Forest Plan over the next 10 to 15 years, and some opportunities may be enhanced.

Timber Demand. Based on my confidence in the assurance of maintaining fish and wildlife viability and recreational opportunities, the next question is how to deal with uncertainty related to timber demand. Once again, I recognize that I am making a decision for 10 to 15 years, while considering potential effects over a longer time horizon. In this case, however, if the decision is inadequate to meet the needs of the timber industry over the next 10-15 years, the industry simply will not be around for corrections to be made during the next Plan revision. State and private forest lands in Southeast Alaska are not able to provide an adequate supply to meet the minimum level needed for current mills to remain in operation. There are also questions about whether the industry will expand in the future if a supply of timber is available. Such an expansion would allow the industry to become more efficient and enhance its competitive position, improving its sustainability. While approving a Plan with an ASQ high enough to allow such an expansion will not make it happen; adopting an ASQ that meets only current needs will certainly prohibit it. Therefore, once viability concerns are met, it makes sense to approve a Plan with an ASQ high enough to allow current mills to increase their production to efficient operating levels and provide some room for new processing facilities, which will help maintain a vibrant and diverse economy in Southeast Alaska. As explained in detail in the section of this ROD dealing with market demand, the amended Forest Plan accomplishes that result.

Need for an Integrated Forest Products Industry in Southeast Alaska. Beyond the question of what the market demand for timber is likely to be over the next 10 to 15 years, I also considered what supply would be needed to provide an opportunity to reestablish an integrated forest products industry in Southeast Alaska. As explained in detail in the section of this ROD on this subject, the existing timber industry in the region has been at a competitive disadvantage in world markets since the closure of the pulp mills in the 1990s. Reestablishing an integrated industry, including processing facilities for all types of material harvested on the Tongass, would require a reliable supply of economic timber from the Forest. Providing an opportunity for additional processing facilities to be established is an important step to ensuring the economic sustainability of the industry. An integrated industry would make commercial thinning more economically feasible, allowing more restoration work in watersheds where past practices have led to degraded ecological conditions. If local processing facilities can be established for utility[12] logs, they would no longer be left in the woods. Accordingly, establishment of an integrated industry would further the goals of ecological, as well as economic, sustainability. I selected Alternative 6, which has an ASQ substantially above recent harvest levels, in part to provide such opportunities—and to ensure they are not foreclosed.

Minimizing Effects on Roadless Areas. Having met requirements dealing with viability, recreation, and timber demand, and having provided opportunities for the development of an integrated timber industry, we turn finally to minimizing effects on roadless areas. Paramount among these concerns is how to ensure that development occurs first on the lower value roadless areas, since the ASQ of the Forest Plan is considerably above recent harvest levels, while protecting the higher value roadless areas and those perceived as more environmentally sensitive as much as possible. The amended Forest Plan and Adaptive Management Strategy limit timber harvest to lower value roadless areas unless harvest levels rise sufficiently to warrant allowing timber harvest in moderate value and higher value roadless areas.

[12] Utility logs are those with so much rot or otherwise of such poor quality that they cannot be sawn into lumber. They are relatively common in old-growth forests, comprising approximately 15 percent of the volume of timber cut on the Tongass. For safety and logistical reasons, such trees within a timber harvest unit must be purchased and cut down, even though the purchaser may have no use for them. In recent years, they have often been cut down and left in the woods.

Conclusion. For the reasons described above, I conclude that my decision to approve the amended Forest Plan and the Timber Sale Program Adaptive Management Strategy meets all legal requirements, and best balances the many competing demands on the Tongass National Forest. The conservation strategy included in the amended Forest Plan ensures that healthy populations of wildlife will remain across the Tongass; the Adaptive Management Strategy protects higher value roadless areas; the LUD allocations and standards and guidelines minimize effects on recreation and tourism; and the ASQ associated with the LUD allocations and management direction provides opportunities for the timber industry to expand sufficiently to become more integrated and competitive in world markets. In short, my decision ensures the sustainability of the multiple uses of the Tongass and of the outstanding natural resources of the Forest that we all treasure.

I recognize that there is enormous value in maintaining the Tongass for the suite of ecosystem services it provides to the world. More detail on the difficulty of monetizing these values is discussed below, yet there is no doubt they exist, and I have given them full consideration. People come to Alaska to catch salmon; to see bears; to see bears catching salmon; to enjoy the tranquility of an old-growth forest – forests with and without roads. People come here to boat on pristine coastal waters; to see whales and other marine mammals. Hunters come here to pursue deer and bears on these mountainous islands; some of them by car, and others preferring a more rugged and isolated experience in our many roadless areas. I believe all of these visitors, like many Alaska residents, treasure the abundant populations of fish and wildlife species dependent on the Tongass and its old-growth forests. This nature-based tourism is a valuable industry for Southeast Alaska. These rainforests are also critical to another important Southeast Alaska industry, commercial fishing. Well protected streams and their clean, cool waters are critical for large and lucrative salmon runs, on which both humans and animals thrive year after year. Trees are another valuable, renewable resource the Tongass has to offer. Trees are valuable in many forms--standing on the ground; downed, dead and decomposing on the forest floor; and sitting on a log truck headed for a local saw mill. The latter is a form that can provide for an important and sustainable industry that contributes to a diverse economy, without detracting from the other values I recognize as important to the public. Simply put, on a forest as vast as the Tongass, which is blessed with an abundance of these renewable resources, I believe it is important to maintain opportunities for all uses to occur, and at a scale which is both beneficial to local communities and respectful of broader national interests. Managed in a sustainable and environmentally sensitive manner, I believe the Forest Service can provide the raw materials of the Tongass to support a healthy wood products industry, a growing tourism industry, and a robust fishing industry in perpetuity. I am confident that the amended Forest Plan I am approving today can achieve that result.

The remaining portions of this section explain in detail the rationale for my decision, starting with an elaboration of the considerations described above, including how they relate to problems identified by the Ninth Circuit Court of Appeals in its 2005 opinion, and to the key issues identified in the Final EIS.

Protecting Fish and Wildlife Habitat and Biodiversity

Background

NFMA requires the Secretary of Agriculture to specify "guidelines for land management plans developed to achieve the goals of the Program which … provide for diversity of plant and animal communities based on the suitability and capability of the specific land area in order to meet overall multiple-use objectives…" (16 U.S.C. 1604(g)(3)(B)). In accord with this diversity provision, the Secretary promulgated a regulation that provides in part: "Fish and wildlife habitat shall be managed to maintain viable populations of existing native and desired non-native vertebrate species in the planning area. For planning purposes, a viable population shall be regarded as one which has the estimated numbers and distribution of reproductive individuals to insure its continued existence is well distributed in the planning area." (36 CFR 219.19.)

The scientific community and courts recognize that NFMA does not create a concrete, precise standard for diversity. The Committee of Scientists that provided scientific advice to the Forest Service on the drafting of NFMA regulations stated that "it is impossible to write specific regulations to ‘provide for’ diversity” and “there remains a great deal of room for honest debate on the translation of policy into management planning requirements and into management programs” (44 Fed. Reg. 26,600-01 & 26,608).

In this planning context, absolute certainty is not possible. This has led to a planning process which involves risk projections regarding the distribution of species over the next 100 years. Numerous factors, which vary according to the characteristics of the ecosystem examined, are considered in evaluating risk. Some common factors include the life history of the species, the current amount and distribution of habitat, the amount and distribution of species’ ranges within the planning area, and other reasonably foreseeable protective measures. In as biologically diverse and expansive an area as the Tongass, much of this type of information is evolving. Moreover, even absent any human-induced effects, the likelihood that habitat will continue to support species’ persistence can vary among species. For example, the continued persistence of local rare endemic species whose entire range may comprise only a few acres is intrinsically insecure. Thus, compliance with the regulation is a matter of assessing risk, which is not subject to precise numerical interpretation and cannot be fixed at any one single threshold. Because long-term risk varies among species, even when using the best scientific projections available, it is also necessary to follow-up with rigorous monitoring of select key species and their habitats to ensure that populations remain healthy, particularly in areas of the Forest with higher levels of timber harvest. These monitoring expectations and commitments are described in Chapter 6 of the Forest Plan, titled “Monitoring and Evaluation.”

In determining compliance with the NFMA fish and wildlife resource regulation, I have considered existing and reasonably foreseeable conservation measures. In addition to the Plan’s land allocations (which protect 78 percent of the Forest in non-development LUDs) and standards and guidelines, other possible measures include activities undertaken pursuant to internal policy directives (e.g., the Forest Service’s sensitive species program) and steps taken during project planning. The one issue that remains uncertain and could, in the future, alter assumptions made in the Final EIS is the effects of climate change. Consequently, it is important for the Tongass to stay abreast of the evolving scientific information related to the effects of climate change and how this may affect fish and wildlife populations. However, the state of current knowledge and the uncertainty about the specific effects of climate change leads me to conclude that the best course of action today is continued management of the Tongass for resiliency in the face of uncertain but anticipated change. This will be done primarily through the maintenance of the conservation strategy, coupled with a robust monitoring plan that will allow for management intervention if and when effects of climate change are more certain. I have determined that the combination of providing for an amount and distribution of habitat adequate to maintain viable populations of vertebrate species in the planning area and increased emphasis on monitoring climate-related changes is a reasonable solution.

Summary

The Final EIS describes the potential effects of the Forest Plan on the probability of sustaining viable populations of wildlife species on the Tongass. The conclusion of that analysis is that the Forest Plan will provide an amount and distribution of habitat adequate to maintain viable populations of vertebrate species in the planning area and will maintain the diversity of plant and animal communities. That conclusion is based in large part on viability risk assessments prepared by panels of experts for the 1997 Plan. Based on these assessments and all the other analyses, the 1997 Forest Plan EIS estimated that there was a moderate to very high probability of maintaining sufficient habitat to maintain viable populations of wildlife species on the Tongass under the 1997 Plan. The risks associated with the 1997 Plan were related to the scientific uncertainty of projecting long-term effects of management actions. I believe those probability estimates are very conservative for the following reasons:

- The viability risk assessments assumed continuous timber harvest at the maximum level allowed under the Plan (the ASQ level of 267 MMBF annually) for 100 consecutive years, with no change in applicable standards and guidelines during that entire period. In essence, they did not assess the risks associated with a 10- to 15-year decision, but with a 100-year decision.

- Risks that viable populations would not be maintained are generally low, would only arise several decades into the future, and then only if timber were continuously harvested at or near the maximum ASQ level.
- Timber has not been harvested on the Tongass at or near the maximum ASQ level throughout a single planning cycle, let alone several. The first Tongass Forest Plan was adopted in 1979, and was in effect through May of 1997. It had an annual average ASQ of 549 MMBF of total volume.[13] Total volume harvested from 1980 through 1996 averaged 327 MMBF annually, only 60 percent of the ASQ. Since adoption of the 1997 Forest Plan, total volume harvested has averaged 84 MMBF annually, only 32 percent of the annual average ASQ of 267 MMBF. I do not expect timber to be harvested at a continuous rate of 267 MMBF over the next planning cycle of 15 years, let alone 100 years.
- If timber harvest rises to 267 MMBF annually over the next 10-15 years, or even beyond that level in the future, the planning process ensures that any issues that may emerge regarding sustaining viable populations of wildlife species on the Tongass will be addressed. Plans must be revisited through a public process every 10-15 years. Each time, the latest scientific information is examined to determine what changes may be needed. The Forest Service and other State and Federal agencies will continue to monitor implementation of the Forest Plan and its results. If a viability-related problem were to develop, it would not go unnoticed—it would be addressed.
- Standards currently in effect are far more protective than those of 20 or 40 years ago. It is highly likely that standards will continue to become more effective over the next several decades through adaptive management as the scientific understanding of how to minimize the adverse environmental effects of human activities continues to improve.

I want to be clear that I believe the analysis displayed in the Final EIS of potential effects on wildlife is valid. Land management decisions must consider very long-term potential effects to ensure they are sustainable. To estimate such potential effects, assumptions must be made about what management direction will apply in the future. It would be impossible to predict what changes in policy might be made over the next 100 years. Yet I am not making a 100-year decision today; I am making a 10- to 15-year decision. Experience tells us that standards do become more effective over time, and timber is not harvested at maximum allowable levels for long, if ever. While the members of the viability assessment panels may have concluded there is no scientific basis upon which to make different assumptions, the ones made are very unlikely to occur, and render the viability analyses something close to a "worst case scenario." Consequently, while I am mindful of the fact that there are some long-term viability risks associated with implementing the Forest Plan over the next 10 to 15 years, I believe those risks are very small. For example, Chapter 3 of the Final EIS indicates that 92 percent of the productive old-growth forest that ever existed on the Tongass remains today. Over the next 15 years, even if timber is harvested at the maximum rate allowed under the amended Forest Plan over that entire period, less than 3 additional percent would be harvested and 89 percent of the original productive old-growth forest (97 percent of the existing productive old growth forest) would remain. I believe the risks associated with this level of activity are completely acceptable. Moreover, I am confident that any problems that may surface in the future will be addressed through the public planning process. Accordingly, I am as certain as I can be that this decision ensures the maintenance of viable wildlife populations as required by NFMA. A more detailed discussion of issues related to viability is provided below.

The Old-Growth Habitat Reserves

The amended Forest Plan strengthens the protection of old-growth habitat in two ways. First, it improves the network of small old-growth reserves through work completed by an interagency team.

[13] The ASQ of the 1979 Plan was expressed as 450 MMBF, which counted sawlog only. The 549 MMBF figure includes utility volume as well, as displayed in the 1997 Final EIS for the Tongass Forest Plan Revision.

Biologists from the State of Alaska, U.S. Fish and Wildlife Service (FWS), and the Forest Service reviewed nearly 300 small old-growth reserves identified in the 1997 Forest Plan and recommended reconfigurations for many of them. My decision acts on those recommendations. The amended Forest Plan includes an updated set of old-growth reserves that is approximately 90,000 acres larger than the old-growth reserve system contained in the 1997 Plan. Some 13 old-growth reserves require more analysis at the project level before any changes are made, as described in Appendix K of the Forest Plan. My decision enhances the network of small old-growth reserves by incorporating habitat protections identified through the interagency review; for example, the need to protect narrow habitat corridors known as “pinch points” that connect larger patches of habitat. At the same time, the changes in the small old-growth reserves will reduce operational conflicts, such as problems encountered when gaining access to suitable timber lands.

The second enhancement in old-growth protection is a substantial increase in the amount of land allocated to other non-development LUDs. By increasing these allocations by 69,000 acres, the amended Forest Plan is expected to be more beneficial with respect to wildlife habitat than the 1997 Plan.

The Tongass now has an estimated 4,951,000 acres of productive old-growth forest. Changes in this amendment will increase the portion of productive old growth in non-development LUDs from 71 percent under the 1997 Forest Plan to 72 percent. Another 19 percent of productive old-growth forest will be protected by the standards and guidelines that apply to the development LUDs. Overall, the amended Forest Plan protects 91 percent of the existing productive old growth on the Tongass National Forest. Not all of that is of equal value in terms of wildlife habitat quality. Many believe that high-volume old growth is higher quality habitat. An even smaller subset of the old-growth forest—the large-tree old growth--is also often perceived as higher quality wildlife habitat. The large-tree category is characterized by stands that have a coarse canopy texture and typically contain the largest trees and the highest timber volumes. The amended Forest Plan protects over 90 percent of the existing high-volume old growth on the Tongass National Forest, and 89 percent of the existing large-tree old growth. Appendix D of the Final EIS discusses these considerations in more detail, as does the Biodiversity section of Chapter 3 of the Final EIS. Based on my review of these analyses, I am confident that the amended Forest Plan ensures that high quality wildlife habitat will remain abundant on the Tongass National Forest.

Standards and Guidelines That Apply in Development LUDs

Another component of the old-growth conservation strategy, management standards and guidelines, applies to lands not contained within the system of old-growth reserves. Rather, these standards and guidelines apply to those lands with LUD allocations that provide for the scheduled harvest of timber—the development LUDs. While these LUDs comprise 21 percent of the Forest, only about 4 percent of the Forest would actually be scheduled for potential harvest over the next 100+ years. Within the development LUDs, some standards and guidelines aim to ensure protection of important old-growth habitats and connectivity. Key examples are the 1,000-foot buffers along beaches and estuaries and the streamside buffers protecting riparian zones. Other standards and guidelines preclude or significantly limit logging in areas with high-hazard soils, steep slopes, karst terrain, visually sensitive travel routes and use areas, and timber stands technically not feasible to harvest. All of these key standards and guidelines are maintained in this decision because they protect important resources and serve vital connectivity functions within the network of old-growth reserves.

Some changes to wildlife standards and guidelines are being adopted in this decision. The purpose is to maintain the high level of protections afforded in the 1997 Plan, while also allowing additional flexibility during on-the-ground implementation. The minor changes serve to clarify standards and guidelines that were being either misinterpreted or inconsistently applied. The adoption of a Forest-wide legacy standard and guideline as a replacement of the 1997 goshawk foraging and marten habitat standards and guidelines is a major change. The new standard and guideline applies in watersheds where the level of past or anticipated timber harvest is high. By requiring the retention of forest structural components such as patches of large trees, down logs, and snags (dead trees) after timber harvest in more biogeographic provinces, the legacy standard and guideline will provide beneficial effects to more species in more areas across the Tongass than the standards and guidelines of the 1997 Forest Plan.

The Queen Charlotte Goshawk

Conservation organizations petitioned the FWS to list the Queen Charlotte goshawk subspecies of the northern goshawk (*Accipiter gentilis laingi)* as endangered in May 1994. The FWS has repeatedly determined that listing is not warranted, largely on the basis of protections provided by the conservation strategy in the 1997 Tongass Forest Plan. The most recent status update and finding was published in November 2007. The FWS found that the best available information does not support the listing of the Alaska population segment as threatened or endangered at this time. However, the FWS also concluded that Vancouver Island is a significant portion of the Queen Charlotte goshawk's range and that listing the subspecies in British Columbia is warranted.

I am mindful that the FWS made its non-warranted determination for Alaska goshawks largely on the basis of protections in the 1997 Forest Plan. This is reflected in my decision to maintain the key components of the conservation strategy in the amended Forest Plan, so as to continue providing a high level of protection for the goshawk. However, the decision does include three changes that affect goshawk habitat. These are: 1) adjustments to the network of small old-growth reserves and increases in other non-development LUDs, as described in the preceding section; 2) changes to the goshawk nest buffer standard and guideline; and (3) adoption of a new Forest-wide legacy standard and guideline that replaces the goshawk foraging standard and guideline contained in the 1997 Plan.

The 1997 Tongass Forest Plan EIS estimated that Alternative 11, as displayed in that EIS, had a high likelihood of maintaining viable populations of goshawks well-distributed across the Tongass, even if timber were harvested and roads constructed for 100 years at the maximum levels allowed by Alternative 11. This estimate did not take into account several goshawk-specific measures that were added in the final decision after the assessment was conducted. These measures were added to Alternative 11--the Selected Alternative--to further reduce risk to the goshawk, in recognition that the species had been considered for listing under the Endangered Species Act. One such measure was prescribed for goshawk habitat on Prince of Wales Island, where productive old-growth has been fragmented by past management actions such at timber harvest and road construction. This goshawk foraging standard and guideline, applicable within the most-fragmented watersheds on Prince of Wales Island, sought to retain habitat structure for goshawk nesting, foraging, and dispersal between old-growth reserves.

The Final EIS for the 2008 Forest Plan Amendment considered the cumulative changes in the conservation strategy in describing the potential effects on goshawks. Changes that enhance the old-growth reserve system, as described in the previous section, figure importantly in this analysis. These enhancements include a net addition of acres to the old-growth reserve network; improvements in the configuration of small reserves recommended by the interagency team; and the additions to other non-development LUDs that are part of this decision. The enhanced reserve network in the amended Forest Plan, coupled with the 1,000-foot wide beach buffers and other features that provide habitat connectivity, should provide a similar if not stronger foundation for maintaining goshawk populations across the Tongass. Overall, at least 91 percent of the existing productive old growth (83 percent of all old growth that ever existed on the Tongass) would remain on the Tongass, even if timber were harvested at the maximum level allowed by the Forest Plan for 100 consecutive years. In addition, over this same time period, a significant acreage of young growth that is protected from future harvest (equal to about 5 percent of the original amount of old growth) will be reaching mature forest stages and will also have value as goshawk habitat. For these reasons, I conclude that an abundant supply of habitat suitable for goshawk nesting and foraging will persist across the Tongass.

Because the protection of known goshawk nests is paramount, I am modifying Alternative 6 as displayed in the Final EIS to ensure that confirmed nests will continue to be protected by a 100-acre buffer of old-growth habitat, as required by the 1997 Forest Plan. The amended Forest Plan does, however, make a change to the 1997 Plan to allow some management flexibility in stands where goshawks have been observed but no direct or indirect evidence of a confirmed nest is documented.

Such stands are defined as “probable nest stands.” Under the amended Forest Plan, activities may be allowed within the 100 acres surrounding probable nest stands, but only if—after 2 years of monitoring—there is no additional evidence of goshawk use. A requirement to survey for goshawks prior to timber harvest remains in effect, as does a commitment to monitoring. Therefore, I anticipate that management situations enabled by this change would be rare, and that goshawk populations would not be affected.

As another change relating to goshawks, I am adopting a Forest-wide legacy standard and guideline in lieu of the goshawk foraging standard and guideline contained in the 1997 Plan. This change stems from the desire for a more comprehensive (versus single-species) approach to retaining old-growth structural components in areas of timber harvest, and for more consistency in application across the Forest. The legacy standard and guideline applies to higher risk VCUs across the Forest, whereas the 1997 Plan’s goshawk foraging standard applied just to higher risk VCUs on Prince of Wales Island. Therefore, the beneficial effects of retaining old-growth structure, for example in retaining connectivity and habitat conditions for prey, will apply to goshawks throughout their range on the Tongass National Forest. My decision to adopt this change also responds to operational and economic considerations associated with timber harvest, which is another important objective in this plan. This standard and guideline will be monitored to ensure it functions as expected.

The benefits to wildlife of leaving large trees, snags, and downed logs after timber harvest is well documented in the scientific literature, including studies on goshawk and their primary prey species. However, there is no scientific basis to guide managers as to how much structural material should be retained, and in what configurations, to specifically benefit goshawks and their prey in southeast Alaska. I am basing my decision on research that suggests that retaining clumps of trees is more beneficial than retaining single trees. Clumps receive more use by wildlife and are more windfirm than scattered residual trees. Applying the legacy standard and guideline in required VCUs is expected to achieve the beneficial effects of residual habitat structure that were intended by goshawk standards and guidelines in the 1997 Plan. Additionally, clumped configurations provide an increased measure of operability from a timber harvest standpoint.

An additional feature of the legacy standard and guideline is that it is scaled to take into account the cumulative effects from past and planned forest harvesting. The legacy standard and guideline need not apply in low and moderate risk watersheds, where cumulative effects are low, because protection is afforded by other measures such as non-development LUDs, old-growth reserves, and standards and guidelines designed primarily to address other resource concerns. In high-risk watersheds, where cumulative effects are greater, the legacy standard and guideline provides additional protections, above those other measures. As was intended by the original goshawk standards, the new approach will retain important forest structure where it is most needed, in the higher-risk VCUs. The legacy standard and guideline applies to 49 VCUs across the Forest, including 31 on Prince of Wales Island. This compares to 22 VCUs under the 1997 Plan, under which the goshawk foraging standard applied only to that Island.

I believe that the potential effects to goshawks described in the Final EIS for the 2008 Tongass Forest Plan Amendment are fully consistent with the November 2007 status finding by the FWS. I also believe that the amended Forest Plan provides as much protection for goshawks as was provided by the 1997 Plan. That Plan was estimated to provide a high likelihood of maintaining viable populations of goshawks, even before the goshawk foraging standard and guideline was added to further reduce risk. Moreover, in my view the estimate of viability risk is based on extremely conservative assumptions. This level of risk to goshawk viability would result from this Plan only under the following conditions: timber is harvested annually for 100 years at levels near the maximum allowed, and any needed corrections identified through monitoring and evaluation are not acted on. I believe that such conditions are highly unlikely. During the time the 1979 Forest Plan was in effect, annual harvest levels averaged 60 percent of the maximum level allowed. Since the 1997 Plan was implemented, annual harvest levels have been about one-third of the maximum allowed, and young-growth stands have developed suitable habitat conditions for goshawks faster than predicted. Under the amended Forest Plan, timber may continue to be harvested at rates less than the maximum allowed. A more detailed explanation of the potential effects of the amended Forest Plan is provided in Chapter 3 and Appendix D of the Final EIS.

Alexander Archipelago Wolf

In this decision the Forest Service maintains its commitment to the conservation of the Alexander Archipelago wolf. We will continue to work closely with the Alaska Department of Fish and Game and the FWS on issues related to wolf conservation in Southeast Alaska. Details on how the amended Forest Plan will provide a high likelihood of maintaining viable wolf populations in Southeast Alaska are provided in Appendix D and Chapter 3 of the Final EIS.

This decision does adopt some minor changes to wolf standards and guidelines to improve their effectiveness with respect to near-term and long-term wolf viability concerns described in the 1997 Forest Plan EIS. These changes relate to density thresholds of deer, a primary prey species of wolves; and to potentially unsustainable human-induced mortality.

Long-term maintenance of a deer herd, capable of providing sustainable wolf populations, is an important management objective in the Tongass Forest Plan. The 1997 Plan included a standard and guideline setting a deer population objective, where possible, sufficient to maintain sustainable wolf populations. The amended Forest Plan updates this standard and guideline to reflect new information from wolf research in Southeast Alaska. Additional information is provided in Chapter 3 and Appendix D of the Final EIS.

Another concern in some areas is the potentially unsustainable level of hunting and trapping of wolves, when both legal and illegal harvest is considered. The 1997 Forest Plan EIS acknowledged that open road access contributes to excessive mortality by facilitating access for hunters and trappers. Landscapes with open-road densities of 0.7 to 1.0 mile of road per square mile were identified as places where human-induced mortality may pose risks to wolf conservation. The amended Forest Plan requires participation in cooperative interagency monitoring and analysis to identify areas where wolf mortality is excessive, determine whether the mortality is unsustainable, and identify the probable causes of the excessive mortality.

More recent information indicates that wolf mortality is related not only to roads open to motorized access, but to all roads, because hunters and trappers use all roads to access wolf habitat, by vehicle or on foot. Consequently, this decision amends the pertinent standard and guideline contained in Alternative 6 as displayed in the Final EIS in areas where road access and associated human caused mortality has been determined to be the significant contributing factor to unsustainable wolf mortality. The standard and guideline has been modified to ensure that a range of options to reduce mortality risk will be considered in these areas, and to specify that total road densities of 0.7 to 1.0 mile per square mile or less may be necessary. The wolf standard also requires that both access management on National Forest System lands, and harvest regulations for hunting and trapping, be considered in relation to wolf management objectives.

Chapter 3 and Appendix D of the Final EIS contain details on these plan components relating to wolf viability. I am confident that these measures will ensure adequate protection to sustain viable populations of the Alexander Archipelago wolf. The Forest Service will continue to work closely with the State of Alaska to gather and apply new information to help resolve any future concerns about wolf management.

Endemic Mammals

This decision continues to give special management consideration to animal taxa that are known or suspected of being endemic to Southeast Alaska. Efforts have increased since 1997 to document the distribution of endemic mammals on the Tongass. Forest Service partnerships with other agencies and universities have significantly increased our knowledge of many species. However, gaps remain in the knowledge base, and there is continued concern about risks to species that may be endemic to islands within the Alexander Archipelago.

This decision brings forward from the 1997 Plan the conservation measures for habitat connectivity (described in previous sections), as well as the standards and guidelines for landscape connectivity and endemic terrestrial mammals. This decision also adopts minor changes to these standards and guidelines. For example, it clarifies that the original intent of the landscape connectivity standard was to provide connectivity between large and medium old-growth reserves. As described in an earlier section, enhancements in the network of small old-growth reserves provide protections to important habitat "pinch points," and give additional consideration to connectivity at the watershed scale. The endemic terrestrial mammal standard was modified to allow the use of existing inventory data on endemic mammal distribution when analyzing effects of proposed management projects. Surveys would still be necessary where existing information is not adequate to assess project-level effects.

American Marten

The 1997 Forest Plan EIS estimated that Alternative 11 as displayed in that EIS had a moderate likelihood of maintaining viable populations of American marten across the Tongass for 100 years, even if timber were harvested and roads constructed at the maximum levels allowed by Alternative 11 for that entire period. This moderate likelihood estimate did not take account of additional conservation measures that were added in the subsequent ROD. Alternative 11 was selected in the 1997 ROD, and modified to further reduce risk to marten viability. Several protective measures for marten habitat were added, including a standard and guideline relating to timber harvest practices. The intent of the 1997 marten standard and guideline was to reduce risk in five biogeographic provinces. Marten were judged to be vulnerable in these provinces because large areas of young conifer growth lack the residual old-growth forest structure that is known to be an important marten habitat feature. The standard and guideline aimed to avoid the creation of additional, significant gaps in marten habitat that would limit marten movement and population interactions. It required the retention of downed logs, snags, and green trees to reduce adverse effects of timber harvest on marten habitat, based on research findings that show higher marten use in partially logged areas than in clearcut areas that lack large-wood structure.

Healthy marten populations persist on the Tongass. Recent information suggests that marten populations are stable or increasing across most of the Tongass. Areas on the Tongass with the highest levels of prior timber harvest continue to have stable or increasing marten populations; for example, on Chichagof Island and Prince of Wales Island. Trapping regulations have not changed significantly on the Tongass, indicating the marten supply remains stable. In an earlier section I expressed my view that the viability panel assessments were highly conservative, reflecting a "worst-case scenario." While I am mindful that there are some long-term viability risks associated with the amended Forest Plan, I believe those risks are very small and would only occur if timber were harvested at or near the maximum rate allowed under the Plan throughout the 100-year time horizon.

Recent marten studies in Southeast Alaska confirm the scientific basis for the finding in 1997 that an old-growth reserve system represents a model of marten conservation, especially when supplemented by additional measures to protect habitat in areas where timber harvest is allowed. Studies show that marten home ranges include some areas where timber harvest and roads have reduced the old-growth cover. These and other studies indicate that the quality and quantity of available prey are very important factors influencing marten abundance and distribution.

Reflecting these findings, the amended Forest Plan incorporates three changes that affect marten habitat. First, it adopts the enhancements to the network of small old-growth reserves and the increases in other non-development LUDs that I have already described. Second, it incorporates the Forest-wide legacy standard and guideline as a replacement for the marten standard and guideline. And third, it clarifies when to consider road density management for marten.

As previously mentioned, research supports the network of old-growth reserves as the critical foundation for marten conservation on the Tongass National Forest. Enhancements in the network of small reserves, coupled with the 1,000-foot wide beach buffers and other measures for habitat connectivity, also favor the outlook for marten conservation.

I have already described the change to the legacy standard and guideline in the section on the Queen Charlotte goshawk. Adoption of the legacy standard and guideline will retain important forest structure where it is most needed, in the higher-risk VCUs throughout the Forest. The residual structure is expected to serve as suitable foraging and dispersal habitat for marten in the short term, reducing adverse effects of timber harvest on marten habitat.

Marten encounter a mosaic of habitat conditions in Tongass landscapes, including natural patterns of fragmentation associated with muskegs, windthrown stands, and other openings. While marten spend most of their time in mature and old-growth forests, studies have documented marten movements through a variety of habitats including non-commercial forest and clearcuts with established conifer cover. When applied in a typical timber sale layout, the legacy standard and guideline should produce a mix of openings and clumped residual trees. When the riparian buffers and various other standards and guidelines are factored in, most timber sale units will show a significant presence of residual-tree patches. I anticipate that the patchy character of harvest units, embedded within managed watersheds in which old growth is retained for a variety of reasons including operational constraints and beach and riparian buffers, will provide habitat conditions adequate to sustain marten prey populations. Forest Plan monitoring will check to ensure that old-growth structure is retained within units as directed by the legacy standard and guideline. Adjustments can be made through adaptive management if monitoring determines that habitat objectives are not being met.

The 1997 Plan contained a Forest-wide marten standard and guideline relating to road density. This standard is clarified in the amended Forest Plan, as follows. Road access is to be considered as an issue for marten management only when there is evidence that mortality is exceeding sustainable levels and that human access on roads is the most significant factor causing this trend. The intent of the standard does not change; rather, the change makes it clearer as to when the standard should be implemented. Other minor edits do not change the intent of the standard, but offer clarifications to support more consistent implementation. The Forest Service will continue to work closely with the State of Alaska to gather new information about marten mortality so that future concerns may be addressed in a timely and collaborative manner.

The mosaic of marten habitat that will be protected under the amended Forest Plan is similar to the marten habitat protection analyzed by the 1997 risk assessment panels, except that the network of old-growth reserves has been enlarged. Connectivity between reserves will be provided by riparian and beach fringe buffers, based on studies that report preferential marten use of riparian zones. The development LUDs will retain significant old-growth habitat. An average of 68 percent of the existing productive old growth (54 percent of what existed before commercial timber harvest began) will remain unharvested in the development LUDs, even if timber is harvested annually at the maximum allowable level for 100 years. Forest wide, 91 percent of existing productive old growth would remain after a century of maximum-rate harvest (83 percent of what existed before commercial timber harvest began). The percent of old growth remaining will vary by biogeographic province; however, VCUs within the highest-risk provinces will have additional protections afforded by the legacy standard and guideline. In addition to these habitat measures, road access will be managed to reduce marten mortality where this factor constitutes a significant risk. Collectively, the various elements of the Tongass marten strategy are expected to increase the likelihood of maintaining viable marten populations throughout the Forest. While habitat gaps may occur, the likelihood that these would cause significant isolation among marten populations is low. The anticipated transition to second-growth harvest, combined with thinning conducted for wildlife in young-growth stands, should improve the conservation picture for marten and their prey in future decades.

I believe that the potential effects to marten described in the Final EIS for the 2008 Tongass Forest Plan Amendment are well within the range of effects predicted in 1997. The 1997 Tongass Forest Plan EIS estimated there would be a moderate likelihood that marten populations would remain viable throughout the Tongass, before marten and landscape connectivity standards and guidelines were added in the 1997 ROD to further reduce risk. The amended Forest Plan also reduces risks to marten viability through increased protective measures for marten above and beyond what the viability panels assessed. These additional measures include increased old growth acres retained in both old growth reserves and other non-developments LUDs; retention of the marten road density and landscape connectivity standards and guidelines; and the addition of the legacy standard and guideline. Furthermore, the level of risk to marten viability described in the 1997 EIS would be realized only under a certain set of conditions, as follows. Timber harvest occurs at or near the maximum limits every year for the next 100 years, and any needed corrections identified through monitoring and evaluation are not acted upon. I believe these are extremely conservative assumptions. Annual timber harvest levels under the 1979 Forest Plan averaged 60 percent of the maximum level allowed. Under the 1997 Plan, annual harvest levels have fallen to 32 percent of the maximum allowed. Timber may continue to be harvested at levels below the maximum allowed under the amended Forest Plan.

For all these reasons, I am confident that the direction implemented by this decision will provide for viable populations of marten across the Tongass.

Management Indicator Species

Both the 1997 Forest Plan and the 2008 Tongass Forest Plan Amendment were prepared under the 1982 NFMA planning regulations, which required the identification of management indicator species in forest plans. This requirement was based on an assumption that the responses of selected species to land management activities could indicate the likely responses of other species with similar habitat requirements. The 1997 Tongass Plan identified 13 terrestrial and 4 aquatic management indicator species. All the terrestrial management indicator species are associated with the coastal spruce and hemlock forests that represent 98 percent of total productive old-growth on the Tongass. The 1997 Plan also specified what monitoring information should be gathered annually and evaluated after 5 years to see whether population trends could be detected, and how those trends might relate to management of the Tongass National Forest. The requirements for monitoring population trends and management relationships are contained in the applicable NFMA planning regulations. The amended Forest Plan retains all 17 management indicator species.

Fish Habitat

The Tongass National Forest contains outstanding fish habitat and aquatic resources. These resources support major subsistence, recreational, and commercial fisheries, as well as traditional and cultural values. Abundant rainfall, streams with glacial origins, and watersheds with high stream densities provide an unusual number and diversity of freshwater fish habitats. These abundant aquatic systems of the Tongass provide spawning and rearing habitats for the majority of fish produced in Southeast Alaska. Maintenance of this habitat, and associated high-quality water, is of great interest to several State and Federal natural resource agencies, as well as user groups, Native organizations, and individuals.

Many of the standards and guidelines in the 1997 Forest Plan were based, to a large extent, on the recommendations of the Anadromous Fisheries Habitat Assessment (AFHA). AFHA is considered the most comprehensive scientific review available for the Tongass. The 1997 ROD noted that the standards and guidelines and other direction included in the 1997 Forest Plan meet or exceed all of the recommendations by AFHA.

In general, the effects of implementing the amended Forest Plan on fish resources are expected to be at or below those predicted for the selected alternative in the 1997 Tongass Forest Plan Final EIS. I believe that the 1997 Forest Plan's direction regarding protection of fish habitat will continue to maintain high-quality fish resources on the Tongass; therefore, no changes were made.

Conclusion

Our understanding of the biological diversity of the complex old-growth ecosystem of the Tongass National Forest, including its composition, function and structure, is continually growing. Given the complexities involved, management decisions necessarily will involve some degree of uncertainty. This uncertainty can be mitigated to a large degree by developing an adaptive management approach based on a strong partnership with the State of Alaska and other Federal agencies to actively monitor ecosystem functions, fish and wildlife habitat, and populations. Based on my review of the record, including the Final EIS and Appendix D, I find that the old-growth strategy and specific species management prescriptions represent a balance of fish and wildlife habitat conservation measures which consider the best available scientific information. Accordingly, I find that the amended Forest Plan will provide fish and wildlife habitat to maintain viable populations of vertebrate species in the planning area and maintain the diversity of plants and animals, within an acceptable level of risk inherent in projecting management effects. Furthermore, the amended Forest Plan has a high likelihood of sustaining populations Forest-wide for the continued subsistence, recreational, and commercial uses of fish and wildlife species.

Recreation and Tourism

The potential effects of the proposed Forest Plan alternatives on recreation and tourism are evaluated in the Recreation and Tourism section of the Draft and Final EIS documents. As stated in a number of locations in that section, recreation and tourism in Southeast Alaska and on the Tongass are influenced by a number of factors that are largely independent of forest management decisions. While it is difficult to predict future recreation and tourism demand with precision, the number of visitors to Southeast Alaska, particularly cruise ship visitors, is generally expected to remain at current levels or continue to increase. Southeast Alaska residents also place a high value on the quality and availability of outdoor recreation opportunities on the Tongass. Although there is limited information that quantifies resident and non-resident recreation use, I know that residents and visitors alike seek a wide spectrum of recreation activities – some people enjoy activities requiring vast and remote areas in a natural setting, while others prefer developed facilities, utilities, and easy access. From a management perspective, the requirements of these activities are often at odds with one another and sometimes with other Forest management activities, including timber harvest and associated road construction and road management.

The potential effects on the supply of recreation opportunity settings are easier to predict, because they are affected by land management decisions to the extent that different LUD classifications influence potential recreation opportunity spectrum (ROS) classes and, therefore, different types of recreation. As indicated in the Final EIS, the general trend across all alternatives is toward an increase in developed and/or motorized opportunities and a corresponding decrease in primitive recreation opportunities. In regard to the Selected Alternative, approximately 79 percent of the Forest would fall within the Primitive or Semi-Primitive ROS classes, compared with approximately 89 percent at present. Approximately 18 percent of the Forest would fall within the Roaded Modified ROS class, compared to 10 percent at present. These changes would occur gradually over the next 150 years, and would be lower in magnitude if future development does not occur at the maximum levels allowed by the Forest Plan.

It is important to note that recreational opportunities do not cease to exist as a result of management activities such as timber harvest and road construction. Rather, changes in the supply of recreation opportunities could result in changes in recreation demand and use patterns. Southeast Alaska residents and visitors seeking solitude and isolation in a natural setting may be displaced to other areas of the Forest where the setting and use patterns are more in line with their expectations. This effect is a result not only of projected timber harvest and road development, but also due to the increases in resident population and tourism that are expected to occur under all of the alternatives. Nearly three quarters of the Forest will remain untouched by development activities, even if such activities are conducted at the maximum rates allowed under the Plan for 100 years. As described in detail in Chapter 3 of the Final EIS and in the section of this ROD dealing with the protection of roadless areas, only one-quarter of the land in inventoried roadless areas is allocated to development LUDs, and only 3 percent is included in the suitable land base. Finally, development in higher value roadless areas will be deferred under the Timber Sale Program Adaptive Management Strategy unless the level of timber harvest rises to the point where such development is warranted. In this fashion, the amended Forest Plan, in conjunction with the Adaptive Management Strategy, protects the areas most commonly identified as most valuable for primitive recreation.

Those seeking more developed areas and easier access may find increased recreational opportunities as forest management activities in development LUDs increase road access and facilitate more developed recreation opportunities. Forest-wide standards and guidelines for recreation and tourism remain substantially unchanged under the amended Forest Plan, and will guide the development of new recreation facilities. The amended Forest Plan also protects the scenic quality of heavily traveled cruise ship corridors and recreation and tourism use areas.

The amended Forest Plan is consistent with national travel management policy by requiring each Ranger District to identify and designate those roads, trails and areas that are open to motor vehicle use. This will require extensive public involvement and coordination. Working with forest users, government officials, and tribal entities at the local level is the most effective way to make route designation decisions. The Forest Service will continue to work with the State of Alaska regarding access and travel management planning and implementation.

In summary, my decision provides for a mix of recreation opportunities, with a wide range of recreation settings and experiences available throughout the Forest. It balances the competing demands of providing sufficient timber for a sustainable forest products industry while also meeting the various and wide-ranging recreation demands and user needs of Southeast Alaska residents and visitors and the recreation and tourism industry.

Market Demand

Introduction: This was key issue 2 in the EIS for the 2008 Tongass Forest Plan Amendment. This section reviews the extensive work done to respond to the findings of the Ninth Circuit court regarding the error made in 1997 in interpreting projections of market demand for timber from the Tongass National Forest. It also describes how I considered other factors related to market demand.

I understand that estimating long-term market demand is inherently uncertain. This is the primary reason I am adopting the Tongass Timber Sale Program Adaptive Management Strategy, which restricts timber harvest and associated road construction activities to the lower quality roadless areas of the Tongass unless the level of timber harvested warrants allowing such activities to take place in higher quality roadless areas that are perceived by many as more environmentally sensitive.[14] Thus, the Strategy addresses the inherent uncertainty in estimating the long-term future demand for timber. By no means does this render the substantial work done to correct the errors found by the court unimportant. It does, however, minimize the harm from any potential errors in forecasting timber demand. I believe the Final EIS fully remedies the problems identified by the Ninth Circuit regarding the treatment of market demand in the 1997 Tongass Forest Plan EIS. I recognize, however, that there are differences of opinion on long-term forecasts of market demand. The Tongass Timber Sale Program Adaptive Management Strategy is the most reasonable way to address such differences of opinion and provide the flexibility required in the face of such uncertainty. In doing so, the Strategy makes the differences of opinion regarding market demand less relevant to the decision to adopt Alternative 6.

Background—Tongass Timber Reform Act: The debate concerning the market demand for timber from the Tongass National Forest, and how the timber program relates to market demand, has been ongoing for decades. Forest Service economists with the Pacific Northwest Research Station completed their first study of the issue in 1990. Later that year, Congress enacted TTRA, which in Section 101 amended Section 705(a) of the Alaska National Interest Lands Conservation Act to read as follows:

> Subject to appropriations, other applicable law, and the requirements of the National Forest Management Act of 1976 (Public Law 94-558), except as provided in subsection (d) of this section, the Secretary shall, to the extent consistent with providing for the multiple use and sustained yield of all renewable forest resources, seek to provide a supply of timber from the Tongass National Forest which (1) meets the annual market demand for timber from such forest and (2) meets the market demand from such forest for each planning cycle. 16 U.S.C. 539(d)(a).

Questions about how to interpret and apply this direction slowed the development of procedures to comply with it. In the ROD for the 1997 Forest Plan, the Regional Forester directed that procedures be developed "to ensure that annual timber sale offerings are consistent with market demand."

[14] See the section of this ROD on minimizing effects on roadless areas for a discussion of the terms "higher value" and "lower value" roadless areas.

Those procedures were completed in 2000, and have become known as the "Morse methodology" after their author. These procedures are based on the premise that:

- Forest product markets are volatile, especially in the short run.
- Timber purchasers in Southeast Alaska have few alternative suppliers of timber if they cannot obtain it from the Tongass National Forest. Oversupplying this market has relatively few adverse economic effects; undersupplying it can have much greater negative economic consequences.
- It takes years to prepare National Forest timber for sale, including completion of environmental impact statements.
- It is difficult to estimate demand for timber from the Tongass, even a year or two in advance.
- Industry must be able to respond to rapidly changing market conditions in order to remain competitive.

Accordingly, the Morse methodology establishes a system that seeks to build and maintain sufficient volume of timber under contract[15] to allow the industry to react promptly to market fluctuations. Industry actions such as annual harvest levels are monitored and timber program targets are developed by estimating the amount of timber needed to replace volume harvested from year to year. The Morse methodology is adaptive, because if harvest levels drop below expectations and other factors remain constant, future timber sale offerings would also be reduced to levels needed to maintain the target level of volume under contract. Conversely, if harvest levels rise unexpectedly, future timber sale targets would also increase sufficiently to ensure that the inventory of volume under contract is not exhausted. By dealing with uncertainty in a flexible, science-based fashion, the Morse methodology is an example of adaptive management. The Forest Service adopted the Morse methodology as the means by which the agency complies year-by-year with the annual demand portion of the TTRA "seek to meet" requirement. Similarly, the agency intended to comply with the requirement to seek to meet demand "for each planning cycle" through a series of annual applications of the Morse methodology.[16]

In its 2005 decision, the U.S. Court of Appeals for the Ninth Circuit opined on the interpretation of TTRA. The court determined TTRA "imposed additional planning requirements for the Tongass." Among the requirements, according to the appellate court, "Congress imposed a unique duty on the Forest Service to consider the 'market demand' for timber" in Section 101 of TTRA." Further, the court stated that the duty to consider, or assess, market demand "can be seen as a refinement of the general requirement under NFMA that the Forest Service consider timber harvest as one of the goals to be balanced with environmental preservation and recreational use."

The court also found that reason and logic support a linkage between the ASQ of the Forest Plan and market demand. According to the court, "[A] ceiling too low to satisfy demand could compromise one of NFMA's multiple-use goals (timber harvest) without justification in this record." However, the court specifically noted: "[W]e do not suggest that an ASQ can never be too low to satisfy market demand, or that the Forest Service must in fact *meet* demand (as opposed to *seek* to meet market demand)." Likewise, the court stated, "a ceiling higher than needed to satisfy demand, could compromise another of NFMA's multiple-use goals (environmental preservation) without justification in this record." However, the court expressly left open the possibility that the Forest Service could adopt an ASQ greater than even the highest market demand scenario in order to allow flexibility to respond to changes in market demand, so long as the record shows "how much greater the ASQ would need to be, or to what extent other alternatives might have been considered in detail, in relation to the actual market demand."

---

15 Volume under contract is timber purchased but not yet harvested, the primary indicator of timber inventory available to the industry.

16 Adoption of the Forest Plan Amendment and the Timber Sale Program Adaptive Management Strategy do not require any changes in the Morse methodology for estimating annual timber sale offer levels. In particular, the Strategy limits the land area within which the Tongass timber program may operate, not the level of volume to be planned or offered for sale. The Morse methodology was updated, however, to incorporate new derived demand projections from a study described later in this section (Brackley et al).

The Role of the Forest Service's Pacific Northwest Research Station in Estimating Demand: As mentioned above, the first Pacific Northwest Research Station study of demand for timber from the Tongass was completed in 1990. As explained in Chapter 3 of the Final EIS for the 2008 Forest Plan Amendment, a second report with updated projections was issued in 1994, after one of Southeast Alaska's two pulp mills closed in 1993. When the last remaining pulp mill closed in 1997, the projections were updated again in the spring of 1997. It was these draft projections that were erroneously interpreted in the 1997 Final EIS and ROD for the Revised Tongass Forest Plan.

The Ninth Circuit court found that, because of the error in interpreting the 1997 market demand projections, the 1997 Final EIS failed to provide decision makers and the public with an accurate assessment of information relevant to evaluate the Tongass Plan. The court further found that, had the accurate market demand forecast and related potential employment and earnings information been used, an alternative may have been selected with less environmental impact and in less environmentally sensitive areas.

The Pacific Northwest Research Station prepared a new forecast of market demand for timber from the Tongass National Forest, *Timber Products Output and Timber Harvests in Alaska: Projections for 2005-25,* Allen M. Brackley, Thomas D. Rojas, and Richard W. Haynes, 2006 (Brackley et al.). This study projects the demand for timber from the Tongass,[17] derived from the demand in Pacific Rim markets for the end products manufactured from that timber. The Brackley et al. study revises projections made in the three previous reports, and reflects changes in Pacific Rim markets and the Alaska forest products sector over the last 10 years.

The study analyzes trends over a historical period of 40 years to forecast trends over 20 years in three key parameters:

1. The level of forest products imports in Pacific Rim nations. Based on other research regarding these markets, the Brackley et al. study projects that Pacific Rim imports of sawn wood products will increase over the next 20 years.
2. The share of those markets that will be supplied by North American forest products producers, which the study projects will remain constant.
3. The share of North American exports to the Pacific Rim that will come from Alaska. The analysis examines four alternative assumptions regarding future trends of the Alaskan share of North American exports to the Pacific Rim.

Each of these parameters influences demand for timber from Alaska. An increase in any one of them will increase demand in Alaska, if other influences remain constant. Likewise, a decrease in any of these parameters will decrease demand in Alaska, other things equal. Estimated trends in these three parameters result in projected demand for forest products from Southeast Alaska over two decades; other assumptions had to be made to convert these estimates into demand for timber from the Tongass National Forest. All of these assumptions are described in the study. Based on these assumptions, the study projects the market demand for timber from the Tongass National Forest under four different scenarios for the future of the Alaska wood products industry. As explained in Chapter 3 of the Final EIS, these scenarios are as follows:

Scenario 1—Limited Lumber Production. The goal of this scenario is to depict the situation the industry has faced over the last several years. It assumes no change in the Alaskan share of North American exports to the Pacific Rim, and no change in the North American share of Pacific Rim imports. Thus, the only increase in demand is a gradual rise resulting from growth over two decades in Pacific Rim imports, which are assumed to return to the levels of Japanese imports in 1997. It assumes there will continue to be very little market for two decades for low-grade sawlogs harvested from the Tongass, and no market for utility logs. The lack of a market for low-quality material (low-grade sawlogs and utility volume) raises the operating costs of Alaskan sawmills per unit of product,

[17] The report projects demand for timber from Alaskan national forests. Because the Chugach National Forest, the only other national forest in Alaska, has no commercial timber program, demand for national forest timber in Alaska equates to demand for timber from the Tongass.

making it more difficult for them to compete in global markets with their counterparts in the Pacific Northwest and Canada.

Scenario 2—Expanded Lumber Production. In this scenario, some form of demand stimulus is assumed, such that Alaskan producers' market share of North American exports to the Pacific Rim rises somewhat, returning to a level experienced in the last decade. Such a demand stimulus could come from an industry marketing program, capital investment to make existing sawmills in Alaska more efficient, a change in policy, or some other event that enhances the competitive position of Alaskan producers relative to their competitors in the continental United States, or a combination of such developments. Other assumptions under this scenario are the same as under Scenario 1.

Scenario 3—Medium Integrated Industry. In this scenario, events are assumed to occur that stimulate demand and develop a market for low-quality material, such that Alaskan producers' market share of North American exports to the Pacific Rim rises more quickly than under Scenario 2. Development of a market for low-quality material is referred to as an integrated industry, because all of the material resulting from timber harvest would be processed into marketable products. This is displayed as the construction of a medium-density fiberboard (MDF) plant, but the authors make it clear that an MDF plant is only one way a use for low-quality material could develop.

Scenario 4—High Integrated Industry. This scenario also assumes demand-stimulating events resulting in the development of a market for low-quality material. It also assumes that the Alaskan market share of North American exports to the Pacific Rim rise steadily over two decades.

The Brackley et al. study displays the alternative projections of derived demand for timber from the Tongass National Forest in Table 3 of the report. For the first two scenarios, which assume no market for low grade sawlogs and utility volume, the figures in that table includes sawtimber only. For the two integrated industry scenarios, the projections include total volume, including both sawlogs and utility. Utility volume must be cut down along with higher-quality timber even if there is no demand for it. It is the total volume of timber cut on the Tongass that is of most interest, in part because environmental effects result from total volume cut. In addition, any comparison of scenarios must be based on comparable figures. Accordingly, the table below (from Chapter 3 of the Final EIS) shows Brackley et al. projections for all four scenarios in terms of total volume:

Recent Developments: The Brackley et al. study was published in July 2006. In March 2007, I approved a new policy under which timber purchasers may ship to the lower 48 states unprocessed certain small-diameter and low-quality logs harvested from the Tongass, up to 50 percent of the volume harvested on each sale. This interstate shipments policy places purchasers of Tongass National Forest timber sales on a more level playing field with their counterparts in the Lower 48, where there is no restriction on interstate shipments of any timber harvested from National Forest System lands. This policy creates a market opportunity for low-quality material that the Brackley et al. study assumed would not be utilized under scenarios 1 and 2. While it is still early in the implementation of the new policy, we expect that full implementation of it over the next few years will make Alaska forest products producers more competitive with their counterparts in the Lower 48 States, because it creates a market for low grade and small diameter sawtimber and possibly for utility volume. That may allow Alaska producers to increase their share of domestic forest products markets, which would stimulate demand for timber from the Tongass without the construction of new processing facilities in Southeast Alaska, until adequate volume is available to do so.

Table 3
Volume of Tongass National Forest Timber that Must be Cut to Supply Derived Demand Reported in Brackley et al. (Million Board Feet)

	Projected National Forest Timber Harvest—Alaska (MMBF; includes Sawlog, Utility, and Shipments from Alaska)[1]			
Year	Scenario 1. Limited Lumber	Scenario 2. Expanded Lumber	Scenario 3. Medium Integrated	Scenario 4. High Integrated
2007	49.8	61.9	67	67
2008	49.8	66.4	139	139
2009	51.3	72.4	151	151
2010	52.8	78.5	166	166
2011	52.8	84.5	184	184
2012	54.3	90.5	204	286
2013	55.8	98.1	204	291
2014	57.3	105.6	204	295

Notes:
[1] These figures include total volume that would need to be cut to meet the demand projected by Brackley et al.

The Pacific Northwest Research Station recently completed an addendum to the Brackley et al. study,[18] which responds to public comments on the 2006 study, and events since that study was completed. The conclusion of the Addendum states that:

> Given the Region 10 shipment policy, the restarting of the veneer mill, and the success of Alaska producers in niche or specially markets, our current appraisal is that demand for national forest timber in Alaska is on a trajectory more similar to the scenario 2 (expanded lumber production). The down side of this development is, however, that part of the harvest is moving to mills outside southeast Alaska that have the technology to produce high volumes from small material. In our projections we assumed that the new technology would move to southeast Alaska. Regardless, the changes have the potential to create higher returns to the mills in southeast Alaska. Challenges still remain with the utilization of utility logs due to a limited fiber market. Until such markets evolve, it is difficult to see the evolution of an integrated industry characteristic of scenarios 3 and 4.

Other Studies: As described in Chapter 3 of the Final EIS, the Forest Service has considered other reports and analyses related to demand. These include a study of installed mill capacity completed by the McDowell Group et al for the Southeast Conference in 2004; recent sales and harvest figures; and estimates of the minimum timber volume required by various processing facilities made by the Juneau Economic Development Council and a subcommittee of the Tongass Futures Roundtable. These indicators offer a wide range of estimates of market demand for timber from the Tongass National Forest. While I considered all of these indicators, I relied most heavily on the Brackley et al.

[18] Brackley, Allen M. and Haynes, Richard W. 2007. Timber Products Output and Timber Harvests in Alaska: An Addendum. Res. Note PNW-RN-XXX. Portland, OR: U.S. Department of Agriculture, Forest Service, Pacific Northwest Research Station. XX p.

study, and the Addendum to that study, because they are the only peer-reviewed scientific analyses of market demand for Tongass timber, and because they are the only studies that estimate demand derived from demand for end products. As described in the section of this ROD on the need for an integrated forest products industry in Southeast Alaska, the studies by the McDowell Group and the Juneau Economic Development Council are most helpful in considering what the supply needs for such an industry would be.

Public Input. We received numerous comments from the public regarding timber supply and seeking to meet market demand. Some reviewers expressed the view that market demand for timber from the Tongass National Forest is 360 MMBF of economic timber volume, that recent harvest levels reflect solely supply constraints, and that selecting any alternative with an ASQ below 360 MMBF would unnecessarily constrain the growth of the timber industry, resulting in significant adverse consequences for the economy of Southeast Alaska.

I believe the most likely demand scenario to develop over the next 15 years is for annual market demand to reach 187 MMBF by 2022. The Brackley et al. study describes significant challenges for the industry in reaching Scenario 4, under which market demand is projected to reach 360 MMBF in 2024 and 370 MMBF in 2025. The Addendum to that study reiterates the challenges that make scenarios 3 and 4 unlikely to occur. Among these are a resolution of the supply constraints related to appeals and litigation, and an investment climate perceived as favorable. Other reviewers point out that timber operators in Alaska have considerably higher labor and transportation costs and face other competitive disadvantages relative to their counterparts in the Lower 48 States, which negatively affects the investment climate in the Alaska forest products sector. In addition, the studies most often cited to support the assertion that market demand for Tongass timber is 360 MMBF were based almost exclusively on mill capacity rather than derived demand for manufactured products. The Brackley et al. study is the only derived demand study. Accordingly, I view the other studies more as analyses of timber supply needed to operate current and potential future mills, rather than projections of market demand.

For all these reasons, I believe that the ASQ of the selected alternative will provide an opportunity for the growth of an integrated and competitive timber industry over the next 10 to 15 years. Moreover, if the timber industry grows more rapidly than anticipated in the next few years, such that demand exceeds the average annual ASQ of 267 MMBF, existing procedures are flexible enough to respond to this possibility. ASQ is a ceiling on the amount of timber that may be sold over a ten-year period. While it is most often expressed as an average annual figure, the ASQ of the amended Forest Plan is 2.67 billion board feet for the next decade. Thus, if less than the average annual figure of 267 MMBF is sold in the next five years, the difference could be added to the sale quantity for the remainder of the decade, up to the 10-year limit of 2.67 billion board feet.

If the demand for timber has been substantially underestimated, the forest planning process includes procedures for analyzing what is known as departure from the established ASQ ceiling, to determine whether harvesting above the ASQ level would better meet multiple-use objectives (see Forest Service Manual 1926.15 and Handbook 2409.13). These procedures include several criteria or conditions in which evaluation of departure from the ASQ would be warranted. Such consideration would be done through the normal forest planning process, which includes public involvement. One of the conditions listed is when implementation of the ASQ could have a substantial adverse impact in the economic area in which the forest is located. For example, if the level of timber harvest were to increase to the point where the cumulative amount of timber sold approached the ASQ, there may be insufficient additional sale volume to support an expansion of the industry, should an expansion such as a new processing facility be proposed. If this were regarded as too disruptive to the local economy, the Handbook allows for consideration through the forest planning and public involvement process of an alternative that departs from non-declining flow requirements. Preliminary analysis performed as part of this Amendment process has shown that a departure volume of at least 310 MMBF per year (3.1 billion board feet for 10 years) in the second decade is achievable without compromising sustained yield principles in future decades.

I am also aware of concerns that timber demand has been overestimated, and that adopting an alternative with an ASQ substantially higher than recent harvest levels could allow timber harvest and road construction in roadless areas perceived as more environmentally sensitive and therefore worthy of protection. The Timber Sale Program Adaptive Management Strategy is designed to address that concern by limiting harvest in Phase 1 to the lower quality roadless areas and deferring development activities in the higher quality roadless areas until such time as the actual harvest levels indicate a need to allow development in these areas. A more detailed description of how higher value roadless areas are protected at each phase of the Strategy is included in the next section of this ROD. The main point, however, is this: by adopting the Timber Sale Program Adaptive Management Strategy we have eliminated the potential harm to more environmentally sensitive areas from overestimating long-term market demand for timber. I am convinced that it is impossible to estimate the long-term market demand for Tongass timber with complete precision and accuracy. I am equally convinced that by adopting the Strategy, those difficulties no longer matter very much in choosing among alternatives. I feel secure in selecting Alternative 6, with an ASQ well above recent timber harvest levels, because the Timber Sale Program Adaptive Management Strategy will ensure that, at whatever level timber is harvested over the next 10-15 years, such harvest will be limited to the lowest value roadless areas possible.

Conclusion

In 1997, the Regional Forester concluded his analysis of demand issues as follows:

> Market demand is volatile; the projections done by the [Pacific Northwest Research] Station scientists have changed considerably each time they have been updated. Different economists will often make different projections of future demand because they often make different assumptions about the future (see Brooks and Haynes, June 1994, Timber Products Output and Timber Harvests in Alaska: Projections for 1992-1010, General Technical Report, PNW-GTR-334). Demand also will be influenced by whether or not businesses choose to invest in new wood-processing industries in Southeast Alaska over the next decade. Such decisions will be determined in part by investors' subjective evaluations of the certainty with which they can rely upon the Tongass as a reliable source of timber. 1997 ROD, page 25.

These statements are still applicable today.

As I review Table 3, I see annual market demand estimates that range from 50 to 139 MMBF in 2008; and from 68 to 342 MMBF in 2022. As discussed above, the Pacific Northwest Research Station economists who developed the demand projections believe the most likely outcome is Scenario 2. That suggests it is most reasonable to expect an annual demand of approximately 187 MMBF in 2022 unless the industry becomes fully integrated in the interim. It is this last figure that I found most instructive and useful for guiding my decision. As described in other sections of this ROD, I believe the selected alternative avoids conflicts with other goals, such as environmental preservation (especially wildlife viability) or recreation. The ability of the selected alternative to meet these other goals gives me the assurance I need to select Alternative 6, which allows the projected level of long-term demand to be met.

Need for an Integrated Industry

An integrated forest products industry is one that includes processing facilities and markets for all types of logs from timber harvest operations conducted in the area, and for byproducts such as chips that result from processing those logs into lumber or other products. Such integration substantially enhances the economic efficiency of a regional industry as a whole, and the competitive position of all producers relative to their counterparts in other areas. Southeast Alaska has not had an integrated industry since the closure of the region's pulp mills in the 1990s. Those mills processed utility logs, for which little or no local market has existed since those mills closed. Utility volume must still be cut down, primarily for safety reasons. The lack of a local facility to process utility volume means timber purchasers are required to cut and handle logs that they must often leave in the woods. Thus, some of the material harvested is not utilized; producers' operating costs are increased per unit of material they do process; and the industry's competitive position is diminished.

Consequently, the lack of an integrated industry increases the economic incentive to harvest high-volume timber stands disproportionately in order to make timber sales economic.

The lack of facilities in Southeast Alaska to process low-grade and small-diameter material also makes it more difficult to conduct commercial thinning of young-growth timber stands. Because funding for pre-commercial thinning projects has historically been insufficient to meet the need, commercial thinning is the most feasible way to improve wildlife habitat quality and restore other ecological values in areas previously harvested. Some of these areas have significant restoration needs because they were harvested decades ago under standards considerably less protective than they are today. The absence of processing facilities in Southeast Alaska for the small-diameter material from these stands makes such restoration more difficult to accomplish.

Further, an integrated industry could enhance the quality of life in Southeast Alaska by providing for a sector of sustainable, year-round, family-wage jobs in rural, resource-dependent communities. When added to existing industries such as recreation and nature tourism, commercial and recreational fishing, and government employment, an integrated wood products industry could contribute to a more stable social infrastructure. This includes schools, hospitals, libraries and various service industry amenities like hotels and restaurants that support a greater quality of life for Alaska residents.

Consequently, re-developing an integrated industry is an important part of the ecological, economic and social components of sustainability. Timber production has been one of the missions of the National Forests since enactment of the Organic Administration Act in 1897. If we are to sustain this industry in Southeast Alaska, we must provide opportunities for local processors to expand and integrate enough to compete more effectively in world markets. Integration would also enhance ecological sustainability by reducing the amount of material now left in the woods and facilitating the transition to an industry based more on young-growth stands. For all these reasons, I believe it is important to provide opportunities for the re-establishment of an integrated forest products industry in Southeast Alaska, capable of processing all types of timber products available from the Tongass.

Having determined that it is important to provide an opportunity for the timber industry to become more integrated, the question arises as to what supply from the Tongass National Forest would be needed to accomplish that objective. There are many sources of information on this subject, and I considered them all. The Brackley et al. study indicates that a partially integrated industry would generate a market demand for timber from the Tongass of 204 MMBF in 2022, and a fully integrated industry would demand 342 MMBF.

As mentioned in the market demand section of this ROD, a recent analysis prepared for the Southeast Conference—"Timber Markets Update and Analysis of an Integrated Southeast Alaska Forest Products Industry" (McDowell Group et al. 2004)—also studied the supply needed to support an integrated timber industry in Southeast Alaska. That study considered installed capacity of Southeast mills, projected a harvest volume that would allow the mills to operate at an efficient level assuming the existence of an integrated industry, and concluded that a minimum of 200 MMBF total harvest would be required annually from the Tongass National Forest. However, the most efficient use of timber from the Tongass would most likely include other processing facilities, such as a veneer mill. The industry would be most efficient with at least two of each type of manufacturing facility because this would foster competitive bidding for materials and labor. Depending upon the types of facilities, this could require an annual harvest of 350 MMBF or more from all sources of wood. On December 30, 2006, the McDowell Group responded to a request by Southeast Conference to clarify and update key findings from the 2004 report. They concluded the study done in 2004 was still valid, including the estimate that 350 MMBF or more would be required to support an integrated and competitive industry.

The report prepared by Juneau Economic Development Council and an effort by a Tongass Futures Roundtable Subcommittee also estimate the minimum timber volume required by various processing facilities based on their potential capacity. The estimated sawmill volume is approximately 66 percent of existing mill capacity (138 MMBF annually), based on the four largest existing sawmills in Southeast Alaska, with some allowance for smaller mills. The minimum estimated annual volume necessary to supply a veneer plant is 30 MMBF of sawlogs, with 80 to 100 MMBF of No. 3 sawlogs and utility logs required to support an MDF or bioenergy facility. Using these projections, a total of 248 MMBF to 268 MMBF is the minimum annual supply necessary to support an integrated industry.

The State of Alaska has also provided information related to the supply of timber needed from the Tongass to support the reestablishment of an integrated industry. In the comments provided by the State on the Draft EIS, the Governor recommends the Tongass provide a minimum of 168 MMBF of economic sawlog timber to support reestablishment of an integrated industry.[19] When the utility volume associated with this harvest level is accounted for, this equates to an economic (or NIC I) annual harvest of approximately 200 MMBF from the Tongass. The NIC I portion of the ASQ of the amended Forest Plan is 238 MMBF annually, which is sufficient to meet the needs identified by the State.

As I consider all of this information regarding the supply needs of an integrated industry, I conclude that the amended Forest Plan will provide an opportunity for such an industry to be reestablished in Southeast Alaska. Alternatives 1 and 2 of the Final EIS would foreclose that option; Alternative 3 could meet it only during periods of strong markets, when the NIC II volume becomes economically viable. However, potential investors in additional processing facilities must make their decisions based on long-term projections that include entire market cycles. Therefore, a reliable annual supply of at least 200 MMBF of economic timber would be needed from the Tongass to meet the objective of providing an opportunity for the reestablishment of an integrated industry. None of the alternatives with an ASQ lower than the amended Forest Plan's meet that criterion.

Minimizing Effects on Roadless Areas

This issue was described in the EIS for the 2008 Forest Plan Amendment as key issue 1. As with many other issues regarding management of the Tongass National Forest, protecting roadless areas is a topic with a long history and many complexities. Consequently, we begin this discussion with terminology, then the history, before describing how the Final EIS, the selected alternative, and the Timber Sale Program Adaptive Management Strategy respond to this issue.

Terminology. The following terms are used in this ROD in discussing roadless issues:

Roadless Area: The term "roadless area" is a generic term that is sometimes used to refer to all areas without roads. (The Final EIS uses the term this way, to include all such areas.) For the purpose of this ROD, however, it is used to refer only to inventoried roadless areas to simplify the discussion.

Inventoried Roadless Area: An undeveloped area typically exceeding 5,000 acres that meets the minimum criteria for wilderness consideration under the Wilderness Act.

History. The Wilderness Act of 1964 required the Secretary of Agriculture to inventory all roadless areas within the National Forest System to determine which of them should be designated as Wilderness. Generally speaking, roadless areas must be at least 5,000 acres, or adjacent to existing wilderness, to be eligible for such designation. The Forest Service has long recognized that not all roadless areas are of equal ecological, scenic, or recreational value. Accordingly, the agency developed the Wilderness Attribute Rating System as the process to rate roadless areas according to their natural integrity, scenic quality, opportunities for solitude, and primitive recreation opportunities. The NFMA implementing regulations later incorporated the inventory requirements into the forest planning process. Lands identified through these procedures are referred to as Inventoried Roadless Areas.

A comprehensive inventory of roadless areas on the Tongass that meet the Wilderness Act's minimum criteria was completed in 1996 as part of the development of the 1997 Forest Plan. This inventory identified about 9.4 million acres of roadless land on the Tongass in 110 inventoried

[19] "Economic timber" is defined as: A fair market value sale of timber wherein the average purchaser can meet all contractual obligations, harvest and transport the timber to the purchaser's site, and have a reasonable certainty of realizing a profit from the sale.

roadless areas. No inventory is completely accurate for long, however, for a variety of reasons. National Forest System lands are sometimes conveyed to non-federal parties, such as conveyances to Alaska Native corporations under the Alaska Native Claims Settlement Act. Non-federal lands within National Forest boundaries are sometimes acquired by the Forest Service, most often through exchange for other Federal lands. Roadless areas also become developed, primarily through timber harvest and road construction allowed under the Forest Plan. Finally, geographic information system data are updated periodically. Consequently, inventories conducted only a few years apart can yield different results.

Inventories of roadless areas on the Tongass illustrate these points. The Forest Service updated the 1996 inventory in 2000 as part of the development of the Roadless Area Conservation Rule (Roadless Rule), published in 2001. The 2000 inventory identified about 9.3 million acres. The inventory was updated again in 2003 as part of the development of the Supplemental EIS regarding potential wilderness recommendation; this inventory identified about 9.6 million acres of the Tongass as roadless areas. The Final EIS for the 2008 Forest Plan Amendment updates the 2003 inventory, and identifies 9,514,185 acres in 109 inventoried roadless areas on the Tongass. A map of these roadless areas is available on the CD containing the Final EIS, and on the internet through the Forest's website at *www.fs.fed.us/r10/tongass/*.

Treatment of the Roadless Issue in the Final EIS, Forest Plan, and Timber Sale Program Adaptive Management Strategy. As discussed in the section of this ROD on the alternatives considered, the protection of higher value roadless areas was a paramount consideration in the development of the alternatives analyzed in detail in the Draft EIS. The Forest Service rated each of the 109 inventoried roadless areas on the Tongass using the Wilderness Attribute Rating System. Special consideration was also given to areas proposed for wilderness during congressional consideration of TTRA, and to areas allocated to non-development LUDS by the Under Secretary of Agriculture in the 1999 ROD that was later vacated by the court. The results of that evaluation were used to exclude higher value roadless areas from development LUDs of each alternative as much as possible, so that timber harvest and road construction activities allowed under each alternative would avoid higher value roadless areas to the extent practical, given the balance of multiple use objectives of each alternative.

Refinement of the Alternatives: During the public comment period on the Draft EIS, many reviewers recommended that timber harvest and road construction be confined to the portions of the forest where roads have already been constructed, so that all currently roadless areas would remain undeveloped. Many respondents recommended specific roadless areas be protected from development. Some conservation organizations, such as The Nature Conservancy, developed their own rankings of watersheds on the Tongass and offered lists of areas that they recommend for protection from development. Nearly all of these are within roadless areas.

Following the public comment period on the Draft EIS, the Forest Service reviewed six different ranking systems and lists of areas recommended for protection that represent a wide variety of approaches to identifying higher value areas. These include:

1. The list of High Value Community Use Areas developed by the Alaska Department of Fish and Game.
2. The 18 Areas of Special Interest identified by the Under Secretary of Agriculture in the 1999 ROD.
3. Roadless areas identified by the U. S. Fish and Wildlife Service as having outstanding or important fish and wildlife values.
4. Watersheds identified by the Southeast Alaska Conservation Council as Tier 1 or Tier 2 watersheds.
5. A list of Conservation Priority Watersheds identified by The Nature Conservancy and the Audubon Society and provided in comments on the Draft EIS.
6. Roadless areas and their relative ranking based on the Wilderness Attribute Rating System.

While there is considerable commonality among these lists, there also are some significant differences. These differences demonstrate that there is no single definitive process or criterion by which to judge the value of individual roadless areas. Accordingly, the Forest Service took all of these rating systems and lists into account in developing the Final EIS and the Timber Sale Program Adaptive Management Strategy. The Forest Service also considered logistical considerations, such as the proximity of roadless areas to developed lands, to account for social and economic values as well as biological values in the consideration of roadless values. During this analysis, the Forest Service identified three general categories of roadless areas, based largely on how frequently they are included in the above ranking systems:

- *Lower Value Roadless:* These lands are relatively small areas, and usually located within or near developed landscapes. They often lack the resource features and values found in larger and more isolated roadless areas. Because of their smaller size and proximity to developed landscapes, they often are less manageable as a roadless area by themselves, and can often be accessed by logical extensions of existing road systems. These areas usually appear on no more than 1 or 2 of the ranking lists described above. For example, the 16,000-acre East Zarembo Roadless Area on Zarembo Island is long and irregular in shape, is substantially affected by surrounding developments, and does not have high ecological or social values when compared to larger and more isolated roadless areas.
- *Moderate Value Roadless:* These areas are generally larger and often include portions with higher ecological or social values. Examples include high value watersheds, high scenic resources, or high recreational values. These areas usually appear on 3 or 4 of the ranking lists described above. The southern end of the South Kupreanof Roadless Area is a good example, in which the southwestern corner associated with Rocky Pass has very high scenic values while most of the remainder has lower values.
- *Higher Value Roadless:* These areas are often larger and usually have very high ecological and social values. These areas usually appear on 5 or 6 of the ranking lists described above. The 190,000 acre Cleveland Roadless Area is a good example.

As described in Chapters 2 and 3 of the Final EIS, the alternatives respond to public concerns regarding protection of roadless areas in a progressive fashion. Alternative 1 would allow no scheduled timber harvest or road construction in any roadless area. As alternatives progress to higher levels of allowable timber harvest and road construction, more roadless areas are allocated to the development LUDs, starting with lower and some moderate value roadless areas in Alternative 2, then incorporating mostly lower and moderate value roadless areas in Alternative 3, and more higher value roadless areas in alternatives 4 through 7.

Further Protection of Higher Value Inventoried Roadless Areas through the Timber Sale Program Adaptive Management Strategy: Based on my review of this information and the analyses presented in the Final EIS, I believe the selected alternative minimizes the adverse environmental effects on roadless areas while still seeking to meet market demand for timber from the Tongass. Just over 3 quarters of inventoried roadless acres are included in the 13.3 million acres of non-development LUDs. The Forest Plan allocates 24 percent of the inventoried roadless acres to development LUDs. Due to the additional protection offered by the standards and guidelines that apply to these LUDs, only 3 percent of the land in inventoried roadless areas would be included in the suitable land base. Finally, even if timber were harvested and roads constructed at the maximum rates allowed under the Forest Plan for 100 years, at least 80 percent of the Tongass would still remain in an undeveloped condition without roads.

I know some will still be concerned, however, that since the ASQ of the Forest Plan is considerably higher than recent harvest levels, some higher value roadless areas may still be unnecessarily harmed by including them in the development LUDs before the projected increase in long-term demand actually materializes. The Timber Sale Program Adaptive Management Strategy that I am adopting today was designed specifically to remedy these concerns. A discussion of how the Strategy was developed follows below.

After the public comment period on the Draft EIS, the Forest Service reviewed each of the roadless Value Comparison Units (VCUs, areas of land delineated for planning purposes) in the development LUDs of Alternative 6. Each of these VCUs that contains suitable lands was compared to each of the six lists of higher value roadless areas described above, to develop a comprehensive sense of the ecological, recreational, and social value of each of these VCUs. As previously mentioned, logistical challenges related to timber economics were also considered. Through this process, each VCU was assigned to one of the three phases of the Timber Sale Program Adaptive Management Strategy. Phase 1 of the Strategy is similar to Alternative 2, in that the scheduled timber sale program would be confined to areas already developed and to lower value roadless areas. Phase 2 of the Strategy, which would be implemented only if the level of timber harvest reached 100 MMBF annually for two consecutive years, is similar to Alternative 3, in that the scheduled timber sale program would be allowed to operate in some moderate value roadless areas. Phases 1 and 2 are also comparable to Alternatives 2 and 3, respectively, regarding the maximum sustainable level of timber harvest that could be supported from the amount of suitable land they include.

Only in Phase 3, which would only be implemented if timber harvest levels reach 150 MMBF for two consecutive years, would the scheduled timber harvest program be allowed to operate in higher value roadless areas. In this fashion, the Timber Sale Program Adaptive Management Strategy offers an extra level of protection for higher value roadless areas, and a more robust response to concerns related to allowing such areas to be affected by development activities prematurely.

I want to reiterate that there is no single definitive process or criterion by which to judge the value of individual roadless areas. That is why the Forest Service took into consideration the ratings of other organizations to help us design a strategy that seeks to avoid areas most often listed as high value.

Treatment of Areas of Special Interest to the Public under the Forest Plan and Adaptive Management Strategy: As described above, several conservation organizations and numerous individuals have provided input recommending protection for specific areas. The areas mentioned most frequently are listed below, with a description of how each area is treated under the selected alternative and the Adaptive Management Strategy. The map of the areas included in each phase of the Timber Sale Program Adaptive Management Strategy can be found on the on the compact disc of the Final EIS and is also available on the internet at *www.fs.fed.us/r10/tongass/*.

Port Houghton – Public comments on this area requested protection for the southern portion of the Windham - Port Houghton Roadless Area, all of the Fanshaw Roadless Area, and the western tip of the Spires Roadless Area in the South Arm of Faragut Bay, especially Port Houghton, the salt chuck at the head of the North Arm of Port Houghton, Sanborn Canal, and Faragut Bay. The majority of these areas remain in non-development LUDs under the amended Forest Plan. While some areas within the Windham – Port Houghton and the Fanshaw Roadless Areas are allocated to development LUDs, they are included in the Phases 2 and 3 of the Timber Sale Program Adaptive Management Strategy, with VCUs 790 and 840 in Phase 3. This means that until the actual level of timber harvest on the Tongass reaches 100 MMBF for two consecutive fiscal years in Phase 1, then 150 MMBF for two consecutive years in Phase 2, no timber sales could be planned for these areas.

Thomas Bay part of Spires Roadless Area –The development LUDs in the southern tip of the Spires Roadless Area and other lands near the southern portion of Thomas Bay are mostly roaded and are included in Phase 1 of the Strategy. The development LUDs (VCUs 4830 and 4840) near the northern part of Thomas Bay are mostly undeveloped and are included in Phase 2.

Kake Community Use Area and Kuiu Island – Kuiu Island and the surrounding smaller islands are important to the residents of Kake, especially the coastal areas near Kake. Areas most often associated with higher values include the Keku Islands, Kadake Bay and Creek, Port Camden, Rocky Pass, and the East Kuiu Roadless Area on the south and east side of Kuiu Island.

The Keku Islands and the lands adjacent and near Kadake Bay are in non-development LUDs. Lands adjacent to the Keku Islands in VCU 3990 have been placed in Phase 2 of the implementation strategy. This means that until the actual level of timber harvest on the Tongass reaches at least 100 MMBF for two consecutive fiscal years, no timber sales could be planned for these areas.

The adjustments to small old-growth reserves in this area also resulted in a continuous block of non-development LUDs from Kadake Bay to Saginaw Bay. Additionally, about 23 miles of Kadake Creek and other major tributary streams that flow into Kadake Bay were recommended in 1997 for designation as a Recreational River, and that recommendation is not being changed. Recreational River LUDs generally provide recreation opportunities in a pleasing, though modified, free-flowing river setting, while allowing timber harvest, transportation and other developments.

Port Camden has development LUDs on both sides of the bay, with the west side having past timber management activities and the east side mostly undeveloped. In response to public comments, the west side of Port Camden in VCU 4200 is in Phase 2 of the implementation strategy. The east side of Port Camden in VCU 4200 is placed in Phase 3, so no timber sale could be planned for this area unless timber harvest levels reach 150 MMBF for two consecutive fiscal years in the future.

Rocky Pass is nearly entirely in non-development LUDs, including the east side of the peninsula between Rocky Pass and Port Camden. The East Kuiu Roadless Area located to the south of the developed areas on the east side of the Island is placed in Phase 3.

The remaining development LUDs on northern Kuiu Island are included in Phase 1 of the Strategy, primarily because the area is mostly developed with good infrastructure and timber volumes, all of which are important for the current timber industry. I believe the overall mix of land use designations for Kuiu Island, when combined with the deferral of many parts of the development LUDs on Kuiu to Phases 2 and 3 of the Adaptive Management Strategy, provides a good balance of the commodity and noncommodity values and uses for Kuiu Island.

Upper Tenakee Inlet – In the 1997 Forest Plan, the non-development LUDs along the shoreline areas, including several inlets and bays, often resulted in blocked access or significantly increased costs of access to the development LUDs in the uplands. In reviewing the small old-growth reserves in upper Tenakee Inlet, biologists, logging engineers and managers took a hard look at this area to see if a better balance of protecting the high scenic and habitat values associated with the area while also addressing the high development costs could be made. In response, VCUs 2240 and 2250 in the upper end of the Inlet were converted to the Semi Remote Recreation LUD to address the scenic values and to strengthen the biodiversity connection, or pinch-point, with the northeastern lobe of Chichagof Island as well as the Neka Bay area. Both development and non-development LUDs along the west side of the Inlet were consolidated and the development LUDs in VCUs 2260, 2290, and 2320 are scheduled for Phase 3 of the Strategy. VCU 2310 is scheduled for Phase 2 because it is easily accessible by extending the current road system from VCU 2300.

Ushk Bay/Poison Cove – This area of very high public interest is located in the Hoonah Sound Roadless Area. Issues in this area relate to Native Allotment claims, subsistence, timber sale economics, the proximity of the area to Sitka, high cultural and traditional use values, scenic, and other uses. If development projects are proposed in the area, the amended Plan provides reasonable options and flexibility to address the high values and potentially competing uses of the area. In recognition of this area's complexity and high values, it is included in the Phase 3 of the Strategy, which means that no timber sale can be planned until actual harvest levels on the Tongass reach 150 MMBF for two consecutive fiscal years.

West Duncan Canal – The lands all along the west side of Duncan Canal are in non-development LUDs in recognition of the high recreation and scenic resources associated with the area. This width of non-development LUDs ranges from about 1 mile in width to several miles inland, such as up the Castle River drainage. The inland portions of the northern part of the area where development is allowed are included in Phase 1 of the Strategy because they are easily accessible from currently roaded areas in the interior of the island by extending existing road systems. Development LUDs associated with the southern part of the Canal in VCU 4350 are deferred until Phase 3. Most of the remaining land in development LUDs on the southern portion of the Island is in Phase 2, because these areas would be easily accessible by extending the existing road system in the interior of the Island to the north. The amended Forest Plan provides a well-balanced mix of LUDs that fully recognize the many values associated with the lands along the west side of Duncan Canal while allowing some timber harvest if and when it is needed.

Honker Divide – Honker Divide is a key part of the old-growth conservation strategy for the northern half of Prince of Wales Island, with over 200,000 acres in non-development LUDs. The strategy includes connections of old-growth habitat in non-development LUDs from the Karta Wilderness through Honker Divide and the Sarkar Lakes area and through the Calder Holbrook LUD II area to the northern tip of Prince of Wales Island. To further support the protection of this connective area, I am including the eastern portions of VCU 5750 and 5780 in Phase 2 of the implementation strategy. VCU 5740 is also deferred to Phase 2, which means no timber harvest may be planned until the actual harvest levels on the Tongass reach 100 MMBF for two consecutive fiscal years.

***Gravina and Bostwick Inlet* –** Bostwick Inlet is located on the south and east end of Gravina Island near Ketchikan. Many residents of the nearby communities of Ketchikan, Saxman, and Metlakatla use this area for recreation and subsistence purposes. Much of the land in the area surrounding Bostwick Inlet were previously allocated to development LUDs and no changes were proposed in the 2007 draft amended Forest Plan.

Many reviewers of the Draft EIS recommended no timber harvest be allowed on Gravina Island. In their comments on the Draft EIS, the Ketchikan Indian Community (KIC) expressed serious concerns with timber harvest activities previously proposed on Gravina Island, and referred to ongoing collaborative efforts to resolve those concerns. KIC recommended changing the LUDs in the Bostwick area from development to non-development. Consequently, I am modifying Alternative 6 as displayed in the Final EIS to change the LUD allocations in the Bostwick Inlet area to a combination of non-development LUDs. I am also deferring timber harvest in the development LUD to the west and south of Bostwick inlet to Phase 3 of the Timber Sale Program Adaptive Management Strategy. Only if the timber industry expands to levels of harvest sufficient to implement this last phase could timber sale planning be done for this area.

Cleveland Peninsula – The Cleveland Roadless Area has been the center of land use debates for some years. Recreation use of Cleveland Peninsula is high, especially on the eastern side of the peninsula north of Ketchikan. Some mineral exploration is ongoing on the northern side of the peninsula. The Forest Plan allocates the entire southwestern portion, roughly one-half of the area, to non-development LUDs. The remainder of the peninsula is allocated to a mix of development and non-development LUDs that recognize the old-growth habitat, scenic, and timber values of the area. I believe the mix of LUDs and associated standards and guidelines in place with the Forest Plan are appropriate to address the high values associated with Cleveland Peninsula. It is not the appropriate time to change the mix of LUDs here, primarily because of the amount of suitable and available timber included in the development LUDs. However, virtually all of the development LUD areas on Cleveland Peninsula are included in Phase 3 of the Strategy, except for VCU 7210 where the Emerald Bay project was previously proposed, which will be in Phase 2. No further timber sale planning in this area may be done until the actual harvest levels on the Tongass reach 100 MMBF for two consecutive fiscal years.

***Salmon Bay Lake* –** Most of the Salmon Bay Lake area on northern Prince of Wales Island is in a congressionally designated LUD II area. Relatively small portions of the watershed outside of the LUD II area are in development LUDs, especially in VCUs 5340 and 5341. These portions are included in Phase 2 of the Strategy, which means that no timber harvest may be planned until the actual harvest level on the Tongass reaches 100 MMBF for two consecutive fiscal years.

***Basket Bay and Kook Lake* –** This area was identified by The Nature Conservancy, the U.S. Fish and Wildlife Service, and others as having very high fish and wildlife values. The area to the north of Kook Lake in VCU 2390 is developed while the area to the south in the remainder of VCUs 2390 and 2400 is not. The development LUD portion of the southern area is included in Phase 2 of the Strategy.

***Sitka Community Use Area* –** The development LUDs in the immediate area surrounding Sitka have been heavily developed during past timber management activities. Many residents of Sitka have expressed a desire for a greatly reduced level of future timber harvest or none at all. Therefore the majority of the development LUDs have been placed in Phase 2 of the Strategy, which means that no timber harvest may be planned until the actual harvest level on the Tongass reaches 100 MMBF for two consecutive years.

Kruzof Island – The developed portion of northern Kruzof Island has become popular for recreation users from Sitka, especially taking advantage of the roaded access of the area. The Nature Conservancy and Audubon Alaska assessment efforts also recognized this area for its multiple use values and recommended the area have an integrated management emphasis. All of the Timber Production LUD in this area has been changed to Modified Landscape, which better reflects the recreation and scenic values of the area while also providing opportunities for smaller timber sales in the future. The area is also included in Phase 1 of the Strategy.

Problems Identified by the Ninth Circuit Court of Appeals

As described on page one of this ROD, the Ninth Circuit Court of Appeals identified several inadequacies with the 1997 ROD and Final EIS for the Forest Plan. Remedying those problems is the primary purpose and need for the 2008 Amendment. The section of this ROD regarding market demand explains how the Forest Service has corrected the errors made in 1997 by developing new projections of market demand. Having corrected those previous errors related to market demand, the court's supposition about choosing an alternative with less environmental effects and in less sensitive areas does not apply to this decision. Nonetheless, the discussions above on roadless areas and the Timber Sale Program Adaptive Management Strategy explain how the Forest Service has taken extra steps to ensure that potential adverse effects on areas perceived as environmentally sensitive have been minimized. The discussion below explains why I believe that Alternative 6, coupled with the Tongass Timber Sale Program Adaptive Management Strategy, best responds to the remaining problems identified by the court, those dealing with the range of alternatives considered in the Final EIS, and the cumulative effects of disproportionate harvest of high-volume timber on non-federal land.

Range of Alternatives

The Court of Appeals for the Ninth Circuit found two deficiencies related to the alternatives considered in the 1997 Final EIS for the Revised Tongass Forest Plan. The Forest Service had not considered alternatives that set the ASQ equal to the correct demand scenarios. In addition, each of the 10 alternatives considered in the EIS allocated some roadless areas to LUDs that allow development; the EIS omitted an alternative that allocated less undeveloped land to the development LUDs.

Setting ASQ of the Alternatives Equal to Projected Demand of the Scenarios. In the 1997 Final EIS, one alternative had no scheduled timber program, so the ASQ for that alternative was zero. With that exception, the ASQ of all alternatives considered in 1997 exceeded demand projections under the low and middle market scenarios of the 1997 demand study. For the 2008 Forest Plan Amendment, I considered all the demand projections of the Brackley et al. study, as displayed in Table 3, which I consider to be the best available science related to market demand projections. As previously discussed in the market demand section of this ROD, I found the projections for 2022 most helpful in guiding my decision to approve the amended Forest Plan, since that is the end of the NFMA planning cycle of 10-15 years, and three of the four demand scenarios estimate that demand will grow every year throughout the 20-year period of the study. Table 4 below compares the demand projections for 2022 with the ASQ for the second decade of each alternative considered in detail in the Final EIS.

Table 4
Projected Demand[1] in 2022 Under each Brackley et al. Scenario Compared to Second-decade Average Annual ASQ for each Final EIS Alternative

Projected 2022 demand[a] (MMBF).	Second-decade ASQ for each alternative (MMBF).
Scenario 1 – 68	Alternative 1 – 49
Scenario 2 – 187	Alternative 2 – 152
Scenario 3 – 204	Alternative 3 – 203
Scenario 4 -- 342	Alternative 4 – 360
	Alternative 5 – 267
	Alternative 6 – 267
	Alternative 7 – 421

Note:
[1] These figures include total volume (sawlog and utility) that would need to be harvested to meet the demand projected by Brackley et al.

Alternatives 1-4 were designed to correspond with scenarios 1-4, respectively. Alternative 1 was designed to reflect scenario 1, with modifications to better match recent annual harvest levels (approximately 50 MMBF) and to avoid harvesting in roadless areas and areas on Kuiu Island. Because of these modifications, the Alternative 1 ASQ is actually 19 MMBF (28 percent) below the projected demand of Scenario 1. The ASQ of Alternative 2 is 25 MMBF (19 percent) below the projected demand of Scenario 2. The purpose of Alternative 2 is to display an alternative that restricts development activities to lower value roadless areas. Alternative 3 differs from Scenario 3 by only 1 MMBF. The ASQ of Alternative 4 is 18 MMBF (5 percent) above the projected demand of Scenario 4. These figures do not match exactly, partly because the second decade ASQ extends 20 years from the decision, while the projected demand represents an annual figure 15 years out.

Alternatives Allocating all Roadless Areas to Non-Development LUDs. As mentioned at the beginning of this section, the Ninth Circuit found the 1997 Tongass Forest Plan Revision Final EIS deficient because all of the alternatives considered in detail allocated some roadless areas to LUDs that allow development; the 1997 Final EIS did not include an alternative that allocated less undeveloped land to the development LUDs.

To remedy this deficiency, the Final EIS for the 2008 Tongass Forest Plan Amendment considers Alternative 1, which allocates no roadless areas to the LUDs that allow development, as shown in Chapter 2 of the EIS. In the interest of clarity, I point out that some activities that might be considered “development” may sometimes be allowed in many of the non-development LUDs. The most significant of these is the construction of a State highway or utility system connection between communities in Southeast Alaska, or between the region and the continental road system and power grid. Such development could be allowed in many “non-development” LUDs, including areas that are currently roadless. Such development is expected to be quite rare, and would require additional project-level NEPA analysis and decision-making before actual construction could begin.

The Forest Service received several comments from the public concerning the range of alternatives considered in the Draft EIS. The most frequent concern expressed was that the Draft EIS did not include an alternative with an ASQ lower than 50 MMBF. Several reviewers recommended such an alternative be included in the Final EIS, because they believe that timber harvest levels are likely to fall below that level.

As discussed in the section of this ROD on alternatives considered, and in Chapter 2 of the Final EIS, all alternatives displayed in all the EISs developed for the 1997 Forest Plan were reviewed for consideration in detail in the Draft and Final EIS for the 2008 Tongass Forest Plan Amendment. As displayed in Table 2 of this ROD, Alternative 1 of the 1996 Revised Supplement to the Draft EIS for the Revised Tongass Forest Plan was analyzed in detail in that EIS, and had an ASQ of zero. This alternative was also considered in detail in the 1997 Final EIS. This alternative was not considered in detail in the Draft or Final EIS for the 2008 Forest Plan Amendment for several reasons:

- The previous consideration in the 1996 and 1997 EISs was deemed adequate.
- The concern being addressed by alternatives with a low ASQ—avoiding development in roadless areas—is addressed by Alternative 1 of the 2008 Final EIS, because this alternative avoids timber harvest in roadless areas.
- Information from a variety of sources (e.g., mill capacity utilization reports and communications from operators) gave rise to concerns that the current timber industry in Southeast Alaska could not survive if an alternative were selected with an ASQ equal to or lower than current harvest levels.

Cumulative Effects of Disproportionate High-Volume Logging

The Court of Appeals for the Ninth Circuit found several deficiencies in the 1997 Final EIS for the Tongass Plan related to the cumulative effects of disproportionate high-volume logging (a practice sometimes called "highgrading") on non-federal land.[20] Specifically, the court found that the 1997 EIS failed adequately to consider such cumulative effects because the EIS did not include: (1) a catalog of past projects; (2) a discussion of how those projects (and differences between the projects) have harmed the environment; (3) a discussion of the connection between individual non-federal high-volume harvests and the prior environmental harm from those harvests; and (4) an assessment of the potential impacts of reasonably foreseeable continued highgrading in the future.

The court also found that a cumulative effects analysis in a new programmatic EIS is necessary for the Forest Service and the public to make a rational evaluation of the proposed action balancing the competing goals of timber harvest, environmental preservation, and recreational use in the Tongass.

Catalog of Past Projects on Non-Federal land. Because information about specific projects on non-federal land was unavailable in 1997, the cumulative effects analyses in the 1997 EIS assumed that all non-national forest land within the boundaries of the Tongass National Forest had no habitat value and therefore would not contribute to wildlife viability on the Tongass. In other words, non-federal land was analyzed as if it contained no vegetation whatsoever. In response to the court's concern regarding the lack of a catalog, the Forest Service worked with the State of Alaska and Sealaska Corporation, the regional Native corporation for Southeast Alaska, to develop a comprehensive catalog of each timber harvest project conducted on State land and Alaska Native corporation lands.

Appendix E of the Final EIS provides a catalog of past harvest by breaking down all past harvest in Southeast Alaska according to landowner category within each of 23 biogeographic provinces and identifying the acreage and decade(s) of harvest for each. In addition, the appendix summarizes the data provided by the State of Alaska regarding past harvest activities in Southeast Alaska permitted under the Alaska Forest Resources and Practices Act.

While Appendix E of the Final EIS complies with the court's direction to develop a catalog of past projects on non-federal land, this is only a small part of the analysis contained in the Final EIS of the potential cumulative effects of the disproportionate harvest of high-volume timber on non-federal land. For example, better mapping of current stand conditions on all land ownerships in Southeast Alaska has improved the analysis of effects of past timber harvest throughout the region. In addition, because complete information on stand types associated with early harvests was not documented or available, a method of estimating the proportion of different types in past harvests was developed and applied to all past harvest areas. The methodologies used to quantify the amounts and types of past harvest and project future harvests on both federal and non-federal lands are described in Appendix B of the Final EIS.

[20] While this ROD uses the term "highgrading" as it is used in the Ninth Circuit Court's opinion, it is a silvicultural term correctly defined as selective removal of the biggest and highest value trees from a stand. Over time, this can reduce the overall genetic quality of the stand.

The Biodiversity section of the Final EIS uses the Appendix E information along with geographic information system analyses and other information to describe in detail the total amount of past old-growth harvest on National Forest System (NFS) lands and non-NFS lands, and the amount within each of 23 biogeographic provinces that make up Southeast Alaska. In addition to the total amount of productive old-growth harvest, the amount of high-volume and large-tree old-growth harvest, the amount of harvest on karst terrain, and other descriptors are provided and discussed. In addition, projections are made in order to quantify future harvest levels for each of these categories and the effects of cumulative harvests are evaluated.

These analyses show that 92 percent of the original old growth still exists on NFS lands. When non-NFS lands are also considered, this percentage drops to 87 percent for all of Southeast Alaska. Similarly, 87 percent of the original high-volume old growth and 80 percent of the original large-tree old growth still exists on NFS lands, but 70 and 68 percent of these categories exist for all of Southeast Alaska, respectively.

Even if timber were harvested for 100 years at the maximum rate allowed under the amended Forest Plan, 83 percent of the original productive old growth, 79 percent of the original high-volume old growth, and 72 percent of the original large-tree old growth on NFS lands would still remain. If non-NFS lands are also considered, these percentages would decline to 76 percent, 70 percent, and 57 percent.

High-volume productive old growth currently makes up approximately 41 percent and large-tree old growth makes up 11 percent of the productive old growth on the Tongass. These two categories make up the same percentages within the reserves of the conservation strategy. Overall, and once standards and guidelines such as riparian and beach protection are applied, about 90 percent of the existing high-volume old-growth and 89 percent of the existing large-tree old growth would be protected under the amended Plan. This is a conservative estimate, based on the assumption that maximum harvest levels allowed under the ASQ are implemented over many decades.

As discussed in previous sections of this ROD, however, the duration of this decision is 10 to 15 years, not 100 years. The analyses described above also show that, if timber were harvested at the maximum level allowed by the amended Forest Plan for 15 years, 89 percent of the original productive old-growth forest would remain on the Tongass (97 percent of the existing old growth); as would 84 percent of the original high-volume old growth (97 percent of the existing high-volume old growth) and 77 percent of the original large-tree old growth (96 percent of the existing large-tree old growth).

This high level of protection for high-volume old growth is in part a direct result of the design criteria for the makeup of the reserves, which is just one way in which the 1997 Forest Plan was responsive to the disproportionate harvest levels of the past, including harvests on non-NFS lands. For example, Appendix K to the Forest Plan (1997 and 2008 Amendment), which establishes criteria for old-growth reserves, has specific target levels for high-volume old growth. Additionally, the adjustments to the small old-growth reserves and the expansion of other non-development LUDs included in this decision add about 149,000 acres to the reserve system relative to the 1997 Forest Plan, as amended. These acreages include 45,000 additional acres of productive old growth, 27,000 acres of which are high-volume old growth (59 percent), and 11,000 acres of which are large-tree old growth (25 percent).

Therefore, past timber harvest, including past disproportionate harvest of high-volume stands, has been considered in the design of old-growth reserves and in the development of the conservation strategy. Effects analyses for all resources were based on the environmentally conservative assumption that all scheduled suitable lands would be harvested at some point over the next 100-150 years. Because most of the Tongass lands suitable for timber harvest are undeveloped, it is reasonable to schedule higher-volume stands, higher in proportion to their existence, for the purpose of offsetting high infrastructure development costs. Once the infrastructure is in place, lesser volume stands can be accessed at a higher rate because the cost of access is less. Doing otherwise creates deficit timber sale projects needing supplemental funding to offset infrastructure costs. Appropriation legislation for the last several years has not allowed the offering of deficit timber sale projects nor provided funding levels necessary to offset initial entry costs.

Comparison of Alternatives

Wildlife Viability

Long-term viability for wildlife species has been extensively studied and analyzed, and is discussed in detail in the Final EIS (Chapter 3, Biodiversity and Wildlife sections and Appendix D). Panels of experts were formed to assess viability risks to key species that could result from each alternative considered in the 1997 Forest Plan Revision EIS. These ratings were transferred to the alternatives in the 2007 Draft EIS, based on the four alternatives that are similar between the two documents and similarities in the amount of timber harvest allowed. Based on this analysis, the alternatives fall roughly into three groups.

Compared to the other alternatives considered in detail, Alternatives 1, 2 and 3 provide the highest degree of assurance that the habitat needed for viable, well-distributed wildlife populations would be maintained, and that subsistence, recreational, and commercial uses of wildlife resources would be sustained. This is due largely to more non-development LUDs and refinements to small old-growth reserve boundaries that protect more high quality old-growth habitat, as compared to Alternative 5 (the 1997 Forest Plan).

Alternatives 4 and 7 provide the least assurance that the habitat needed for long-term viability of all wildlife species would be maintained because more acres are in development LUDs and there would be poorer distribution of high quality old-growth reserves in Alternative 4, and none in Alternative 7. The U.S. Fish and Wildlife Service, in their comments on the Draft EIS, expressed concerns that these alternatives would fail to ensure viable, well-distributed populations and recommended these alternatives be eliminated from further consideration.

Alternatives 5 and 6 provide a moderate to very high degree of assurance that, even if development occurs at maximum allowable levels for 100 years, there would still be sufficient habitat to support long-term viability of wildlife species because there would be a good to very good distribution of high quality old-growth reserves over the long term. Alternative 6 includes improvements to the small old-growth reserve system that Alternative 5 does not have, and includes more total acreage in reserves than Alternative 5. Alternative 6 as displayed in the Final EIS would apply the revised version of the goshawk nest standards and guidelines and the new forest-wide legacy standard and guideline. I want a Forest Plan that, in conjunction with all the other multiple-use goals and objectives, has a relatively low level of risk—or conversely, gives me good assurance that the habitat needed to sustain viable populations of wildlife would be maintained over the long term. As explained in greater detail in the section of this ROD regarding wildlife habitat and biodiversity, Alternative 6—with the changes specified in this ROD--provides this assurance and retains the major components of the original conservation strategy. Alternatives 4 and 7 may not provide adequate assurance of meeting viability requirements.

Socioeconomic Considerations

As was true in 1997, maintaining options for a variety of social and economic uses of the Tongass is another key factor in my decision. These social and economic uses range from continuing a timber harvest program that provides a sustainable supply of timber and other timber products to providing for subsistence opportunities and unspoiled settings for recreation and tourism. It is partly a matter of finding a balance, within a multiple-use context, of the many public uses and demands on forest resources, and partly not foreclosing options for the future to respond to changes in public needs, economic conditions, or new technologies as such changes develop.

Alternatives 1 and 2 would not allow sufficient timber volume to meet the projected market demand under the scenario considered most likely to occur over the next 15 years, nor would they allow the development of an integrated timber industry. (See the market demand section of this ROD for a discussion of the scenarios depicted in the most recent study of demand for timber from the Tongass.)

Only Alternatives 4 and 7 could provide sufficient timber volume to meet the high integrated industry scenario, but with more trade-offs for wildlife habitat (described above), recreation opportunities and scenic quality, due to allocating 28 percent and 30 percent of the Tongass to moderate and intensive development LUDs, respectively.

Alternatives 3, 4, 5, 6, and 7 could all provide sufficient timber volume to meet the medium integrated scenario, although Alternative 3 could not provide sufficient economic volume. While Alternative 3 allocates 18 percent of the Tongass to moderate and intensive development LUDs, less than the 22 percent in Alternative 5 and 21 percent in Alternative 6, it does not provide enough opportunity for growth of an integrated timber industry over the next 10 to 15 years, which limits the potential socioeconomic development of many rural communities within the Tongass National Forest. Recreation opportunities and scenic quality are very similar between Alternatives 5 and 6. Alternative 6 changes the wildlife habitat standards and guidelines to reduce their economic impact, which leads me to conclude Alternative 6 best balances competing values and uses of the Tongass National Forest.

Present net value calculated for each alternative represents one efficiency measure for those costs and benefits that can be assigned monetary values, in this case timber, recreation and tourism and program management costs. Alternative 1 is estimated to have the highest present net value and Alternatives 4 and 7 the lowest, largely due to the high costs of operating timber programs in Alaska. The estimate of present net value for Alternative 6 is in the middle of the range of all the present net values for the seven alternatives considered. Given the failure of present net value to consider qualitative factors critical to accurately predicting net public benefits, and the ability of Alternative 6 to balance many competing values and uses of the Tongass National Forest, I find that Alternative 6 currently provides the best strategy for maximizing net public benefits.

Roadless Areas

Alternative 1 does not allocate any inventoried roadless acres to development LUDs, and has the fewest acres suitable for timber harvest. Alternatives 4 and 7 are at the other end of the spectrum, with the greatest amounts of the existing roadless areas allocated to moderate and intensive development LUDs and suitable for timber harvest.

Alternatives 2, 3, 6, and 5 show gradual increases in the acreage of existing roadless areas allocated to moderate and intensive development LUDs, with Alternative 6 slightly less than Alternative 5. With the Timber Sale Program Adaptive Management Strategy, I am confident that the highest value roadless areas within the suitable land base will be protected until needed to meet demonstrated growth and integration in the timber industry. Alternative 6 best provides the flexibility and balance to meet the competing demands for growth and for the protection of roadless character, recreation, and other socioeconomic values associated with roadless areas.

Other Resources

Alternatives 1, 2, 3, 5 and 6 are better than alternatives 4 and 7 in maintaining scenic quality and undisturbed settings, factors important to the continued expansion of the recreation and tourism industries, and to most Southeast Alaska communities.

The abundance and distribution of the majority of subsistence resources (fish and marine invertebrates) would not be affected by any alternative. The analysis continues to suggest that deer habitat capabilities in the areas of the Tongass with heavier timber harvest may not be adequate to sustain current and future deer harvest levels under any alternative, and that increased competition for deer harvest may cause a significant possibility of a significant restriction in the future.

This possibility of future restrictions resulting from changes in abundance and distribution of deer and increased competition would be lower for Alternatives 1, 2 and 3 and higher for Alternatives 4 and 7 compared with Alternative 5 (the 1997 Forest Plan, as amended). Alternative 6 is the same as Alternative 5 because similar amounts of acres are proposed for timber harvest.

Compared to Alternative 5, all other alternatives expand the Mineral LUD overlay by approximately 80,000 acres. None of the alternatives includes any changes to the management of mineral activities. No land ownership adjustments are proposed under any alternative and all alternatives, except Alternative 5, include recommending the Experimental Forest at Young Bay be replaced by a larger, more accessible Experimental Forest at Cowee and Davies Creek and that the Geologic Special Interest Areas be expanded by about 47,000 acres.

Alternative 1, the "environmentally preferable" alternative, would result in the least adverse effects to the physical and biological environment. With timber harvest scheduled only along the existing road system and no development in roadless areas, it has the least effects of the alternatives considered. Accordingly, in comparison with other alternatives, it tends always to rate highest when levels of resource protection are a consideration. Conversely, when considering timber-related employment and community dependence on such employment; infrastructure development and new road access; or rural development in a multiple-use context, Alternative 1 generally ranks lowest. Therefore, I conclude that it does not provide an acceptable balance between the competing multiple use demands for environmental protection and human uses of the natural resources of the Tongass National Forest. For the same reasons, it also does not meet the objectives of ecological, economic, and social sustainability.

Conclusion

Given the many social and economic trade-offs inherent in national forest management, I find that Alternative 6 best balances the many interrelated environmental, social, and economic issues that arise when managing for multiple uses.

Other Considerations

In addition to responding to the decision by the Ninth Circuit Court of Appeals and the key issues described above, my decision is based on consideration of several other topics, including invasive species, management of young-growth forest stands, climate change, ecosystem services, transportation and utility corridors, cooperation with the State of Alaska, public input, areas of special interest, and the use of the best available science.

Invasive Species

The 1997 Forest Plan did not include the term *invasive species*. Nationally and regionally, the Forest Service is giving high priority to eliminating or preventing adverse impacts caused by invasive species. The amended Forest Plan includes new objectives and standards and guidelines that will enable the Tongass National Forest to carry out these relatively new national and regional priorities on the Tongass. As is true in other program areas, the extent to which these objectives can be met is dependent in large part on factors out of the control of the Forest Service, such as congressional funding allocations.

Management of Young-Growth Forest Stands

The management of young-growth forest stands is becoming more important as young trees located in previously harvested areas mature, and as interest grows in transitioning the timber industry in Southeast Alaska from one based on the harvest of old-growth forest stands to one based on the harvest of young growth. Young-growth forest stands are those that grow after the trees in an area have been removed by timber harvest activities or a natural disturbance event such as a landslide or windstorm. A substantial amount of new information has become available regarding the management of young-growth forests since the 1997 Forest Plan was adopted. For example, forbs and shrub populations are more extensive in thinned young-growth stands than was assumed in previous forest planning efforts. This information is relevant for the analysis of the effects of timber harvest on species like the Sitka black-tailed deer that feed on forbs and shrubs. Management practices of young-growth forest stands, such as thinning, can substantially improve the forage for deer, and also promote better growth of the remaining trees for future timber harvest. Precommercial thinning involves cutting most of the small trees that naturally grow back in areas where the old-growth trees have been removed, usually about 15 to 25 years after the initial removal. When thinning is done at this stage, the young-growth trees removed are so small that that they usually have no commercial value, so it must be paid for by appropriated funds. Similarly, thinning of young-growth stands that are 50 to 70 years old can yield commercially marketable trees—hence the name "commercial thinning"--while also improving forage for wildlife and higher timber yields in the future. Many organizations have encouraged the Forest Service to transition the timber program on the Tongass from one based on the harvest of old-growth forest to one that harvests young-growth stands. Such a transition would enhance the protection of old-growth forest habitat.

For all of these reasons, I support the transition of the Tongass timber program to one based more on the harvest of young-growth stands. The amended Forest Plan has been carefully reviewed to ensure that it contains no provisions that might impede such a transition. Young growth could potentially comprise a substantial portion of the Tongass timber program in as little as three decades, with initial young-growth operations beginning in earnest by the end of the current planning cycle. The ultimate success of this effort, however, will depend on several factors, including investments by the timber industry in milling equipment designed for smaller young-growth trees, integration of the industry to effectively process all products harvested from the Forest, and funding decisions made by Congress.

Climate Change

Interest in climate change, and knowledge of this issue, have grown enormously over the last decade. The two broad questions relevant to the decision on the 2008 Forest Plan Amendment are the extent to which climate change might affect the natural resources of the Tongass National Forest and the uses of those resources, and the extent to which management of the Tongass could affect climate change.

As discussed in Chapter 3 of the Final EIS, the effects of climate change on the natural resources of the Tongass are highly uncertain, especially over the long run, and likely to be small, especially over the next 10 to 15 years. While there is general agreement among scientists that the climate is warming, there is considerable uncertainty concerning the exact effects of climate change on the forests of Southeast Alaska and how best to deal with possible changes to the many resources on the Tongass. There is a risk that climate change may result in increased blowdown, increased tree mortality from insects and disease, increased fire frequency and severity, adverse effects on air quality, changes to vegetation, streams, fish and wildlife habitat, and subsistence and recreational uses of the National Forest. However, there is considerable uncertainty concerning specific predictions of how the climate may change, and even more uncertainty regarding the effects of climate change on the resources of the Tongass National Forest.

Consequently, it is important for the Tongass to stay abreast of the evolving scientific information related to the effects of climate change. However, the state of current knowledge and the uncertainty about specific effects of climate change leads me to conclude that the best course of action today is continued management of the Tongass for resiliency in the face of uncertain but anticipated change. This will be done primarily by management of the Tongass as a mostly intact ecosystem with a robust monitoring plan that will allow for adaptive management intervention if and when effects of climate change are more certain.

The same is true regarding effects on climate change of the alternatives analyzed in the Final EIS. For example, as described in the Climate and Air section of Chapter 3, the science regarding the effects of timber harvest on carbon sequestration is uncertain. Some studies suggest that timber harvest may increase the release of carbon to the atmosphere, which would tend to increase greenhouse gasses and global warming. Others indicate that timber harvest may increase the amount of carbon sequestered from the atmosphere. In either case, the effects are likely to be small, especially compared to other routine human activities. Accordingly, information on climate change is not essential to a reasoned choice among the alternatives displayed in the Final EIS.

For these reasons, the issue of climate change has played a limited, but important role in this decision in the context of monitoring. The Forest Service will continue to monitor potential effects of climate change through existing monitoring programs and through the Monitoring and Evaluation Plan. Existing monitoring programs include our Regional forest health program that monitors forest health changes related to insects, disease, pathogens and windthrow across Region 10, and the long-term forest inventory system. In addition, the Forest Plan's monitoring and evaluation provisions have been updated to address the effects of all change, including climate change I believe these efforts will detect any significant effects of climate change on the Tongass. If such changes are detected, they will be addressed through existing planning procedures to determine whether changes in management of the Forest are warranted.

Ecosystem Services

Ecosystem services are those services and benefits provided by healthy ecosystems. They can be broadly defined to include consumptive uses, such as logging, fishing, and hunting, as well as other benefits associated with forests such as watershed services, soil stabilization and erosion control, improved air quality, climate regulation, carbon sequestration, and biological diversity. Ecosystem services are a topic of growing interest within the Forest Service, its partners and stakeholder groups.

Some members of the public have expressed concerns that ecosystem service values are not adequately considered in decision-making processes because they are not valued on a par with goods and services that are traded in commercial markets. The Final EIS discusses different attempts to measure the value of ecosystem services. While ecosystem services values on the Tongass are undoubtedly high, there is uncertainty about the accuracy of these estimates. It is also difficult to determine how the alternatives differ in the level of ecosystem services provided. The fact that the Final EIS does not assign a monetary value to ecosystem services does not lessen their importance in the decision-making process. In fact, a large proportion of the Final EIS is devoted to assessing impacts to the forest resources that cannot be readily expressed in monetary terms. This decision takes these values into consideration. As previously mentioned, the undeveloped nature of the Tongass National Forest, and the ecosystem services provided by the Forest, will be adequately protected by the Forest Plan. Even if timber harvest and road construction were conducted at maximum allowable levels under the Forest Plan for 100 years, at least 80 percent of the Tongass would still be in a roadless, undeveloped condition.

This Forest Plan Amendment also supports ongoing initiatives in Southeast Alaska to develop ecosystem services markets such as the Fuels for Schools program, thinning of young growth for wildlife habitat improvement, and implementation of practices and technologies to reduce the carbon 'footprint' of Forest Service operations.

Transportation and Utility System Corridors

The Transportation and Utility System (TUS) LUD was originally developed as part of the 1997 Plan to:

- Acknowledge the potential need for major highways or utility systems connecting communities in Southeast Alaska with each other, and connecting the region to the continental highway system and power grid.
- Identify likely locations for such connections.
- Facilitate construction of them.

The Forest Plan does not, however, approve any of these projects. As with any other proposed site-specific activity, construction of a TUS requires further project-level NEPA analysis and decision-making. During that process, all reasonable alternative routes must be considered, even those that may not be foreseeable at the programmatic, Forest Plan stage. Consequently, the objectives of the TUS LUD can be met without trying to identify on the LUD map every reasonable alternative route for every potential highway or utility system.

During the development of the EIS for the 2008 Forest Plan Amendment, State agencies and members of the public expressed concerns that not all potential TUS corridors were on the Forest Plan LUD map. Specifically, the Alaska Department of Transportation and Public Facilities (ADOT&PF) advised that several potential TUS routes identified in the Department's Southeast Alaska Transportation Plan were not included in the Draft EIS map. In response to these concerns, the Forest Service added a potential utility route for the community of Pelican to the LUD map in the Final EIS, and made other minor changes. In addition, the Plan's management direction for the TUS LUD has been clarified to improve its implementation, and to note that not all reasonable alternative routes for all potential TUS connections are—or can be--identified on the map. The Forest Service also will retain the information provided by ADOT&PF regarding alternative TUS routes in the planning record, to ensure this information will be available for any future land management decisions.

Cooperation with the State of Alaska

The Forest Service and the State of Alaska signed a Memorandum of Understanding (MOU) (January 28, 2006) to include the State as a cooperating agency in the development of the 2008 Forest Plan Amendment. Under this MOU, the State has participated extensively throughout the planning process for the 2008 Forest Plan. This cooperative effort has been essential in clarifying and resolving many land management issues. Future cooperation is addressed under the implementation section of this ROD.

Public Input

As explained in Chapter 1 of the Final EIS, the 2008 Tongass Forest Plan Amendment is based in part on public input gathered over the course of many years during previous planning efforts, including the development of the 1997 Forest Plan, the 2003 Supplemental EIS, the National Roadless Rule and project-level NEPA analyses. Additional public input for the 2008 Amendment to the Tongass Forest Plan began in January 2006 when the Forest created a website specific to the amendment (*www.tongass-fpadjust.net*) and requested input on the amendment process. The Notice of Intent to prepare the EIS continued the process of gathering public input when it was published in the *Federal Register* in March 2006. Appendix A of the Final EIS summarizes the public input process that led to the development of the significant issues.

The Draft EIS was released for public comment in January, 2007. Twenty-five public meetings were held. These meetings included 23 meetings in communities located throughout Southeast Alaska, a meeting in Anchorage, and an electronic public meeting held on the internet. These meetings included both an open house and a hearing. A total of 204 people provided formal testimony at these hearings.

The 90-day public comment period was scheduled to end in mid-April but was extended an additional 18 days because of bad weather in Southeast Alaska and to give people more time to comment on the changes made to small old-growth reserves. Approximately 84,500 comments were received during the 108-day public comment period. Approximately 98 percent of the responses were form letters. Comments were received from all 50 states and 89 other countries. This reflects the importance of the Tongass at the national and international level.

All comments were carefully reviewed, coded, and consolidated into logical comment summaries. Responses were developed to each comment summary and revisions made to the analysis or Forest Plan as appropriate. These comment summaries and responses can be found in Appendix H of the Final EIS.

Review of the public comments resulted in Alternative 1 being modified between the Draft and Final EIS, with all roadless areas and other high interest areas, such as Kuiu Island, being removed from the suitable timber land base. The results of the public involvement and comment process led to a number of other improvements, clarifications and updates between the Draft and Final EIS.

Tribal governments and Alaska Native corporations were also consulted throughout the planning process. They participated in the hearings described above and their comments are included in the summaries developed for Appendix H.

There have been numerous collaborative meetings and discussions held between groups with an interest in the Tongass. The Tongass Futures Roundtable, a group of 35 diverse stakeholders, organized many of these discussions with the intent of finding common ground on Tongass issues. These discussions continue and I am encouraged by the willingness of participants to work towards solutions that will benefit all of Southeast Alaska.

Finally, during the course of the development of the 2008 Forest Plan Amendment, the Forest Service has had thousands of informal contacts with people interested in the Amendment. The Forest Service approach has been thoroughly open and transparent. I am proud of the extent to which the Forest Service has involved the public in this process.

The Use of Science in the Planning Process

This Forest Plan Amendment builds upon the work previously done to revise and amend the Forest Plan. The management direction in the 1997 Tongass Forest Plan was the result of significant collaborative efforts throughout Southeast Alaska, the State, and across the nation. The 1997 Plan was developed collaboratively with other Federal and State natural resource management agencies, including the National Marine Fisheries Service, the Alaska Department of Fish and Game, the U.S. Fish and Wildlife Service, the Environmental Protection Agency, and the Forest Service Pacific Northwest Research Station. Representatives of the last three agencies were full members of the 1997 Tongass Forest Plan Revision interdisciplinary planning team. The process for developing the 1997 Forest Plan included peer reviews of the conservation strategy and review by panels of wildlife experts to ensure the Plan would be scientifically credible and resource sustainable.

The conservation strategy was the subject of a technical interagency workshop held in April 2006, which was designed to review and evaluate the conservation strategy in light of new science developed since the 1997 Plan. The workshop brought together scientists from a variety of organizations, including the Forest Service, the State of Alaska, other agencies, universities, and others, along with Tongass land managers, to report on and discuss current research relative to the conservation strategy, as well as experiences over the past 10 years relative to its implementation. The new science discussed at the workshop was fully considered throughout the planning process and in the modifications to the Plan.

The development of the EIS and the amended Forest Plan has been based on consideration of the best available science throughout the planning process. This has occurred by comprehensively reviewing available scientific research and other information relevant to the resource areas addressed. In addition, the specific modeling and analysis methods used were documented in Appendix B of the Final EIS or within other appendices or individual resource sections. Scientific sources relied on were cited, responsible opposing views were discussed, incomplete and unavailable information was acknowledged, and scientific uncertainty and risk was addressed in relevant portions of the Final EIS.

The amended Forest Plan provides for the sustainability of the resources of the Tongass National Forest, while directing the coordination and management of multiple uses of national forest land resources in cooperation with the State of Alaska, such as outdoor recreation, timber, mining, wildlife, fish, watershed, and wilderness. Recognizing that conditions on the Tongass National Forest do not remain static, that new information is constantly surfacing, and that considerable scientific uncertainty is associated with many conclusions regarding resource effects, the amended Forest Plan embraces an adaptive management approach. The Timber Sale Adaptive Management Strategy is a good example of this approach.

The Tongass National Forest worked closely with the Pacific Northwest Research Station to ensure consideration of the best available science throughout the process of amending the Tongass Forest Plan. The Station provided various science products to the Tongass Planning Team. Station scientists conducted four advisory science consultations on the topics of timber demand analysis, ecosystem services, and the use of deer models. Several Station scientists participated in the 2006 conservation strategy review workshop to examine new science information relating to the conservation strategy, and to identify additional information needs for the Tongass Plan Amendment. The Station produced a revised timber demand analysis which was published in July of 2006 (Brackley et al 2006). The Tongass Planning Team utilized the information from the new report, science consultations and the conservation strategy workshop in developing the Draft EIS.

Following the release of the Draft EIS, the Pacific Northwest Research Station conducted six science reviews to determine if relevant science information was considered and reasonably interpreted with consequences, uncertainties and risks appropriately identified. Informal science reviews were conducted on timber demand analysis, vegetation mapping, young-growth management, carbon sequestration and climate change, and ecosystem services. A more formal review was conducted on the elements of the conservation strategy dealing with the Queen Charlotte goshawk, American marten, Sitka black-tail deer, northern flying squirrel and endemic mammals. Station scientists were asked by the Alaska Forest Association (AFA) to describe more fully the timber demand study. In response, the scientists met with AFA and held a workshop to explain their methodology. As additional follow up, Station scientists also crafted the addendum to the Brackley et al. study of timber demand to provide additional details and clarification.

The Pacific Northwest Research Station provided input to Appendix D of the Final EIS, which deals with the science background, description of changes, assumptions and rationale for the old-growth conservation strategy, wildlife standards and guidelines, and wildlife viability components of the Forest Plan. The Station also provided input to Appendix G of the Final EIS, which describes how the Station’s market demand projections are used in timber sale planning. The Tongass Planning Team considered all the information from the science reviews, the timber demand addendum, and comments on Appendix D in compiling the Final EIS and ROD. A reconciliation table was developed to document how the science review input was considered in development of the Final EIS. The planners also met directly with Station representatives in July of 2007 to discuss the reconciliation of comments and seek additional feedback. The administrative record includes all science advisory consultation and science review comments provided by the Station, as well as the reconciliation demonstrating how the comments and information were used to inform the Final EIS and ROD.

Based on the level of rigor employed in reviewing available science and in incorporating and documenting this information throughout the planning process, in addition to the involvement of the Pacific Northwest Research Station at every step of the planning process, I am confident that the Final EIS and this ROD thoroughly consider and use the best available science.

Potential Land Adjustments

Appendix C of the Final EIS has been updated regarding new developments relating to potential land adjustments that could affect the implementation of the Forest Plan. Conceptual proposals from the Trust Land Office, representing the Alaska Mental Health Trust Authority, and Shee Atika Corporation are discussed in Appendix C. Additionally, proposed legislation introduced since the Draft EIS was published warrants some discussion here.

Two bills have been introduced in the U.S. House of Representatives that may affect lands within the Tongass National Forest, H.R. 3350, the Alaska Native Veterans Land Allotment Act and H.R. 3560, the Southeast Alaska Native Land Entitlement Finalization Act. Although a hearing was held by the House Natural Resources Committee in November, 2007 regarding these proposed bills, at this time no additional hearings or committee assignments have been identified and it is not clear whether these proposals will move further through the legislative process. Based on their current status, addressing the effects of these proposals relative to this Forest Plan decision is premature given the speculative nature of the prospects for legislative enactment. If at a later date one or both of these proposals become law, an analysis of the effects will be necessary to determine if a revision or amendment of the Forest Plan is warranted.

Land adjustments have been and will continue to be important considerations as the new Forest Plan is implemented. To continue to meet the conservation strategy and timber management goals and objectives of this Forest Plan decision, major discretionary land adjustment proposals will be considered if the proposed exchange of lands maintains the conservation strategy, ensures public access for subsistence uses, and at least a portion of the timber volume from the lands conveyed from the Tongass National Forest contributes to the timber manufacturing industry in Southeast Alaska.

National Policy Considerations

The Forest Plan reflects several aspects of national policy. Among the most important of these is the Forest Service Strategic Plan, developed under the Government Performance and Results Act of 1993.

In July 2007, the Forest Service completed a Strategic Plan for Fiscal Years 2007-2012, which provides direction to guide the entire agency in delivering its mission. Forest Service programs and budgets are aligned with the goals and objectives in this Strategic Plan which supplements the USDA Strategic Plan for Fiscal Years 2005-2010. Managing the Nation's forests and grasslands requires the complex integration of several levels of planning and cooperation with State and local planning efforts. These levels are defined below.

- *Strategic planning* takes place at the highest level and identifies strategic priorities for the agency that are implemented over a period of time through annual agency budgets. The strategic priorities are based on national assessments of natural resources and are responsive to social and political trends.
- *Business planning* by national programs, regions, research stations, and the Northeastern Area translates the broad strategic direction into the regionally specific work that contributes to the agency's mission.
- *Unit planning* (e.g., land and resource management plans for national forests and grasslands) provides an inventory of resources and their present conditions on a particular management unit. This inventory, coupled with the desired future condition for the resources, is the basis for annual work planning and budgeting.
- *Annual work planning* identifies the projects that all units propose for funding within a fiscal year. This level of planning involves the final application of strategic direction into a unit's annual budget to move its resources toward its desired future condition.

In addition, monitoring is essential to track resource conditions and human activities over time to effectively manage the Nation's forests and grasslands.

This amendment to the Tongass Forest Plan fulfills the unit planning level described above, and implementation will occur through the annual work planning level. In addition, the monitoring plan has been refined as the essential quality control mechanism that facilitates learning from Plan implementation.

I find the amended Tongass Forest Plan to be not only consistent, but strongly supportive of the goals in the agency-wide Forest Service Strategic Plan, as follows:

1. This decision continues to provide a balance between land stewardship services and meeting public demands for various uses of the Tongass National Forest. The updates and refinements in the Forest Plan multiple-use goals and objectives and management prescriptions include direction for rare plants, sacred sites, invasive species, and young growth management that will continue to restore, sustain and enhance the Forest's ecosystems and related services.
2. By keeping the ASQ at a level able to meet the possible future demands of an integrated industry, the amended Forest Plan helps maintain or create processing capacity and infrastructure in local communities. With the Timber Sale Program Adaptive Management

Strategy, I am confident that higher value roadless areas will remain intact unless timber harvest levels increase beyond 150 MMBF long enough to implement Phase 3 of the Strategy.

3. While open space is not the same issue in Southeast Alaska as it is in other parts of the country, partnerships with the State, Tribes, Native Corporations, and local communities will continue to contribute to responsible land management across all lands.
4. Continued use of the recreation opportunity spectrum to help identify and quantify different types of recreation settings on the Tongass National Forest will assure a mix of the highest quality outdoor opportunities and experiences. The sense of vastness, wildness and solitude will remain, with over three-quarters of the Tongass in natural or undeveloped LUDs, and opportunities for other users' desires to have developed and easy access will remain or may be increased in the moderate and intensive development LUDs.
5. Maintaining basic management capabilities relates to daily operations and accountability on the Forest, including continuing to cooperate with other Federal, State, Tribes, Native Corporations, local governments and private-sector partners. The objectives in the amended Forest Plan continue to emphasize opportunities for rural community and technical assistance.
6. While engaging Urban America may not seem directly applicable to Southeast Alaska, the Tongass leadership will continue to engage partners and educators in development and use of conservation education materials during implementation of the Forest Plan. One of the recreation and tourism objectives continues to emphasize projects that facilitate community use or community connections, and another forest plan standard and guideline is to identify opportunities and priorities for interpretation of heritage resources for public education and recreation. Direction in the amended Forest Plan continues to encourage traditional American values such as conservation ethic, appreciation of nature, national and community pride, and national and community well-being, including the stability of lifestyle and character.
7. To provide science-based applications, the amended Forest Plan continues the goal to seek out and promote research opportunities consistent with identified information needs described in Appendix B. Objectives for the nonwilderness national monument LUD continue to be to inventory, research, protect and interpret National Monument resources and make resource and research information about National Monuments available to other forest units where it may be beneficial.

Means to Avoid Environmental Harm

Mitigation Measures Adopted

Extensive measures to avoid or minimize environmental harm were adopted in the 1997 Forest Plan. Based on 10 years of experience in implementing and monitoring these measures, many of them have been updated in the 2008 Forest Plan Amendment, as previously discussed. These measures include forest-wide standards and guidelines, and additional standards and guidelines for each land use designation. At a minimum, these standards and guidelines meet all requirements of applicable laws, regulations, and State standards. Mitigation measures are an integral part of the standards and guidelines. Singularly and collectively, they avoid, rectify, reduce, or eliminate potential adverse environmental impacts of forest management activities. Some more significant mitigation measures are the beach fringe and riparian buffer zones, and the network of old-growth reserves. Based on the analysis in the Final EIS, including the response to comments contained in Appendix H, I conclude that all practicable means to avoid or minimize environmental harm from the amended Forest Plan have been adopted.

Mitigation Measures Not Adopted

The State of Alaska recommended changes to a standard regarding protection of important brown bear foraging sites adjacent to salmon streams. Since 1997, this standard has required project-level planning teams to consult with the State to determine where such foraging sites exist, and where buffers of approximately 500 feet from the stream should be adopted, within which no timber harvest is allowed. The State recommended this be modified to mandate buffers of at least 500 feet on all anadromous streams. This change has not been adopted because brown bear populations are healthy, the analysis contained in the Final EIS indicates they will remain so, and monitoring information suggests the current standard is adequate. In addition, other standards and guidelines offer protection related to brown bear foraging sites. For example, the beach and estuary fringe standard and guideline requires no-harvest buffers 1,000 feet inland from beach vegetation. When applied on the ground, other existing standards often result in stream buffers of 500 feet in the lower reaches of salmon streams. For these reasons, I conclude that protection of brown bear foraging sites can continue to be ensured at the project level without additional requirements being added to the Forest Plan.

The U.S. Fish and Wildlife Service recommended that goshawk nest buffers be increased from 100 acres to 500 acres of productive old-growth habitat to protect active and alternate nest sites and post-fledging habitat from timber harvest. This measure was not adopted because the Service's recent decision not to list the goshawk as a threatened or endangered species under the Endangered Species Act suggests that such action is not essential, and because the analysis contained in the Final EIS indicates that nest buffers, in addition to the other protective measures included in the Forest Plan, will provide adequate habitat for nesting and fledgling goshawks.

Additional details on proposed changes to the Forest Plan, and the reasons why such proposals were not adopted, are contained in Appendix H of the Final EIS.

Monitoring and Evaluation

The Forest Plan includes a monitoring and evaluation plan to continually assess the effectiveness of the Forest Plan standards and guidelines. Monitoring results will be used to evaluate the assumptions used in developing the Forest Plan, and may be the basis for amendments or revisions, just as the information from the monitoring conducted since 1997 helped form the basis for this Amendment. The Forest Plan may be amended at any time if changes to the standards and guidelines are needed. Monitoring will also ensure that both forest-wide and land use designation standards and guidelines are being correctly applied. The monitoring program will include monitoring of timber harvest levels under the Timber Program Adaptive Management Strategy to determine if and when the timber program can move from one phase of the Strategy to another.[21]

In addition to the Forest Service, nearly all other State and Federal natural resource agencies, the academic community, and numerous organizations and individuals want to know more about the social, economic and ecological uses and values, including ecosystem services values, of the Tongass National Forest and the environment in which it is located. I believe there are many opportunities to better align and coordinate the interests, resources, and efforts of these groups in monitoring and evaluating the implementation of the Forest Plan. As previously mentioned, details of the monitoring program such as data gathering protocols will continue to be developed in consultation with all interested State and Federal agencies.

Findings Related to Other Requirements

The Forest Service manages the Tongass National Forest in conformance with many Federal laws and regulations. In this section we consider each of the major laws involved in this programmatic-level decision.

[21] All scheduled timber harvest in a fiscal year will count toward the level needed to move the timber sale program to a higher phase.

National Environmental Policy Act

NEPA requires that Federal agencies prepare detailed statements on proposed actions that significantly affect the quality of the human environment. NEPA's requirement is designed to serve two major functions:

- To provide decision-makers with a detailed accounting of the likely environmental effects of proposed actions prior to adoption.
- To inform the public of, and allow comment on, such efforts.

The Forest Service has developed, gathered, and reviewed an enormous amount of information regarding the potential effects of each of the alternatives considered in the Final EIS. This information expands and refines the data, analyses, and public input described in the NEPA documents associated with the 1997 Forest Plan, including the 1989 Analysis of the Management Situation (which has been updated as part of the 2008 Forest Plan Amendment and is contained in the planning record); the draft, supplemental, and final EISs leading to the 1997 ROD; documents associated with the 2003 Supplemental EIS; and the Draft and Final EISs for the 2008 Tongass Forest Plan Amendment. My decision also considers the vast array of public input, including public meetings, comments from the internet website, and comments received during the 108-day comment period on the Draft EIS.

All substantive comments, written and oral, made on the 2007 Draft EIS have been summarized and responded to in Appendix H of the Final EIS. During the course of this effort, this public involvement has lead to substantial changes in the analysis and the alternatives.

I find the environmental analysis and public involvement process the Final EIS is based on complies with each of the major elements of the requirements set forth by the CEQ regulations for implementing NEPA (40 CFR 1500-1508). My conclusion is supported by the following findings.

First, the Final EIS considered a broad range of reasonable alternatives. The seven alternatives considered in detail in the Final EIS represent only part of the total number of alternatives considered over the course of the analysis. As described above in the "Alternatives Considered" section, 39 alternatives from previous EISs were considered before selecting the seven analyzed in detail in the Draft and Final EIS. These seven alternatives presented in the Final EIS encompass a broad range of response to issues, including a timber suitable land base ranging from 0.3 to 1.2 million acres and an average annual first-decade ASQ from 49 to 421 MMBF.

Second, the Final EIS reflects consideration of cumulative effects of the alternatives by evaluating past, present, and reasonably foreseeable future actions in the planning area including Federal, State, Tribal and private lands. The environmental effects analysis estimates the potential effects of timber activities and timber-associated activities, such as road construction, for 100 years. The analysis of effects to wildlife was based on the assumption that these activities would take place at their maximum allowable levels each year for 100 years, an extremely conservative assumption. This analysis considers changes to vegetation both temporally and spatially (Final EIS Appendix D). Moreover, although non-federal lands are outside the scope of this decision, effects from their management have been thoroughly considered in the Final EIS.

Third, the Final EIS makes use of the best available information. The geographic information system database, constructed during the development of the 1997 Forest Plan, has been thoroughly updated, and was used to evaluate complex spatial effects resulting from implementation of the alternatives, such as maintenance of connectivity corridors for wildlife and how visual condition could change over time. The best available science was used to help estimate environmental consequences, as evidenced from the extensive reference section of the Final EIS (Chapter 6), the multiple appendices that document methods or other technical information, and the involvement of other organizations as described in the section of this ROD dealing with the use of science in the planning process. Uncertainties connected with environmental impacts and market demand have been acknowledged and addressed through the Timber Sale Program Adaptive Management

Strategy. A linear optimization model was used to estimate the long-term flow of timber from the planning area. All of these tools, taken together, constitute use of the best available information.

The decision here does not authorize timber sales or any other specific activity on the Tongass National Forest. Site-specific decisions will be made on projects in compliance with NEPA, the Endangered Species Act, and other environmental laws following applicable public involvement and appeal procedures.

National Forest Management Act

The National Forest Management Act and implementing regulations specify a number of requirements that guide Forest Service planning. The Forest Plan complies with each of these management requirements, as explained in this ROD and accompanying Final EIS and appendices. Certain requirements that received heightened public attention are discussed in further detail below and in other sections of this ROD.

Diversity and Viability Provisions for Fish and Wildlife

As described in detail in the section of this ROD on protecting wildlife habitat and biodiversity, after considering the statute, regulation, case law, and examination of the record, I find that this decision satisfies the requirements of the law because it will provide an amount and distribution of habitat adequate to maintain viable populations of vertebrate species in the planning area and will maintain the diversity of plant and animal communities. I base my determination on the evidence in the planning record, as summarized in the above section of this ROD.

Sensitive Species

A Forest Plan-level Biological Evaluation was completed for the 24 species/subspecies (4 wildlife, 2 fish and 17 plant species/subspecies) currently listed in the Alaska Region's sensitive species list that are known or are suspected to occur on the Tongass National Forest. For some species, individuals or their habitats may be impacted by the selected alternative, but the impacts are not expected to contribute to a trend toward Federal listing or cause a loss of viability to the population or species.

Endangered Species Act

There are no terrestrial species on the Tongass National Forest that are listed as threatened or endangered under the Endangered Species Act. Threatened and endangered species that may be affected by future projects, as discussed in the updated Biological Assessment, are limited to marine species (mammals and fish). Consultation requirements for these species under Section 7 of the Act were met with the U.S. Fish and Wildlife Service and the National Marine Fisheries Service.

Magnuson-Stevens Fishery Conservation and Management Act

Section 305(b)(2) of the Magnuson-Stevens Fishery Conservation and Management Act states that all Federal agencies must consult the National Marine Fisheries Service for actions or proposed actions that may adversely affect essential fish habitat. The Act promotes the protection of essential fish habitat through project review, assessment, and mitigation of activities that may adversely affect these habitats. The Forest Plan itself, including this amendment, does not authorize any specific project or actions and therefore does not affect essential fish habitat. Future project activities designed to implement the amended Forest Plan that may adversely affect essential fish habitat will go through consultation per the Act. The National Marine Fisheries Service was an important contributor in the development of the 1997 Forest Plan, participated in informal consultation and review of this amendment effort, and continues to be involved in the implementation and monitoring of projects and actions implementing the plan.

Tongass Timber Reform Act

The Tongass National Forest will continue to be managed in compliance with Section 101 of the TTRA, which states in part that the Secretary of Agriculture "…shall, to the extent consistent with providing for the multiple use and sustained yield of all renewable forest resources, seek to provide a supply of timber from the Tongass National Forest which (1) meets the annual market demand for timber from such forest and (2) meets the market demand from such forest for each planning cycle."

As discussed in detail in the section on market demand, the Forest Service has adopted an adaptive management approach to meeting these requirements. The requirement dealing with annual market demand is met through implementation of the Morse methodology, which estimates the volume of timber to be offered annually. The TTRA requirement regarding market demand for each planning cycle is met by adopting the selected alternative as described in the Final EIS and this ROD, and by a series of annual applications of the Morse methodology.

Coastal Zone Management Act

Under the Coastal Zone Management Act (CZMA), Federal agency activities that affect any land or water use or any natural resource of a State's coastal zone must be carried out in a manner that is consistent to the maximum extent practicable with the enforceable policies of that State's federally approved coastal management program. The Forest Plan does not, by itself, authorize activities such as timber harvest or road construction that may affect the coastal zone. Thus, the Forest Plan does not have coastal effects. Site-specific activities that affect the environment require further site-specific analysis and public involvement under NEPA, CZMA, and other Federal and State environmental laws and regulations.

This finding of no coastal effects is consistent with the Memorandum of Understanding between the Forest Service and the State of Alaska concerning CZMA consistency reviews, which does not list forest plans as one of the activities expected to affect the coastal zone. The State of Alaska has never conducted a consistency review of a forest plan or a forest plan amendment or revision.

During the NEPA process for site-specific activities, the Forest Service will continue to determine whether the subject project has coastal effects, and whether an individual CZMA consistency review is required. Under the General Consistency Determination for Tongass Timber Sales, approved by the State of Alaska in December 2006, most timber sales conducted on the Tongass National Forest have been determined to meet or exceed the standards of the Alaska Forest Resources and Protection Act. Accordingly, most timber sales have been determined to be consistent to the maximum extent practicable with the enforceable policies of the Alaska Coastal Management Program, and do not require individual consistency review. Only those timber sales that require a State or Federal license or permit under a provision of law other than the Alaska Forest Resources and Protection Act require individual review under the CZMA for consistency with the Alaska Coastal Management Program.

Alaska National Interest Lands Conservation Act

The Alaska National Interest Lands Conservation Act (ANILCA), as amended, contains numerous provisions, including provisions regarding access, that apply to management of the Tongass National Forest. However, it is not necessary to address these provisions in the context of this decision. An ANILCA Section 810 evaluation and determination is not required for approval of a Forest Plan amendment, a programmatic-level decision that is not a determination whether to "withdraw, reserve, lease, or otherwise permit the use, occupancy, or disposition" of National Forest lands. However, a forest-wide evaluation and determination is included for the Forest Plan revision to facilitate future project-level planning and decisionmaking in compliance with ANILCA Section 810 (16 U.S.C. § 3120).

Consistent with Section 810 of ANILCA, the Forest Plan has been evaluated for potential effects on subsistence uses and needs. A cumulative effects analysis of resource developments on subsistence resources is included in the Final EIS (Chapter 3, “Subsistence”). Based on this analysis, implementation of the Forest Plan may result in a significant restriction to subsistence use of deer due to the potential effects of projects on the abundance and distribution of these resources, and on competition for these resources.

Two actions included in Section 810 were completed for the Draft EIS: (1) giving notice to the appropriate State agency, local committees and regional councils; and, (2) giving notice of, and holding, “a hearing in the vicinity of the area involved.” Because the area is the entire Tongass National Forest, such hearings were held in 23 communities throughout Southeast Alaska for the Draft EIS.

Also included in Section 810 is the determination that: “(a) such a significant restriction of subsistence uses is necessary, consistent with sound management principles for the utilization of the public lands, (b) the proposed activity will involve the minimal amount of public lands necessary to accomplish the purposes of such use, occupancy, or other disposition, and (c) reasonable steps will be taken to minimize adverse impacts upon subsistence uses and resources resulting from such actions.” I will now discuss each of these three points.

Necessity, Consistent with Sound Management of Public Lands. The amended Forest Plan has been examined to determine whether its potential for a significant restriction of subsistence uses is necessary, consistent with the sound management of public lands, as required by the Multiple-Use Sustained Yield Act, the National Forest Management Act, the Alaska National Interest Lands Conservation Act, the Tongass Timber Reform Act, and relevant State laws. The requirements of these laws have been reviewed and several of these have been discussed in this ROD.

The Forest Plan must be designed to provide a mix of resources and uses to best meet the needs of the American people. It must be designed to maximize net public benefits, as previously discussed. Some of the resource uses necessary to achieve these benefits have the potential to adversely affect subsistence uses within the Tongass. However, given the multiple-use mandate and the other requirements of law, these effects to subsistence uses are necessary, consistent with the sound management of public lands.

Amount of Public Land Necessary to Accomplish the Proposed Action Purpose. The amount of land necessary to implement the Forest Plan is, considering sound multiple-use management of public lands and the goals and objectives of the Plan, the minimum necessary. A forest plan must involve, by law, the entire forest. The plan does not authorize by itself any land-disturbing activities. Most of the Tongass National Forest, except the icefields, is used by one or more rural communities for subsistence deer harvesting. Many of the land use designations protect high value subsistence areas.

Reasonable Steps to Minimize Adverse Impacts Upon Subsistence Uses and Resources. The continuation of subsistence opportunities, and reasonable steps to minimize effects on subsistence resources, are provided for by the forest-wide standards and guidelines for subsistence, as well as related standards and guidelines for riparian areas, fish, and wildlife. Many important subsistence areas were assigned land use designations that exclude timber harvesting. The beach and estuary fringe forest-wide standards and guidelines apply to all beach fringe and estuarine areas not under more restrictive designations. Adverse impacts to subsistence uses and resources are minimized through these measures. The potential site-specific effects on subsistence uses, and reasonable ways to minimize these effects, will be analyzed and considered during project-level planning.

It is not possible to substantially reduce timber harvest in some areas by concentrating it in other areas without affecting subsistence resources and uses important to one or more rural communities. Also, concentrating timber harvest outside more important subsistence areas while still meeting the timber harvest goals of the Forest Plan could not be done without affecting the natural distribution of wildlife species, or without potentially significant effects to watersheds.

Clean Water Act

Full implementation of the Plan and this ROD is expected to maintain and improve water quality and satisfy all State water quality requirements. I base this finding on the extensive standards and guidelines contained in the Plan, the application of State-approved "Best Management Practices" specifically designed to protect water quality, and the discussion of water quality and beneficial uses contained in Chapter 3 of the Final EIS. Examples include the beach and estuary fringe areas, riparian buffers, and road design requirements. Additionally, project level analysis for subsequent activities under the Plan will be required to demonstrate compliance with Clean Water Act and State water quality standards.

Clean Air Act

At the scale of a programmatic plan such as this, the overall level of activities proposed under this decision is not anticipated to degrade air quality or violate State implementation plans. This finding is based on information presented in the Final EIS. The only non-attainment area within the vicinity of the Tongass National Forest is Juneau. Conformity determinations and more detailed air quality impact analyses will be made at subsequent levels of planning and analysis, where emissions can be more accurately quantified and reasonably forecasted and local impacts assessed.

Floodplains and Wetlands (Executive Orders 11988 and 11990)

These Executive Orders require Federal agencies to avoid, to the extent possible, short- and long-term effects resulting from the occupancy and modification of flood plains, and the modification or destruction of wetlands. Forest-wide standards and guidelines are provided for soil and water, wetlands, and riparian areas to minimize effects to flood plains and wetlands. They incorporate the Best Management Practices of the Soil and Water Conservation Handbook. The forest-wide standards and guidelines for beach and estuary fringe apply to all estuaries where less restrictive management might otherwise occur.

Environmental Justice (Executive Order 12898)

Executive Order 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations, requires each federal agency to make the achievement of environmental justice part of its mission by identifying and addressing disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority and low-income populations. The Order further stipulates that the agencies conduct their programs and activities in a manner that does not have the effect of excluding persons from participating in, denying persons the benefits of, or subjecting persons to discrimination under such programs, policies, and activities because of their race, color, or national origin.

The issue of environmental justice is analyzed within Chapter 3, Social and Economic Overview, of the Final EIS. The community assessment section indicates the per capita incomes (2000 Census), the population (2001, Alaska Department of Labor), the percent of Natives within the population (2000 Census), and recent trend and economic events for 32 Southeast Alaska communities. The analyses also includes discussions of potential timber harvesting within each community's use area, the potential impacts to the subsistence resources and land base used by each community, as well as potential impacts relative to recreation and tourism relative to each community.

The results of the analyses are very similar to those found in the 1997 Forest Plan Final EIS and the 2003 Forest Plan Final Supplemental EIS. I have concluded the amended Forest Plan results in a very low risk of disproportionate effects on minority or low-income populations in Southeast Alaska.

Civil Rights

Civil Rights are defined as "the legal rights of United States citizens to guaranteed equal protection under the law" (USDA Forest Service Manual 1730). Civil rights impact analysis for environmental or natural resource actions is part of the social impact analysis package in a necessary environmental impact statement and is not a separate report (USDA Forest Service Handbook 1709.11).

The Forest Service is committed to equal treatment of all individuals and social groups in its management programs in providing services, opportunities and jobs. Because no actual or projected violation of legal rights to equal protection under the law is foreseen under the Forest Plan for any individual or category of people, no civil rights impacts are reported in the Final EIS.

Implementation

Plan Effective Date

There are two different regulatory provisions governing the effective date for the amended Forest Plan. The NFMA planning regulations state that "[T]he approved plan shall not become effective until at least 30 days after publication of the notice of availability of the final environmental impact statement in the Federal Register…." (36 CFR § 219.10(c)(1).) The applicable appeal regulation states that "[I]mplementation of any decision subject to appeal pursuant to this part shall not occur for 7 calendar days following publication of the legal notice of the decision as required in this part." (36 CFR § 217.10(a).)

Therefore, the approved Tongass National Forest Land and Resource Management Plan Amendment is effective 30 days after the Notice of Availability of the Final EIS is published in the *Federal Register*, or 7 calendar days following publication of the legal notice of this decision in the Juneau Empire and the Anchorage Daily News, whichever is later.

Effective Direction

During the long and complex history of forest planning on the Tongass, many planning documents (forest plans, environmental impact statements, and records of decision) have been prepared. While all of these documents are useful and often build upon each other, it can be confusing to the public and to Forest Service employees searching for management direction or information to use in project level analysis. The planning record for the 2008 Tongass Forest Plan Amendment includes a summary of the current status of each of these documents.

In terms of management direction, this 2008 Record of Decision and the amended Forest Plan supersede all past forest plans and records of decision for the Tongass National Forest.

Continuing the Partnership with the State of Alaska

As described in a previous section of this ROD, the State of Alaska has participated as a cooperating agency in all phases of the planning process for this Forest Plan Amendment, under an MOU signed in 2006. The Forest Service and the State find it desirable to continue this relationship to promote effective and coordinated implementation of the Plan. Accordingly, as directed in the section of this ROD describing the decision, the Forest Supervisor will develop a comprehensive cost-sharing agreement with the State of Alaska regarding implementation of the 2008 Forest Plan within six months of the effective date of the Plan. I expect the agreement to outline the relationship between the Tongass National Forest and the State of Alaska regarding implementation of the Forest Plan, monitoring and evaluation, and making changes in response to new information from monitoring or other sources within an adaptive management framework. The cost-sharing agreement should also outline the roles and responsibilities of the Forest Service and the State throughout this process.

Timber Sale Program Adaptive Management Strategy

The Timber Sale Program Adaptive Management Strategy restricts timber sales and associated road construction to a specified portion, or phase, of the ASQ land base until actual timber harvest indicates the need for a larger land base. Land management activities unrelated to timber sales are not affected by the Strategy. The map of land included in each phase of the Strategy is included on the compact disc of the Final EIS and is also available on the internet at www.fs.fed.us/r10/tongass/.

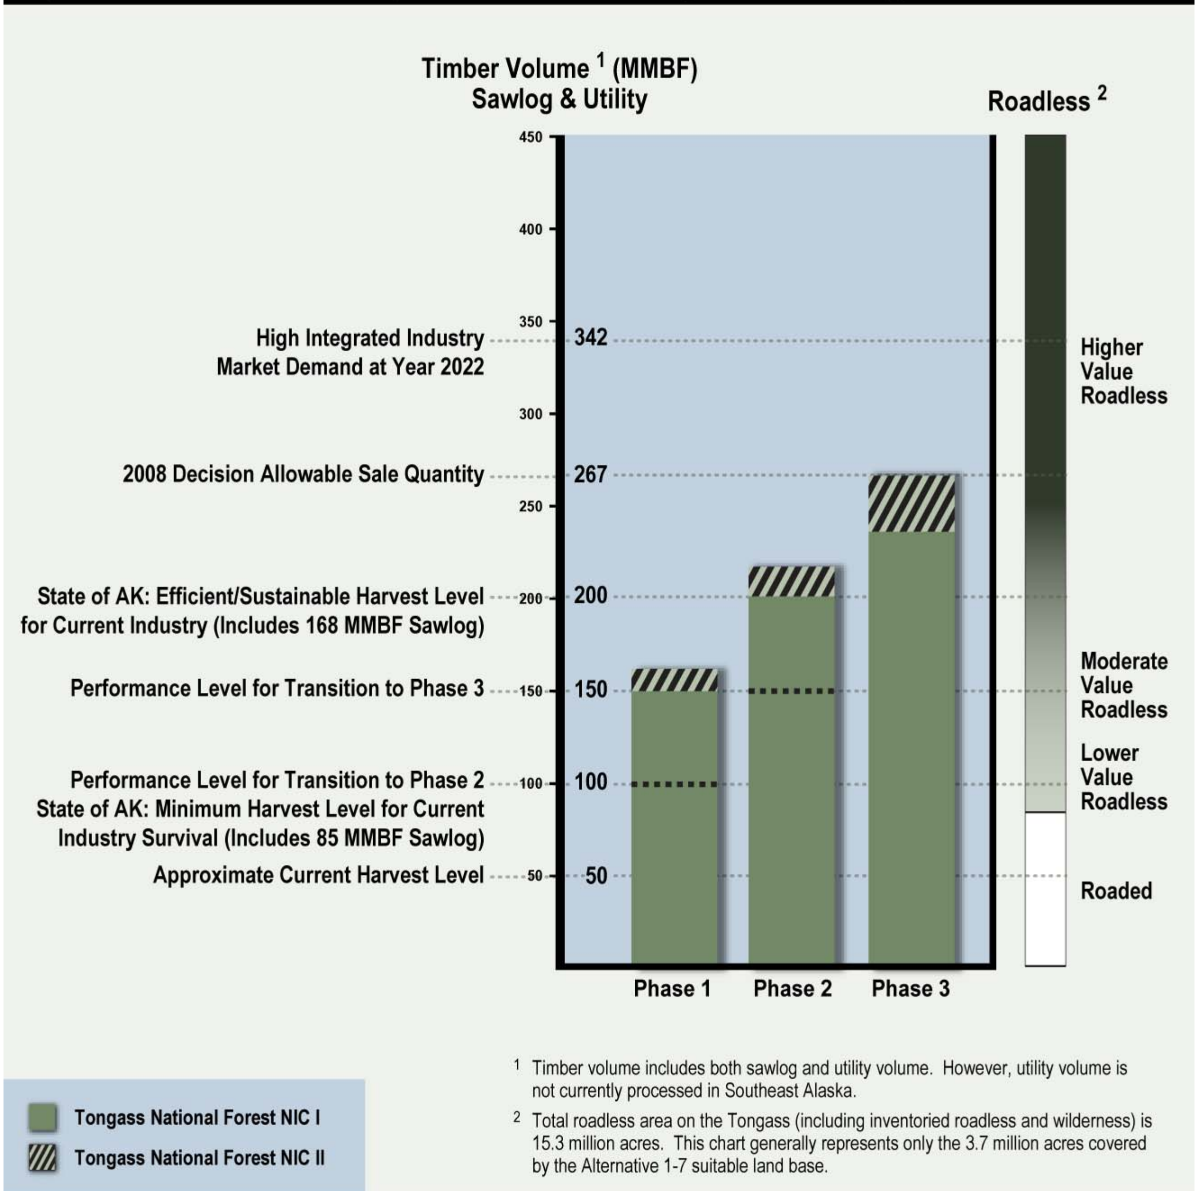
The Strategy is an extra step the Forest Service is taking to respond to recommendations from many parties that we avoid timber harvest and road construction in areas of the Tongass that are perceived as being more environmentally sensitive unless demand materializes to warrant such activity in those areas. The Strategy is based on three critical factors:

1. The long-term demand for timber from the Tongass is inherently very uncertain, and is influenced by the ability of all interested parties to work together to stabilize the timber supply.
2. The annual average ASQ of 267 MMBF is considerably higher than the current level of timber harvest on the Tongass.
3. The land base associated with the ASQ includes roadless areas, many of which are highly valued by substantial portions of the public.

As noted earlier, and as depicted in Figure 1, the VCUs in the Alternative 6 suitable land base have been evaluated according to each VCU's roadless values. The land base includes Roaded, Lower Value, Moderate Value, and Higher Value Roadless components. The Roadless column on the right side of the figure can be compared with the corresponding volume numbers on the left. The volume numbers reflect the estimated sustainable level of timber harvest associated with that portion of the land base. In general, a sustained harvest level of 100 MMBF would require the Roaded and much of the Lower Value Roadless portion of the land base; a level of 150 MMBF would require Roaded, Lower Value Roadless and some Moderate Value Roadless portions; a harvest level of 200 MMBF would require most of the remaining Moderate Value Roadless portions. Any harvest level over 200 MMBF would require entry into some of the Higher Value Roadless portions of the suitable land base.

Figure 1 also displays information received from the State of Alaska regarding the threshold levels of economically feasible Tongass timber sale volume that the State and the Forest Service believe are necessary over the short, medium, and long term. The State estimates that the currently operating sawmills need at least 83.5 MMBF of economically feasible sawtimber to remain in operation over the next one to two years. Over the longer term, an annual offer level of 167.5 MMBF of economic sawtimber from the Tongass would allow existing mills to operate efficiently, meaning two shifts per day, which would substantially increase their ability to compete in world markets. This level would also provide 30 MMBF annually for the veneer plant in Ketchikan to process low grade sawlogs. The majority of this volume would be derived from NIC I lands, which are more economically feasible because the timber can be harvested from them using conventional logging systems. Some volume from intermixed NIC II lands would also be included. When the utility volume is included, for which no processing facilities currently exist in Southeast Alaska, the total annual offer level needed from the Tongass to sustain the existing sawmills and veneer mill operating at efficient levels would be approximately 200 MMBF. The Strategy includes three phases:

Figure 1. Timber Sale Program Adaptive Management Strategy



Phase 1 – Phase 1 includes most of the roaded portion of the ASQ land base, along with most of the lower value inventoried roadless areas. The Phase 1 portion of the land base could sustain a level of timber harvest of about 150 MMBF. The scheduled timber sale program will generally be confined to this land base until such time as the level of timber harvest reaches at least 100 MMBF for two consecutive years. Personal use of timber, micro sales,[22] salvage sales, small commercial timber sales generally less than one MMBF, young-growth management projects, and the roads associated with these activities, would be allowed in development LUDs outside of the Phase 1 portion of the ASQ land base. Total scheduled timber harvest will be monitored each fiscal year and will count toward both ASQ and the 100 MMBF performance level. Timber harvest conducted in non-

[22] Micro sales are timber sales on Prince of Wales Island of down or dead trees totaling no more than 50 thousand board feet, to supply small niche-market timber processors.

development LUDs for purposes other than timber production (e.g., wildlife habitat improvement) will not count toward either ASQ or the Adaptive Management Strategy's performance levels.

Phase 2 – Phase 2 includes Phase 1 lands and most of the moderate value roadless areas. The Phase 2 portion of the ASQ land base could sustain a level of timber harvest of about 200 MMBF. The scheduled timber sale program will generally be confined to this land base until such time as the level of timber harvest reaches at least 150 MMBF for two consecutive years. Personal use of timber, micro sales, salvage sales, small commercial timber sales generally less than one MMBF, young-growth management projects, and the roads associated with these activities, would be allowed in development LUDs outside of the Phase 2 portion of the ASQ land base. Total scheduled timber harvest will be monitored each fiscal year and will count toward both ASQ and the 150 MMBF performance level. Timber harvest conducted in non-development LUDs for purposes other than timber production (e.g., wildlife habitat improvement) will not count toward either ASQ or the Adaptive Management Strategy's performance levels.

Phase 3 – Phase 3 includes the remaining ASQ land base.

In each phase, timber sale planning and sale preparation will be done within the corresponding portion of the land base (with the exceptions noted above for micro sales, small sales, salvage sales, and young-growth projects) until actual timber harvest performance indicates transition to the next phase is needed. The transition from one phase to the next must occur at a level lower than the maximum sustainable harvest level of the phase due to the lag time required for the timber sale planning process to be completed. This will allow flexibility for the Forest Service to complete the NEPA process and prepare a volume of timber ready to be offered for sale (referred to as shelf volume) ahead of actually offering the timber for sale (timber sold but not harvested is referred to as volume under contract). Adequate volume must be maintained in each category to respond quickly to short-term increases in harvest levels. A portion of shelf volume will normally be offered for sale each year to maintain an adequate level of volume under contract. Essentially, shelf volume replaces volume harvested each year, and would also be available for any new processing facilities that may be built. The amounts needed in these categories are a volume under contract equal to three years of volume harvested, and shelf volume equal to an additional three to five years of volume harvested. To the degree the Forest Service is successful in maintaining these levels, the transition from one phase of the Strategy to another will be seamless. The levels of volume available will be determined by the amount of funding appropriated by Congress; the ability of the Forest Service to prepare and offer economic timber for sale; and the ability of industry to purchase, harvest, process, and sell their products.

Timber Sale Economics

Providing economic timber sales in Southeast Alaska has always been a challenge and is expected to remain so into the future. The basic lack of infrastructure in a relatively isolated and harsh environment significantly affects development and operational costs. Earlier timber sale programs included significant investments in infrastructure development to aid individual timber sales be more economic. In recent years, investments in deferred road maintenance and construction of long term system roads in timber sale project areas has helped ensure timber sales are economic. Timber sale planning and the manner in which Forest Plan standards and guidelines are applied to specific timber sales can have significant cost consequences on the sales. Since 1997, monitoring of timber sale projects and of the implementation of the Forest Plan has revealed inconsistent interpretation and application of certain Forest Plan standards and guidelines, with resulting adverse consequences on timber sale economics. Similar issues that affect timber sale economics arose during the Forest Plan 5-Year Review and the review of the Forest Plan's conservation strategy. Evaluation of this issue during preparation of the 2008 Forest Plan Amendment indicates timber sales can be designed to be economic under most market conditions if the Forest Plan standards and guidelines are consistently interpreted and applied within the intent of the Forest Plan. Forest Plan implementation training will be conducted to ensure that the Plan is implemented consistently, effectively, and efficiently. This will include training in planning timber sales to fully meet the intent of the Forest Plan and also to be as economic as possible. Implementation of the 2008 Forest Plan will be monitored. If it is determined that the Plan unnecessarily affects the ability to produce economic timber sale projects, an amendment following similar processes as this effort will be conducted, focusing on opportunities to promote economic timber sales without compromising the Forest Plan goals and objectives. It must also be noted that investments in some infrastructure will still be necessary, especially as forest plan implementation progresses into phases 2 and 3 of the Adaptive Management Strategy.

Forest Plan Implementation Demonstration Area

During the Five-year Review of the 1997 Forest Plan, and through our consultation with the State of Alaska on this Amendment, it became evident that a more rigorous evaluation of the effectiveness of the Forest Plan could be accomplished if done at a scale wider than an individual watershed or a single project. Significant components of the Plan that warrant such evaluation include the conservation strategy (both the system of old-growth reserves and the set of standards and guidelines that apply to the development LUDs), access and travel management planning and design, young-growth management in the maturing stands, restoration of habitat in non-development LUDs, and effects of invasive species (terrestrial and aquatic).

Consequently, I direct the Tongass Forest Supervisor to explore developing a demonstration area of sufficient scale to test full implementation of the amended Forest Plan. Anticipated results of implementing the Forest Plan would be compared with actual results of such implementation. Where results differ significantly, modifications of the Forest Plan would be considered through the amendment or revision process. The ideal location for the project would be a roaded island with the following additional characteristics:

- No city or town.
- Low roadless values in portions of the island without roads.
- An adequate diversity of wildlife and fish species to monitor changes over time.
- A conservation strategy following the Forest Plan guidance.
- A wide range of previously harvested areas to provide several age classes of young-growth stands.
- Adequate access to provide for extensive monitoring and visitation of the area.

For this project to succeed, a collaborative effort would need to be developed between research, special interest groups, the State of Alaska, communities in the immediate vicinity of the project area, and other agencies interested in the results. The purpose of this collaborative effort would be to select the site and to ensure appropriate monitoring is performed to address the main questions relative to the effectiveness of the Forest Plan components.

Transition to the Amended Forest Plan

The amended Tongass Forest Plan does not provide final authorization for any activity, including timber sales, nor does it compel that any contracts or permits be advertised or awarded. Rather, like the 1997 Forest Plan, it provides a programmatic framework within which project-level decisions are considered. Projects must undergo appropriate site-specific analysis, and comply with applicable requirements for public participation, environmental analysis and disclosure, and the administrative appeal procedure before final authorization and implementation.

Exercising my discretion under NFMA, I have determined that it is not necessary to apply the amended Plan's standards and guidelines retroactively, and I find that NFMA does not require revision of any pre-existing use and occupancy authorizations. However, I have also determined that the Forest Service has the discretion, on a case-by-case basis, to modify pre-existing authorizations if they are not consistent with newly established standards, including the standards and guidelines in the amended Plan.

Because this was an amendment of the 1997 Plan, much of the management direction of the 1997 Plan is carried forward relatively unchanged into the amended Forest Plan. Therefore, many existing projects and ongoing actions that were consistent with the 1997 Plan will continue to be so with the amended Forest Plan. Many management actions decided prior to the issuance of this Record of Decision are routine and ongoing. Those decisions will generally be allowed to continue unchanged because implementing pre-existing decisions and the associated effects of that implementation were considered as part of the baseline and assumed to continue in the environmental analysis of alternatives in the Final EIS for the 2008 Forest Plan Amendment. Because we considered these earlier decisions in our effects analysis, their implementation is not in conflict with the amended Plan.

Existing timber sale contracts, in most cases, will be completed within three years. Other use and occupancy agreements may have a substantially longer life than timber contracts. These use and occupancy agreements will be reviewed to determine if or when the Forest Supervisor should exercise discretion to bring them into full compliance with the amended Forest Plan. As discussed below, recent project decisions that have not yet been implemented will be reviewed and adjusted, if necessary, in consideration of the new standards and guidelines in the amended Forest Plan.

Timber Sales

The relationship of 3 categories of timber sale projects to the amended Forest Plan is described below. Additional work on timber sale projects in Categories 2 and 3 (described below) will be done only to the degree such work is consistent with the Timber Sale Program Adaptive Management Strategy and any LUD changes included in the amended Forest Plan. If any portion of any project in Categories 2 or 3 is in a non-development LUD under the amended Forest Plan, that portion may not be implemented and no further planning work may be done unless the project is consistent with the management direction of the amended Forest Plan (e.g., it is being proposed for purposes other than timber production, such as wildlife habitat improvement).

The three categories of timber sale projects are as follows:

1. **Timber sales under contract before the effective date of this Plan.** I have decided not to modify any existing timber sale contracts. As I stated earlier, the effects analyses contained in the Final EIS assumed that these contracts would be executed according to their terms. Moreover, the environmental effects of these 36 projects have been disclosed to the public through their site-specific project-level environmental documents. Since existing timber sale contracts will generally be completed within three years, I find it reasonable to allow pre-existing standards to remain in effect for that period of time. The sales included in this category as of December 31, 2007 are listed below. Any timber sale contract signed between that date and the effective date of the amended Forest Plan will also be included in Category 1.

Timber Sales in Category 1--Under Contract--as of December 31, 2007

Above Road	Microsale #27
Ambrosia	Microsale # 126
Angel	Microsale #136
Backline	Microsale #137
Beaver Tail Special	Microsale #138
Big Bear	Microsale #139
Blind Slough	Midpoint Special Salvage
Bogo	Midway Reoffer II
Bohemia	Mink Tail Special Salvage

Dogleg Special Salvage	Scratchings
Drumlin Reoffer II	Setter Lake
Finger Point	Shady
Fishsticks	Skipping Cow
Fishtrap Special Salvage	Small Otter
Fourleaf	Summore Change
Kensington Gold Project	Swan Tyee Timber Settlement
Kensington Settlement	Swingset Special Salvage
Kogish Shinaku II	Tall Tree
Kosciusko Stewardship	Three Moose
Last Call Reoffer	Turbo Otter
Licking Creek	Tuxekan
Lindenberg	Twin Shovel
Little Rock	Upper Carroll II
Low Ridge	Vientos Cinco #5
Luck Lac II	Wedge
Lucky Charm Reoffer	11 Permits
Lucky Duck Reoffer	

2. **Timber sale projects: (a) for which NEPA decision documents were signed before the effective date of this Plan, but whose timber volumes will not have been sold (wholly or in part) before the effective date of this Plan; (b) with a Final Environmental Impact Statement and no Record of Decision as a result of the May 18, 2007 Settlement Agreement in *Natural Resources Defense Council v. Forest Service*, Case No. 1:03-cv-00029-JKS (approved by the Alaska District Court on May 25, 2007); or (c) now being planned and for which a Draft Environmental Impact Statement has been released for public comment before the effective date of this Plan.** I have reviewed the 43 projects in this category and have determined that the 36 projects listed below are consistent with the goals and objectives of the amended Plan.[23]

[23] The environmental documents for seven projects in Category 2 cannot be found consistent with the amended Forest Plan without additional environmental analysis. These projects include Eight Fathom, Southeast Chichagof, Alaska Pulp Company Final Supplement to the EISs for the 1986-1990 Operating Periods, Kelp Bay, Northwest Baranof, Indian River, and Ushk Bay. Accordingly, any further work on these projects would require the issuance of a new draft EIS; therefore, these projects are treated as if they are in category 3.

Moreover, the environmental effects of these 36 projects have been disclosed to the public through their site-specific project-level environmental documents. These projects were also assumed to be implemented in the environmental analysis of Alternatives 5 and 6 in the 2008 Forest Plan Amendment Final EIS. Because the Final EIS considered these projects in its effects analysis, their implementation is not in conflict with the amended Plan.

I am directing the Forest Supervisor to review these projects, and incorporate the new direction in the amended Forest Plan to the extent this can be done without causing major disruptions in the implementation of these projects. Among the changes to be considered are the legacy standard and guideline in lieu of the 1997 Plan's standards and guidelines for goshawk foraging and marten habitat, and the new direction regarding probable goshawk nests. The Tongass Change Analysis Process[24] will be used on a project-by-project basis to determine whether additional environmental analysis and public involvement are necessary, and to document any modifications to the project in the project record.

The amended Forest Plan includes the new scenery management program, which is a replacement for the visual management system included in the 1997 Forest Plan. The two programs are essentially the same insofar as environmental effects are concerned, and the transition should be initiated only for new timber sale projects. I find that projects planned under the visual management system do not require changes to the scenery management program included in the amended Forest Plan.

Timber Sales Included in Category 2

Backline	Kosciusko
Baht	Kuiu
Bohemia Mountain	Madan
Boundary	Lab Bay
Canal Hoya	Navy
Chasina	Overlook
Cholmondeley	Roadside
Control Lake	Scott Peak
Couverden	Scratchings
Crane and Rowan Mountain	Sea Level
Crystal Creek	Soda Nick
Doughnut	Todahl Backline
Emerald Bay	Traitors Cove
Finger Mountain	Tuxekan
Goose Creek	Woodpecker 2002
Gravina	Woodpecker 2003
Heceta Commercial Thinning	Yakutat Salvage
Iyouktug	Yakutat Small Sales

3. **Timber sale projects for which a Draft Environmental Impact Statement has not been released for public comment before the effective date of this Plan.** These projects shall be based on the amended Plan and will be consistent with all applicable management direction.

[24] This process includes a review of new information and circumstances relevant to environmental concerns to determine if additional analysis is warranted.

Administrative Appeal Rights

This decision to amend the Tongass Forest Plan is subject to administrative review pursuant to 36 CFR Part 217. The Notice of Appeal must be in writing, meet the content requirements specified at 36 CFR 217.9, and be filed with the Reviewing Officer:

Regular Mail: Abigail Kimbell, Chief
USDA Forest Service
Attn: EMC Appeals
Mail Stop 1104
1400 Independence Avenue., SW
Washington, DC 20250-1104

Note that regular mail is irradiated before it is delivered to the National Headquarters, so regular mail may take longer than normal to arrive. Anything time sensitive should be sent via FedEx, UPS, Courier, etc. to the following address:

USDA Forest Service
Ecosystem Management Coordination
Attn: Appeals
Yates Building, 3CEN
201 14th Street, SW
Washington, DC 20250

Email Address: appeals-chief@fs.fed.us
Phone: 202-205-0895
Fax: 202-205-1012

Electronic appeals must be submitted in a format such as an email message, plain text (.txt), rich text format (.rtf), or Word (.doc). Appeals may also be hand delivered to the courier address above between the hours of 8:00 AM and 5:00 PM Monday through Friday, except Federal holidays.

The Notice of Appeal, including attachments, must be filed (regular mail, fax, email, express delivery, courier service, or hand delivered) with the Reviewing Officer at the correct location within 90 calendar days of the date the legal notice of this decision is published in the Juneau Empire and the Anchorage Daily News. The publication date in the newspapers of record is the exclusive means for calculating the time to file an appeal. Those wishing to appeal this decision should not rely upon dates or timeframe information provided by any other source.

I encourage anyone concerned about this decision, the Forest Plan, or the Final EIS, to contact the officials listed below before submitting an appeal. It may be possible to resolve the concern in a less formal manner.

Tongass Land and Resource Management Plan

Final Environmental Impact Statement

Plan Amendment

SUMMARY

Tongass National Forest

Welcome

This Summary accompanies the Final Environmental Impact Statement (EIS) for a proposed amendment of the Tongass Land and Resource Management Plan (Forest Plan). Also included with the Summary are the Record of Decision (which selects Alternative 6 with minor modifications) and the amended Forest Plan. Most reviewers will receive an electronic version of these documents on a CD. The CD contains a cover letter, the Final EIS in two volumes, alternative maps, the Record of Decision and its accompanying maps, the Forest Plan, and a number of reference maps. These documents and maps are described when you open the CD.

A comprehensive Web site covering the Forest Plan adjustment process was developed to assist the public in reviewing and commenting on the various documents and maps developed during the process. This site will continue to be available at www.tongass-fpadjust.net for a period of time. At some point in the near future, this site will be removed, and the important documents will be transferred to the main Tongass Web site at www.fs.fed.us/r10/tongass.

Publication of the Notice of Availability for the Final EIS in the Federal Register will initiate a 90-day appeal period. The closing date of the appeal period will also be posted on the project Web site.

How to Use the CD

The CD-ROM has an "autostart" feature that should start the application when you put the CD in your computer. If the application starts correctly, a Welcome page containing links to the documents should open up. If the CD does not start by itself shortly after you insert it in your CD drive, then simply double-click on the Index.htm file on the CD.

Introduction

Land and Resource Management Plans (Forest Plans) are required by the National Forest Management Act (NFMA) of 1976. The 16.8-million acre Tongass National Forest, the largest forest in the National Forest System (NFS), was the first to complete a Forest Plan under the NFMA. The original Tongass Forest Plan was approved in 1979 and amended in 1986 and 1991. The Forest Plan revision process began in 1987 and the Final EIS, Record of Decision (ROD), and the revised Forest Plan were published in 1997. A Supplemental EIS that evaluated the wilderness potential of roadless areas was completed in 2003. The revised Forest Plan has been amended 28 times since 1997, primarily to adjust Old-Growth Habitat reserve boundaries and designate electronic/communication sites.

An August 2005 Ninth Circuit Court of Appeals ruling and the 5-Year Forest Plan Review, which was completed in January 2005, indicated the need to consider amending the Tongass Forest Plan. This 2008 Final EIS responds to the Court and the 5-Year Review by analyzing six alternatives for amending the Forest Plan in addition to the No-Action Alternative (Alternative 5). A separate document called the Proposed Forest Plan was published with the Draft EIS and represented the complete Forest Plan including all proposed amendments.

Purpose and Need

The purpose and need for this EIS is to respond to the Ninth Circuit Court's decision in *Natural Resources Defense Council vs. U.S. Forest Service* (421 F.3d 797, August 5, 2005). In that decision, the Court held that the EIS and ROD for the 1997 Forest Plan had errors relating to the use of projected market demand for timber, the range of alternatives considered relative to the market demand calculations, and the cumulative effects of activities on non-NFS lands. In addition, there is a need to consider adjustments to the Plan based on information generated during the 5-Year Review of the Forest Plan. Therefore, the purpose and need for this EIS primarily relates to the August 2005 Court decision, the 5-Year Plan Review, and other minor clarifications and updates.

Issues

Identification of issues helps define or predict the resources or uses that could be most affected by the management of NFS lands. These issues are then used as a basis to formulate management alternatives or to measure differences between alternatives.

Ten public issues were originally identified in 1988 for the Forest Plan Revision. These original issues included scenic quality, recreation, fish habitat, wildlife habitat, subsistence, timber harvest, roads, minerals, roadless areas, and local economy. The 1991 Forest Plan Revision Supplemental Draft EIS (SDEIS) added an additional concern: identifying and considering rivers for recommendation as Wild, Scenic, and Recreational rivers.

After the release of the 1991 SDEIS, considerable new information pertaining to the Tongass Forest Plan Revision became available. Out of this information emerged five additional issues, determined by the Regional Forester as needing more study and evaluation before a final revised Forest Plan could be adopted. Some of these issues were aspects or extensions of the ten public issues previously considered; others were new issues or had not been considered as issues in themselves. The five issues included wildlife viability, fish habitat, karst and caves, alternatives to clearcutting, and socioeconomic considerations. These issues were assessed in the 1996 Revised SDEIS and the 1997 Tongass Forest Plan Revision Final EIS.

The 2003 Supplemental EIS (SEIS) reviewed and evaluated roadless areas and analyzed alternative groupings of roadless areas for wilderness recommendations. Two broad issue categories, referred to as key issues, were identified as the major issues driving the SEIS alternatives analysis: 1) the long-term protection of roadless areas and associated values and 2) the social and economic well-being of the communities of Southeast Alaska.

Public Input

The scope of this EIS was initially determined by the Court in its 2005 ruling, and by the 5-Year Review of the Forest Plan. Additional information was considered to help clearly define the issues and for use in the development and analysis of alternatives. For the Final

EIS, comments and information from a wide variety of public inputs that were related to amending the Forest Plan were considered. This information included the following:

- Public comments generated during the 1997 Tongass Forest Plan Revision process;
- Tongass Forest Plan Revision appeals;
- Public input specific to the Tongass National Forest on the Forest Service's 2001 National Roadless Area Conservation Rule;
- Public comments generated relative to the 2003 SEIS;
- Public input expressed during project-level National Environmental Policy Act (NEPA) analyses over approximately the past 10 years; and
- Public input received in response to the Notice of Intent and the Web site for this EIS.

This record of public input on the management of the Tongass covers a period of more than 12 years. Of special note are the extensive public meetings held in Southeast Alaska for the 1997 Forest Plan Revision, the 2001 National Roadless Area Conservation Rule, and the 2003 SEIS.

In addition to the above, public involvement has occurred during the development of this EIS. Public involvement activities have included the following:

- The Notice of Intent was published in the Federal Register in March 2006.
- A Forest Plan Adjustment Web site was developed in January 2006 and has been maintained and continually updated to inform and engage the public since then. Several hundred comments and questions were received through the Web site or via emails associated with the Web site during the first several months of its operation.
- A Weblog regarding the Forest Plan adjustment effort was established in July 2006 and was maintained as another method of public communication.
- In response to the three above items, a number of letters were received containing comments regarding the issues and alternatives.
- Government-to-government consultation was conducted with federally recognized tribes.

- A number of group-specific meetings were conducted with various organizations (including Alaska Native groups).
- A variety of news releases were issued relative to the Forest Plan adjustment process.
- A series of ongoing meetings by a group known as the Tongass Futures Roundtable (hosted by the National Forest Foundation and The Nature Conservancy) resulted in considerable discussion of Tongass management issues among a broad spectrum of individuals and groups interested in the future of Southeast Alaska.
- Input received prior to issuance of the Draft EIS was reviewed and synthesized and a summary of this synthesis is presented as Appendix A (Issue Identification) to the Final EIS.
- A Draft EIS and Proposed Forest Plan were released on January 12, 2007. This began a 90-day comment period, which was later extended to 108 days. The comment period closed on April 30, 2007.
- During the comment period, open houses and public hearings were held in 24 Alaska communities. In addition to comments on the Draft EIS, the hearings provided opportunities to hear concerns related to subsistence and Alaska Native issues.
- On March 22, 2007, an open house and public hearing was held on the internet to solicit public comment in an open forum from individuals living anywhere in the world.

More than 84,000 comment documents were received, including individual letters, form letters, emails, hearing testimony, and comments submitted directly via the Forest Plan Adjustment Web site. Slightly more than 2,000 of these were classified as individual comment documents and the others were classified as form letters and emails. The individual comment documents were subdivided into approximately 5,500 individual comments. Responses were received from all 50 states and 89 foreign countries. A summary of the substantive comments and Forest Service responses to those comments is presented in Appendix H to the Final EIS (Volume II).

The Three Focus Issues

Key Issues

Any alternative that proposes to change the Forest Plan could affect resources and/or outputs relative to the current Forest Plan. Therefore, Chapter 3 of the EIS shows the effects of the various alternatives on all relevant resources and evaluates their effects relative to all of the issues and concerns previously identified during the 1997 Plan revision process. However, based on the purpose and need of this EIS and public input received during the current EIS process, some issues are more likely to influence the comparison among alternatives and represent the major issues to be evaluated. These issues were grouped into three broad issue categories, referred to as the key issues. These key issues are the major issues driving the alternatives and analyses.

Key Issue 1 – Protection of high value roadless areas from road development and timber harvest activity on the Tongass is of local and national importance, particularly for wildlife and biodiversity, recreation, and tourism.

Many people believe that roadless areas should be allowed to evolve naturally through their own dynamic processes and should be afforded protection to ensure that this will occur. The Tongass includes very large undeveloped land areas, with several portions of the Forest consisting of contiguous roadless areas that exceed 1 million acres and represent large, unfragmented blocks of wildlife habitat. This large scale of roadless lands does not exist anywhere else in the NFS, except on the Chugach National Forest in Southcentral Alaska.

Roadless areas are considered important because of their wildlife habitat and recreation values and their importance for tourism. They are also important because of the passive use values and ecosystem services values they provide. Passive use values represent the value that individuals assign to a resource independent of their use of that resource and typically include existence, option, and bequest values. These values represent the value that individuals obtain from knowing that expansive roadless areas exist, knowing that they are available to visit in the future should they choose to do so, and knowing that they are available for future generations to inherit. There is interest in preserving large portions of the Tongass because the majority of the Forest is in a natural condition, unlike most other national forests, and the Tongass represents a significant portion of the world's remaining temperate rainforests.

Ecosystem services represent the services provided to society by healthy ecosystems. These services and benefits include what some consider to be long-term life support benefits to society as a whole. Examples of ecosystem services include watershed services, soil stabilization and erosion control, improved air quality, climate regulation, carbon sequestration, and biological diversity.

Indicators: Analysis relative to this issue compares the amount and proportion of land protected in non-development land use designations (LUDs); the amount of inventoried roadless areas that would be protected under each alternative; and the amount of productive old-growth forest that would be protected under each alternative. The values of the lands protected are considered. Passive use or ecosystem services values are discussed qualitatively, with examples provided from other studies.

Key Issue 2 – The Tongass National Forest needs to provide a sufficient timber supply to meet the market demand and help maintain a vibrant economy in Southeast Alaska.

The Tongass Timber Reform Act (TTRA) (Section 101) requires the Forest Service to seek to provide a supply of timber from the Tongass National Forest that meets annual market demand and the market demand for each planning cycle, consistent with providing for the multiple-use and sustained yield of all renewable resources. With the cancellation of long-term contracts and the closure of two Southeast Alaska pulp mills, the timber industry in Southeast Alaska has been in a period of transition. Future or planning cycle demand scenarios, however, cover a wide range and depend on rates of economic growth in key markets, conditions faced by competitors, and the rate of investment and innovation in manufacturing in Alaska.

Over the past half a century, the timber industry has been a major component of the economy of Southeast Alaska. However, with closure of the two Southeast Alaska pulp mills in the 1990s and growth of the tourism economy, timber has played a lesser role in recent years. Because the economy of Southeast Alaska is based on relatively few industries, maintaining an active timber industry is important for maintaining a well-diversified economy.

Indicators: Analysis relative to this issue compares the likely demand for timber and the amount of harvest made available to meet that demand. It considers the type of wood (sawlogs vs. utility wood) made available and the usefulness of that wood type to the local industry. The analysis also considers the effects on regional and national economies and on local communities.

Key Issue 3 – Protection of wildlife habitat and biodiversity on the Tongass is of local and national significance and is affected by road development and timber harvest activities.

The Tongass National Forest supports a unique and important assemblage of wildlife, including the largest population of brown bears and breeding bald eagles in the world, species of high importance for subsistence (e.g., Sitka black-tailed deer), an extensive array of endemic mammals and other species, and a large number of species that are at least partially dependent on old-growth habitats (e.g., marten and goshawk). Populations of many of these species and the biodiversity of Southeast Alaska are affected by timber harvest and the development of roads.

Although less than 10 percent of the productive old-growth habitats on the Tongass have been converted to young growth, this percentage is much higher for certain types of old growth, such as low-elevation and large-tree old growth. In addition, a high percentage of non-NFS lands have been harvested and the rate of harvest is much higher on these lands. Therefore, the cumulative effects of harvest and road building on wildlife of Southeast Alaska are greater than the effects of harvest and road construction on the Tongass alone.

Indicators: Analysis relative to this issue compares the amount of productive old-growth forest that would be protected under each alternative, as well as the percentages of biogeographic provinces that would be protected in reserves. It also considers the role of the managed lands (development LUDs) in providing wildlife habitat. It rates the alternatives in terms of the expert panel ratings conducted for the 1997 Forest Plan Revision EIS. Habitat changes, as documented by habitat amounts, changes in road densities, and habitat models, are also used as indicators. Cumulative harvest and road development on non-NFS lands is quantified and evaluated in conjunction with harvest and road development on NFS lands.

Alternatives

Each alternative described in Chapter 2 of the Final EIS includes the following components:

- A framework;
- A general description of the desired condition;
- A table with the acreages allocated to each LUD;
- A map (included in the map packet accompanying the EIS hard copy or in the map section of the CD version) showing the distribution of LUDs across the Forest;
- A map showing the distribution of development, natural setting, and wilderness LUD groups;
- A description of proposed changes to the current Forest-wide standards and guidelines and management prescriptions; and
- A quantification of outputs and measures associated with each alternative.

The management prescriptions (i.e., LUD-specific standards and guidelines) for each LUD are included in the 1997 Forest Plan, as amended, for Alternative 5 (No Action) or in the Final Proposed Forest Plan (see below) for the action alternatives. The Forest-wide standards and guidelines that apply to each alternative are also included in these Forest Plans.

Chapter 2 of the Final EIS identifies the goals common to all alternatives. In addition, the TTRA (Section 101) direction for the Tongass to “seek to provide a supply of timber which 1) meets the annual market demand for timber from such forest and 2) meets the market demand from such forest for each planning cycle" is a goal for each alternative "to the extent consistent with providing for the multiple use and sustained yield of all renewable forest resources," as determined by that alternative, and subject to appropriations and applicable law.

Final Proposed Forest Plan

The No-Action Alternative (Alternative 5) represents the 1997 Forest Plan Revision, as amended to date. A number of changes to the Forest Plan text are being proposed under the action alternatives, based on the Forest Plan 5-Year Review and Forest Service staff recommendations. Most changes were incorporated into the Proposed Forest Plan that accompanied the Draft EIS. These changes were modified and updated for the Final EIS and the major changes being proposed are summarized below. The individual alternative descriptions on the following pages only identify items that are not consistent with the Final Proposed Forest Plan, which is defined by the Proposed Forest Plan that accompanied the Draft EIS, as modified in this section. A summary of the main changes that are incorporated into the Final Proposed Forest Plan are provided below.

Management Prescriptions

- Edits and clarifications were made regarding karst management programs, sacred site protection, minerals and geology, off-highway vehicle use, scenery management, and other areas for most LUD prescriptions.
- Substantial edits and clarifications were made to the Wilderness and Wilderness National Monument LUD prescriptions.

Forest-wide Standards and Guidelines

- Clarifications were made to the standards and guidelines regarding steep slopes and soil stability in the *Soils* and *Water* section.
- Clarifications were made to the standards and guidelines on Class III and IV streams and edits were made to the other standards and guidelines in the *Fish* section.
- The detailed stream process group-specific Riparian standards and guidelines are presented in an appendix in the Final Proposed

Forest Plan, instead of in the main body of the standards and guidelines, which is the way they were presented in the Proposed Forest Plan that accompanied the Draft EIS.

- A new section was added to Chapter 4 on Invasive Species.
- A new section was added to Chapter 4 on Plants.
- The Threatened, Endangered, and Sensitive Species standards and guidelines are incorporated into subsections under Fish, Wildlife, and Plants (as appropriate) in the Final Proposed Plan, instead of in a separate section as in the Proposed Plan that accompanied the Draft EIS.
- The goshawk foraging habitat and the marten habitat standards and guidelines in the *Wildlife* section were deleted and replaced with a Forest-wide legacy standard and guideline in the Proposed Forest Plan that accompanied the Draft EIS. In addition, the legacy standard and guideline for the Final Proposed Forest Plan was revised further. The revised standard and guideline requires legacy forest structure to be left only in harvest units greater than 20 acres and only in higher risk VCUs, as previously defined (49 VCUs).
- The goshawk nesting habitat standard and guideline in the *Wildlife* section was revised in the Proposed Forest Plan that accompanied the Draft EIS. In addition, the goshawk nesting habitat standard and guideline for the Final Proposed Forest Plan was revised further. The revised standard and guideline permits nesting habitat protection measures to be removed if, after 2 consecutive years of monitoring, evidence of confirmed or probable nesting is no longer observed.
- The requirement to conduct inventories to determine the presence of nesting goshawks for proposed projects that affect goshawk habitat is included in the Final Proposed Forest Plan (this was inadvertently removed from the Proposed Forest Plan that accompanied the Draft EIS).
- New standards and guidelines on sacred site protection were added in the *Heritage Resources and Sacred Sites* section.
- Extensive edits were made to the Karst and Cave Resources standards and guidelines and the Karst and Cave Resources appendix.
- Substantial edits were made to the Minerals and Geology standards and guidelines.

- Substantial edits were made to the Recreation and Tourism standards and guidelines. The detailed Recreation Opportunity Spectrum-specific standards and guidelines are presented in an appendix in the Final Proposed Forest Plan, instead of in the main body of the standards and guidelines, which is the way they were presented in the Proposed Forest Plan that accompanied the Draft EIS.
- The Scenery standards and guidelines were converted from the Visual Management System to the Scenery Management System.
- Edits were made to off-highway vehicle standards and guidelines in the *Lands* section.
- Edits were made to the road storage and decommissioning standards and guidelines in the *Transportation and Utilities* section.

In addition, there are a number of changes to other Forest Plan sections. These include changes to the Goals and Objectives (Chapter 2 of the Plan) and Monitoring and Evaluation (Chapter 6 of the Plan) chapters, as well as a number of the Forest Plan appendices, including Appendix B (Information Needs), Appendix F (Visual Priority Routes and Use Areas), Appendix I (Karst and Caves), Appendix K (Old-Growth Habitat Reserve Criteria), and Appendix L (Resource Schedules). The Monitoring and Evaluation chapter in the Final Proposed Plan was revised to be more focused, relative to the version in the Proposed Forest Plan that accompanied the Draft EIS. In addition, it is anticipated that the current list of Management Indicator Species (MIS) may be revised in the future, but a change in MIS is not part of the Final Proposed Plan.

Proposed LUD Changes Common to Most Alternatives

The LUD allocations for each alternative are described in the following alternative-specific descriptions. The alternatives do not vary in terms of the acreage allocated to congressionally designated areas (i.e., Wilderness, National Monument, and LUD II), nor do they vary in terms of allocations to Research Natural Areas, Enacted Municipal Watersheds, or Wild, Scenic, or Recreational River LUDs. However, they do vary with respect to the other non-development LUDs and all of the development LUDs. The LUDs for each alternative are displayed on alternative LUD maps that accompany the EIS.

The proposed expansion of the Special Interest Area LUD and the proposed replacement of the Young Bay Experimental Forest with the Cowee-Davies Experimental Forest are common to all alternatives except Alternative 5, which would follow the 1997 Forest Plan (as amended) for these two LUDs. In addition, the proposed expansion and refinement of the Old-Growth Habitat LUD is common under Alternatives 1, 2, 3, and 6, and is as a result of an interagency process completed in 2007. Under this process, the Tongass worked with the Alaska Department of Fish and Game and the U.S. Fish and Wildlife Service to conduct a comprehensive review and mapping effort for all small old-growth reserves (OGRs). The final proposal is included in Alternatives 1, 2, 3, and 6 of the Final EIS. Alternative 5 retains the 1997 Plan (as amended) reserve network and the reserves proposed under Alternatives 4 and 7 are not affected by this proposal. Further information on the refinement of small OGRs is included in Appendix D (Volume II).

Alternative 1

Under this alternative, forest management would provide a mix of national forest uses and activities, but would emphasize maintaining inventoried roadless areas, associated fish and wildlife values, and unroaded recreation, tourism, and subsistence opportunities, relative to the current Forest Plan. Timber would be managed within the roaded land base and inventoried roadless areas would remain in a natural condition. In addition, a number of higher value roaded areas, including all of Kuiu, Baranof, and Kruzof Islands, many portions of Chichagof Island, all mainland areas, and other areas, would be excluded from commercial timber management. A total of 840,000 acres of the Tongass would be in development LUDs and 15.9 million acres would be in non-development LUDs. The majority of the lands changed to non-development LUDs from development LUDs (in the 1997 Plan) would be designated Semi-Remote Recreation. Specific LUD changes under this alternative would include the addition and modification of a number of Geologic Special Interest Areas, recommendations to change the Young Bay Experimental Forest to Semi-Remote Recreation and the Cowee-Davies Creek watersheds from Scenic Viewshed to Experimental Forest, and converting a large area of Remote Recreation LUD north of Juneau to Semi-Remote Recreation. It also would include extensive refinements to the boundaries of the small Old-Growth Reserves, based on a recently completed interagency evaluation.

Alternative 1 would have 312,000 acres suitable for timber production and would have an Allowable Sale Quantity or ASQ (the maximum amount of timber that can be sold from the suitable land base on a sustained basis, expressed as an annual average) of 49 million board feet (MMBF). This alternative would approximately correspond with Scenario 1 (limited lumber production) of the Brackley et al. (2006a) timber demand study. It is similar to Alternative 8 of the 2003 SEIS in terms of the areas allocated to non-development LUDs.

Alternative 2

Under this alternative, forest management would provide a mix of national forest uses and activities, but would give additional emphasis to roadless areas, associated fish and wildlife values, and unroaded recreation, tourism, and subsistence opportunities, relative to the current Forest Plan. Timber would be managed within the roaded land base as well as within roadless areas with lower wilderness attribute ratings (primarily those adjacent to developed areas). The vast majority of current roadless areas would remain in a natural condition. A total of 1.9 million acres of the Tongass would be in development LUDs and 14.8 million acres would be in non-development LUDs. The majority of the lands changed to non-development LUDs from development LUDs (in the current Plan) would be designated Semi-Remote Recreation. All areas identified as development LUDs in Alternative 1 would also be development LUDs in this alternative, in addition to other areas. Specific LUD changes under this alternative would include the addition and modification of a number of Geologic Special Interest Areas, recommendations to change the Young Bay Experimental Forest to Semi-Remote Recreation and the Cowee-Davies Creek watersheds from Scenic Viewshed to Experimental Forest, and converting a large area of Remote Recreation LUD north of Juneau to Semi-Remote Recreation. It also would include extensive refinements to the boundaries of the small Old-Growth Reserves, based on a recently completed interagency evaluation.

Alternative 2 would have 545,000 acres suitable for timber production and would have an ASQ of 151 MMBF. This alternative would approximately correspond with Scenario 2 (expanded lumber production) of the Brackley et al. (2006a) timber demand study.

Alternative 3

Under Alternative 3, forest management would provide a mix of national forest uses and activities, but would give some additional emphasis to roadless areas, associated fish and wildlife values, and unroaded recreation, tourism, and subsistence opportunities, relative to the current Forest Plan. Timber would be managed within the roaded land base as well as within additional roadless areas; but these additional areas would not include the high value roadless areas identified in the 1999 Record of Decision (USDA Forest Service 1999) as the 18 Areas of Special Interest or the 23 areas proposed for wilderness in H.R. 987. The vast majority of current roadless areas would remain in a natural condition. A total of 2.8 million acres of the Tongass would be in development LUDs and 14.0 million acres would be in non-development LUDs. The majority of the lands changed to non-development LUDs from development LUDs (in the current Plan) would be designated Semi-Remote Recreation. All areas identified as development LUDs in Alternative 2 would also be development LUDs in this alternative, in addition to other areas. Specific LUD changes under this alternative would include the addition and modification of a number of Geologic Special Interest Areas, recommendations to change the Young Bay Experimental Forest to Semi-Remote Recreation and the Cowee-Davies Creek watersheds from Scenic Viewshed to Experimental Forest, and converting a large area of Remote Recreation LUD north of Juneau to Semi-Remote Recreation. It also would include extensive refinements to the boundaries of the small Old-Growth Reserves, based on a recently completed interagency evaluation.

Alternative 3 would have an estimated suitable forest land base of 661,000 acres and an ASQ of 204 MMBF. This alternative would approximately correspond with Scenario 3 (medium integrated industry) of the Brackley et al. (2006a) timber demand study. It is similar to Alternative 5 of the 2003 SEIS in terms of the areas allocated to non-development LUDs.

Alternative 4

Under Alternative 4, forest management would provide a mix of national forest uses and activities, but would give additional emphasis to timber management and associated economic stability of Southeast Alaska communities, relative to the current Forest Plan. Timber would be managed within an area expanded beyond the current Forest Plan. The vast majority of current roadless areas would remain in a natural condition; however, the majority of roadless areas that contain substantial productive old growth (POG), outside of wilderness, could be developed. A total of 4.7 million acres of the Tongass would be in development LUDs and 12.0 million acres would be in non-development LUDs. Almost all areas identified as development LUDs in Alternative 5 would also be development LUDs in this alternative, in addition to other areas. Specific LUD changes under this alternative would include the addition and modification of a number of Geologic Special Interest Areas, recommendations to change the Young Bay Experimental Forest to Semi-remote Recreation and the Cowee-Davies Creek watersheds from Scenic Viewshed to Experimental Forest, and converting a large area of Remote Recreation LUD north of Juneau to Semi-Remote Recreation.

Alternative 4 would have an estimated suitable forest land base of 999,000 acres and an ASQ of 360 MMBF by the second decade. This alternative would approximately correspond with Scenario 4 (high integrated industry) of the Brackley et al. (2006a) timber demand study. It is similar to Alternative 6 of the 1997 Final EIS.

Alternative 5

This is the No-Action alternative. It represents a continuation of the current Forest Plan and would result in a mix of national forest uses and activities. Timber would be managed in an area more extensive than under Alternative 3, but less extensive than under Alternative 4. The vast majority of current roadless areas would remain in a natural condition; however, the majority of roadless areas that contain substantial POG, outside of wilderness, could be partially developed. A total of 3.6 million acres of the Tongass would be in development LUDs and 13.2 million acres would be in non-development LUDs. This alternative is the same as the current Forest Plan (Alternative 11 from the 1997 Final EIS plus amendments).

Alternative 5 would have an estimated suitable forest land base of 757,000 acres and an ASQ of 267 MMBF. This alternative is the same as the 1997 Forest Plan, as amended (Alternative 11 from the 1997 Final EIS plus amendments).

Alternative 6

This is the Proposed Action alternative. It is very similar to the Alternative 5 (No Action) alternative in terms of LUD allocations; however, it includes extensive refinements to the boundaries of the small Old-Growth Reserves (based on a recently completed interagency evaluation), new Geologic Special Interest Areas, a new Experimental Forest, the conversion of a large area of Remote Recreation LUD north of Juneau to Semi-Remote Recreation, and other minor LUD refinements. Timber would be managed in an area more extensive than under Alternative 3, but less extensive than under Alternative 4. The vast majority of current roadless areas would remain in a natural condition; however, the majority of roadless areas that contain substantial POG, outside of wilderness, could be partially developed. A total of 3.5 million acres of the Tongass would be in development LUDs and 13.3 million acres would be in non-development LUDs. Specific LUD changes under this alternative would include the addition and modification of a number of Geologic Special Interest Areas, recommendations to change the Young Bay Experimental Forest to Semi-remote Recreation and the Cowee-Davies Creek watersheds from Scenic Viewshed to Experimental Forest, and converting a large area of Remote Recreation LUD north of Juneau to Semi-Remote Recreation. It also would include extensive refinements to the boundaries of the small Old-Growth Reserves, based on a recently completed interagency evaluation.

Alternative 6 would have an estimated 775,000 acres of lands suitable for timber production and an ASQ of 267 MMBF. This alternative is similar to Alternative 11 of the 1997 Final EIS.

Alternative 7

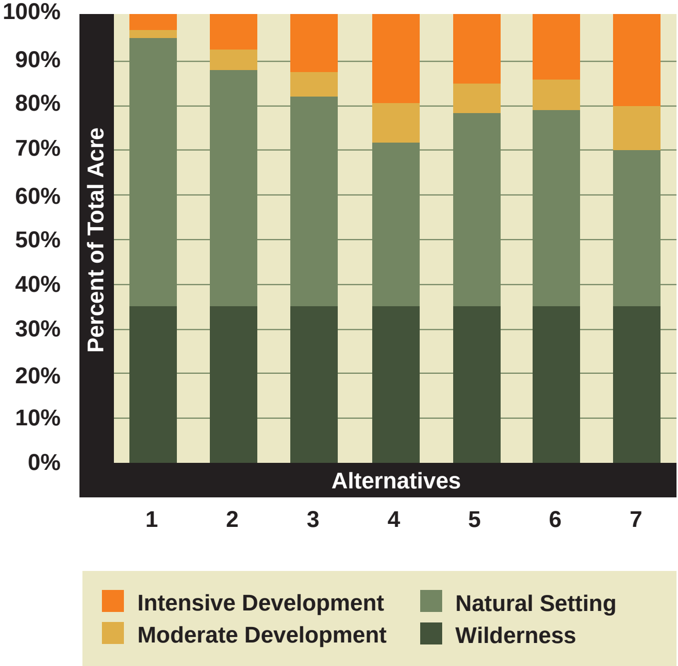
Under Alternative 7, forest management would provide a mix of national forest uses and activities, but would give much additional emphasis to timber management, relative to the current Forest Plan. Timber would be managed on a considerably expanded land base compared with the current Forest Plan. The vast majority of current roadless areas would remain in a natural condition; however, the majority of roadless areas that contain substantial POG, outside of wilderness, could be developed. A total of 5.0 million acres of the Tongass would be in development LUDs and 11.7 million acres would be in non-development LUDs. Almost all areas identified as development LUDs in Alternative 5 would also be development LUDs in this alternative, in addition to other areas. Specific LUD changes under this alternative would include the addition and modification of a number of Geologic Special Interest Areas and recommendations to change the Young Bay Experimental Forest to Semi-Remote Recreation and the Cowee-Davies Creek watersheds from Scenic Viewshed to Experimental Forest.

Alternative 7 would have an estimated suitable forest land base of 1,174,000 acres and an ASQ of 421 MMBF. This alternative is similar to Alternative 2 of the 1997 Final EIS.

Comparison of the Alternatives

This section briefly compares the environmental consequences of the seven alternatives with respect to the key issues described above. Prior to presenting the effects comparison, Figure 1 is displayed to help the reader compare the differences among the alternatives. It summarizes the LUD allocations of the alternatives using LUD Group combinations. The four LUD Groups combine the individual LUDs in terms of similarities in management.

Figure 1. Land Use Designation Group Comparison



Key Issue 1 – Protection of high value roadless areas from road development and timber harvest activity on the Tongass is of local and national importance, particularly for wildlife and biodiversity, recreation, and tourism.

The Tongass includes very large undeveloped land areas, with several portions of the Forest consisting of contiguous roadless areas that exceed 1 million acres and represent large, unfragmented blocks of wildlife habitat. This scale of roadless lands is not available elsewhere in the NFS, except on the Chugach National Forest. Roadless areas are considered important because of their wildlife habitat and recreation values and their importance for tourism. They are also important because of the passive use values and ecosystem services values they provide.

Direct Effects on Roadless Areas

The Tongass National Forest is about 91 percent roadless, including wilderness. Only small areas where communities are located, or where road construction and timber harvest have occurred, are “developed” to any noticeable degree. Developed areas and small unroaded areas (not included in inventoried roadless areas) cover about 1.51 million acres, or about 9 percent of the Tongass; wilderness covers about 5.75 million acres, or about 34 percent; and inventoried roadless areas (outside of wilderness) cover about 9.51 million acres, or about 57 percent. The maximum long-term reduction in roadless plus wilderness acreage on the Tongass and for all of Southeast Alaska (all Alaska lands southeast of Yakutat Bay) under each alternative are discussed in the following paragraphs and the alternatives are compared in Figure 2.

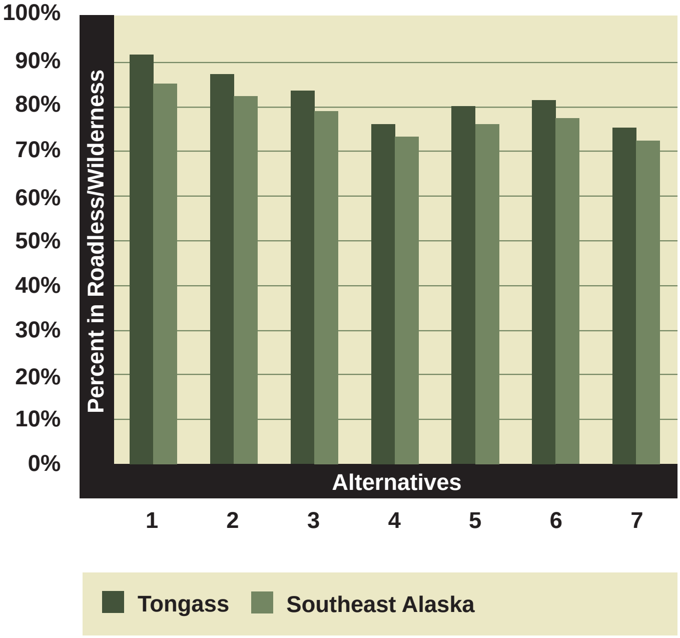
Alternative 1 is designed to avoid inventoried roadless areas and, because of this, after 100+ years of maximum implementation, 91 percent of the Tongass and 85 percent of Southeast Alaska would still be in roadless areas or wilderness.

Alternatives 2 and 3 would progressively enter more roadless areas with 0.8 million acres and 1.7 million acres of development LUDs in roadless areas, respectively. Alternative 2 would ultimately result in 87 percent of the Tongass and 82 percent of Southeast Alaska in roadless or wilderness and Alternative 3 would result in 83 percent and 79 percent.

Next in progression into roadless areas, Alternatives 5 and 6 would include 2.4 and 2.3 million acres of development LUDs in roadless, respectively. Alternative 5 would ultimately result in 80 percent of the Tongass and 76 percent of Southeast Alaska being in roadless or wilderness. These percentages would be 81 and 77 for Alternative 6.

Finally, Alternatives 4 and 7 both enter roadless areas to a higher degree. Alternative 4 would have 3.4 million acres of development LUDs in roadless and Alternative 7 would have 3.7 million. After 100 years or more of implementation, Alternative 4 would result in 76 percent of the Tongass and 73 percent of Southeast Alaska, and Alternative 7 would result in 75 percent of the Tongass and 72 percent of Southeast Alaska continuing as roadless or in wilderness.

Figure 2. Percent of the Tongass and Southeast Alaska in Roadless/Wilderness after 100+ Years



Distribution of Roadless Areas

Significant acreages of roadless areas would remain in all biogeographic provinces under all alternatives; however, some would maintain a higher percentage than others. Under Alternatives 1 and 2, none of the 21 biogeographic provinces within the Tongass boundary would have less than 50 percent of their areas in non-development LUDs. Alternative 1 would have 17 of the 21 provinces containing 90 percent or more acreage in non-development LUDs and Alternative 2 would have 13 provinces.

Alternative 3 would have 2 biogeographic provinces and Alternatives 5 and 6 would have 3 provinces with less than 50 percent in non-development LUDs. Alternative 3 would have 9 of the 21 provinces containing 90 percent or more of their acreage in non-development LUDs and Alternatives 5 and 6 would have 6 provinces.

Alternatives 4 and 7 would each result in 5 biogeographic provinces with less than 50 percent in non-development LUDs. These alternatives would have 6 of the 21 provinces containing 90 percent or more of their acreage in non-development LUDs.

Key Issue 2 – The Tongass National Forest needs to provide a sufficient timber supply to meet the market demand and help maintain a vibrant economy in Southeast Alaska.

Timber from the Tongass National Forest is the main source of raw materials for the region's wood products industry.

Demand may be thought of as the different amounts of a product that buyers are willing to purchase at different prices. Demand is not a single number, but instead a series of price-quantity relationships. The same is true of supply. It is the combination of supply and demand that determines the quantity and price of goods produced and consumed.

Accurately projecting future demand is difficult. Market demand for Southeast Alaska timber and wood products depends upon numerous, difficult to predict, factors, including changes in technology, growth and exchange rates in key markets, changes in consumer tastes and preferences, as well as developments in other producing regions whose products compete with those of Alaska.

The average timber sale on the Tongass includes spruce, hemlock, and cedar and results in a variety of log grades and species. In most forested conditions, the tree species, tree sizes, and tree quality are all mixed together. When a timber sale is purchased, the buyer is usually required to purchase all of the volume in that sale regardless of the composition. At present, none of the purchasers is set up to efficiently process all grades and species from such sales, nor is the local industry set up to process all of the components of the timber sales. In the absence of a facility to use utility and lower grade logs, a timber sale must be sustained solely on the profits made from the higher grade sawlogs, even though the operator must harvest and pay for the lower grade logs.

It should be noted that the Alaska Regional Forester (Region 10) signed a new policy in March 2007 that approved limited interstate shipments of unprocessed Sitka spruce and western hemlock. This policy is expected to increase the utilization of timber harvested on the Tongass and improve overall timber sale economics by providing a market for smaller diameter and low-grade material that cannot be processed profitably by sawmills in Southeast Alaska.

The wood products analysis prepared for this EIS is divided into long- and short-term effects. The long-term effects analysis evaluates the alternatives with respect to a) the projections developed by the Pacific Northwest Research Station of the Forest Service, and b) current production levels, installed capacity, and the minimum volumes required by various processing facilities. These benchmarks are used to evaluate the long-term effects of the alternatives. Long-term effects are assessed based on the ASQ projected under each alternative.

The short-term effects analysis discusses three key components of the "timber pipeline:" volume under contract, NEPA-cleared volume (i.e., sales that have approved NEPA documents but have not yet been sold), and timber volume in preparation (i.e., proposed sales that are currently being evaluated under the NEPA process).

Long-Term Effects

Pacific Northwest Research Station Projections. The Forest Service commissioned the Pacific Northwest Research Station to develop a series of demand projections. This resulted in a "derived demand" analysis that projected various demand figures for four scenarios based upon differing assumptions about future markets and future processing facilities in Southeast Alaska (Brackley et al. 2006a). These future visions of the Southeast Alaska wood products industry are hypothetical and are used in this EIS to illustrate the type of developments that might take place in cases where different volumes are made available for harvest. The transition from one scenario to the next involves new private investment and market development. A key factor in attracting new investment is whether or not a supply of timber “shelf volume” is available for purchase.

Alternatives 1 through 4 were designed to correspond with timber demand Scenarios 1 through 4, respectively, while also responding to other concerns. The discrepancy between the second decade ASQs for Alternatives 1 and 2 and projected demand for 2022 under Scenarios 1 and 2 reflects these other concerns. These scenarios are briefly summarized in the following paragraphs, along with the ability of the alternatives to meet each scenario in 2022.

Scenario 1 – Limited Lumber Production. This scenario approximates the status of the timber industry in Southeast Alaska at the time that the Brackley et al. study was completed. Total derived demand is projected to be 68 MMBF in 2022 under this scenario. It is likely that this volume would be primarily logs from more economical (non-interchangeable component [NIC I]) lands.

> **Alternative 1**, with a projected total output of 49 MMBF, could not provide sufficient volume to meet this scenario, as currently modeled.
>
> **Alternatives 2, 3, 4, 5, 6, and 7** could all provide sufficient volume to meet this scenario in 2022.

Scenario 2 – Expanded Lumber Production. This scenario also projects that only higher value logs are processed, with limited new investments in the existing mills in Southeast Alaska. Total derived demand is projected to be 187 MMBF in 2022 under this scenario. As in Scenario 1, it is likely that this volume would be primarily higher value logs from the more economical (NIC I) lands.

> **Alternatives 1 and 2**, with projected total outputs of 49 MMBF and 151 MMBF, could not provide sufficient volume to meet this scenario.
>
> **Alternatives 3, 4, 5, 6, and 7** could all provide sufficient volume to meet this scenario.

Scenario 3 – Medium Integrated Industry. This scenario builds on Scenario 2 and would establish processing capacity to fully utilize sawlogs and low grade and utility logs from federal and state timber sales. Under this scenario the current sawlog milling capacity would operate efficiently and new processing capacity would be developed to utilize the material that has formerly been left in the woods or exported. Total derived demand is projected to be 204 MMBF in 2022 under this scenario.

Alternatives 1 and 2, with projected total outputs of 49 MMBF and 151 MMBF, respectively, could not provide sufficient volume to meet this scenario.

Alternatives 3, 4, 5, 6, and 7 could provide sufficient volume to meet this scenario.

Scenario 4 – High Integrated Industry. This scenario builds on Scenario 3 and provides an estimate of the upper market level for the foreseeable future. In order for this situation to be realized, new investments in processing capacity would need to be made and additional market shares established. Total derived demand is projected to be 342 MMBF in 2022 under this scenario.

Alternatives 1, 2, 3, 5 and 6, with projected total outputs of 49 MMBF, 151 MMBF, 205 MMBF, 267 MMBF, and 267 MMBF, respectively, could not provide sufficient volume to meet this scenario.

Alternatives 4 and 7 could provide sufficient volume to meet this scenario.

Current Production Levels, Installed Capacity and Minimum Volumes Required by Various Processing Facilities. The existing mills in Southeast Alaska had an estimated active installed processing capacity of 261 MMBF in 2006 and a total processing capacity of 361 MMBF. The estimated NIC I components of the harvest volumes projected under each alternative range from 9 percent of the active installed processing capacity under Alternative 1 to 71 percent under Alternative 7. The NIC I volume projected under Alternative 5 (No Action) represents about 46 percent of the existing active processing capacity. The projected NIC I components represent smaller shares of the total installed capacity, ranging from 7 percent under Alternative 1 to 51 percent under Alternative 7.

Two of the future demand scenarios evaluated by Brackley et al. (2006a) involve an integrated industry. These scenarios are based on the assumption that as stable volumes get higher, the industry will develop in an integrated fashion, with operations and production that utilize materials that are inefficient or excess to one another's production. The potential components of an integrated industry could include sawmills, a veneer plant, and a medium density fiberboard (MDF) or bioenergy facility, among others. The different facilities would process different types of log. Sawmills would generally process higher quality material (high grade sawlogs), with the other types of facility processing lower quality material (low grade sawlogs and utility logs).

Based on the projected harvest volumes, only Alternatives 4 and 7 would provide sufficient volume to support an integrated industry that consisted of the existing sawmills, a veneer plant, and an MDF or Bioenergy facility. Under Alternative 5 (No Action), there would be sufficient volume to support the existing sawmills. There would also be sufficient volume to support one or more veneer plants or an MDF or other chip-related operation, but not both.

A number of timber projections were reviewed as part of this analysis. Based on this review, the Forest Service identified a potential upper planning cycle demand of 360 MMBF from all sources. Only Alternative 7 includes sufficient volume to meet this level of demand only from NFS acres.

Direct Employment and Income. Direct sawmill and logging employment estimates are presented in job-years, which represent the equivalent of one year's employment. This potential employment would not necessarily occur all in one year and estimated job totals do not directly translate into estimated numbers of affected workers. These estimates assume a linear relationship between harvest and employment levels, with a 1 percent change in harvest resulting in a 1 percent change in employment. In reality, changes in volume will have a lagged response in employment, but the assumed linear relationship is an approximation that can be used to compare alternatives.

Based on projected harvest volumes, average annual direct wood products employment would range from 494 annualized jobs under Alternative 1 to 1,922 jobs under Alternative 7. Approximately 274 of these annualized jobs would be associated with non-Tongass harvest under each alternative. Viewed in relation to Alternative 5

(No Action), projected direct employment would range from a 63 percent decrease under Alternative 1 to an increase of approximately 43 percent under Alternative 7.

Projected annual direct income, which is calculated based on the projected number of jobs, would range from $19.5 million under Alternative 1 to $72.5 million under Alternative 7. These totals also include income that would be generated by non-Tongass harvest.

Short-Term Effects

The following discussion provides an indication of potential short-term effects. Actual effects would depend on the volumes in each pool when the decision is implemented. In the case of the volume under contract, potential impacts would also depend on whether potentially affected sales were cancelled or exempted as part of the decision.

Volume under Contract. Alternative 1 would maintain the majority of the Inventoried Roadless Areas on the Tongass in a natural condition and would not allow timber harvest in those areas. Alternative 1 would affect 52 percent (54 MMBF) of the volume under contract as of August 2006 (104 MMBF). The volume currently under contract would not be affected by any of the other alternatives.

NEPA-Cleared Volume. Alternative 1 would affect 56 percent (255 MMBF) of the current NEPA-cleared volume as of August 2006 (454 MMBF). It should be noted that not all this volume is considered economic under current market conditions. Alternative 2 would affect 44 percent or 198 MMBF of this volume, which represents the volume that has passed through the NEPA process and is scheduled to be available for sale in the near future. None of the other alternatives would affect this volume.

Timber Volume in Preparation. Alternative 1 would affect 56 percent (298 MMBF) of the timber volume in preparation as of September 2006 (536 MMBF). Alternatives 2 and 3 would each affect approximately 7 percent or 40 MMBF of this volume and Alternatives 4, 5, 6, and 7 would not affect this volume.

Key Issue 3 – Protection of wildlife habitat and biodiversity on the Tongass is of local and national significance and is affected by road development and timber harvest activities.

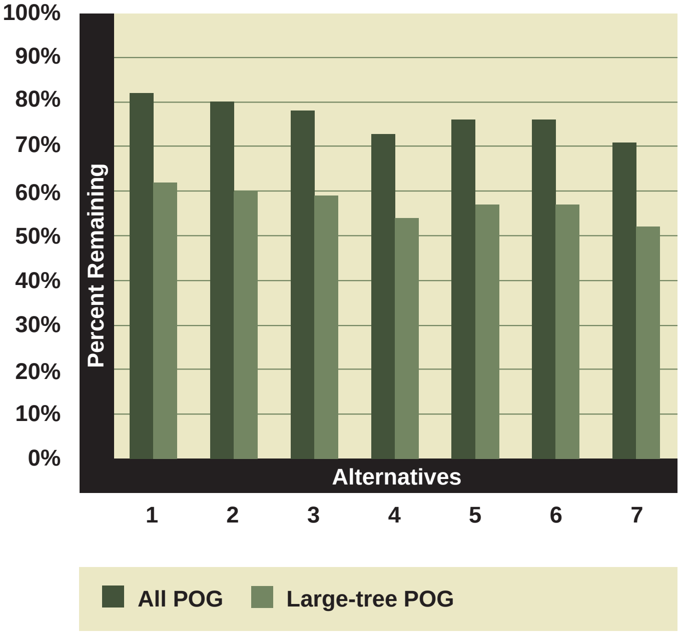
The Tongass National Forest supports a unique and important assemblage of wildlife including the largest population of brown bears and breeding bald eagles in the world, species of high importance for subsistence (e.g., Sitka black-tailed deer), an extensive array of endemic mammals and other species, and a large number of species that are at least partially dependent on old-growth habitats (e.g., marten and goshawk). Populations of many of these species and the biodiversity of Southeast Alaska are affected by timber harvest and the development of roads.

Old-Growth Harvest

The amount of productive old growth (POG) harvest is a key indicator of effects on many species, including goshawks, marten, endemic mammals, and deer. The range of old-growth harvest is wide among the alternatives. Alternative 1 has the lowest maximum harvest of POG at 86,000 acres, while Alternative 7 has the highest maximum at 807,000 acres. After 100 years or so, a minimum of 90 percent of the original POG on NFS lands would remain under Alternative 1 and 77 percent would remain under Alternative 7. Percentages for all of Southeast Alaska, including non-NFS lands, would be 82 percent for Alternative 1 and 71 percent for Alternative 7. The other five alternatives would rank between Alternatives 1 and 7; their order from lowest to highest harvest would have Alternative 2 at the low end progressing to Alternative 3, then 6, then 5, and then 4.

For large-tree POG after 100+ years, a minimum of 78 percent of the original amount would remain on the Tongass under Alternative 1 and 64 percent would remain under Alternative 7. Percentages for all of Southeast Alaska, including non-NFS lands, would be 62 percent for Alternative 1 and 52 percent for Alternative 7. Figure 3 compares the percentages for all POG and large-tree POG for all of Southeast Alaska, by alternative.

Figure 3. Minimum Percent of Original POG and Original Large-tree POG Remaining in 100+ Years in All of Southeast Alaska



Road Development

The Tongass currently has 4,941 miles of existing roads (including closed and non-system roads). This total includes 2,619 miles of open roads, plus 913 miles of closed roads that are in storage and 1,409 miles of non-system roads. Road construction can negatively affect wildlife by eliminating habitats and by permitting increased access, which can result in larger harvests and more human-large predator interactions.

Under Alternative 1, an estimated maximum of 774 new road miles would be developed over 100 years. For Alternatives 2 and 3 the estimated maximum new road construction would be 2,079 and 2,799 miles, respectively. The majority of these road miles would be closed after harvest activities are completed, and reopened at the next entry. The maximum road miles to be constructed under Alternatives 5 and 6 would be 3,874 and 3,744, respectively. Alternative 4 would construct a maximum of 4,890 miles of new road and Alternative 7 would construct a maximum of 5,825 miles of new road.

A useful indicator of road effects on wildlife is the road density within Wildlife Analysis Areas (WAA). On Tongass NFS lands, 8 percent of the WAAs that make up the Tongass have a road density greater than 1.0 mile per square mile under existing conditions. Road density would increase in many areas after 100+ years of implementation of the alternatives. Under Alternative 1, the density would increase so that a maximum of 11 percent of the WAAs would have a density greater than 1.0 mile per square mile. Alternatives 2, 3, and 6 would have a maximum of 16 to 18 percent, Alternative 5 would have a maximum of 19 percent, and Alternatives 4 and 7 would have 23 to 25 percent. These percentages would increase further when cumulative road development, including future road development on non-NFS lands, is considered. The percentage of WAAs with road density on all lands (including non-NFS lands) greater than 1.0 mile per square mile would be 20 percent for Alternative 1, 23 to 26 percent for Alternatives 2, 3, 5, and 6, and 28 to 31 percent for Alternatives 4 and 7.

Representation of Old-Growth Forests

The percentage of POG remaining in each biogeographic province is an indication of the degree to which all potentially valuable ecological communities remain fully represented.

After 100 years of Alternative 1 implementation, 19 of the 23 biogeographic provinces covering Southeast Alaska would have 75 percent or more of their POG remaining and none would have less than 50 percent (minimum value = 55 percent). For large-tree POG, 16 out of 23 provinces would have at least 50 percent of the original amount remaining (minimum value = 32%).

At the other end of the spectrum, after 100 years of implementation of Alternatives 4 or 7, 11 to 12 of the 23 biogeographic provinces would have 75 percent or more of their POG remaining and one would have less than 50 percent (minimum value = 44 percent for Alternative 7). Considering large-tree POG, 13 to 14 of the provinces would have at least 50 percent of the original amount remaining (minimum value = 29 percent under Alternative 7).

The other four alternatives (Alternatives 2, 3, 5, and 6) would all have values within these ranges; they would have 13 to 18 of the 23 biogeographic provinces covering Southeast Alaska with 75 percent or more of their POG remaining. None of these alternatives would have any biogeographic provinces with less than 50 percent of their POG. Each of them would also have 16 out of 23 provinces with least 50 percent of the original large-tree POG remaining (minimum value = 31%).

Conservation Strategy and Landscape Connectivity

An adequate amount and distribution of high quality old-growth blocks with good landscape connectivity is fundamental to the "coarse filter" aspect of the Old-Growth Forest Conservation Strategy and is important for the maintenance of viable, well-distributed populations of many species of wildlife. Because of the spacing of old-growth reserves and other non-development LUDs, Alternatives 1 and 2 would result in a good to excellent distribution of high quality old-growth blocks over the long term, and would have little to no effects on landscape "pinch-points." Alternatives 3, 5, and 6 would have good to very good spacing of old-growth reserves and other non-development LUDs and would similarly affect only one "pinch-point."

Under Alternative 4, the long-term result would be a good distribution of high quality old-growth blocks in the four biogeographic provinces with old-growth reserves, but a poor to fair distribution in the other provinces over the long term. The old-growth retention requirement would mitigate this to some degree, but would not necessarily result in blocks or large patches of POG being retained. This alternative would also negatively affect three critical landscape "pinch-points."

Alternative 7 would result in a poor distribution of high quality old-growth blocks over the long term throughout most of the Tongass because of the lack of old-growth reserves, the lack of an old-growth retention requirement, and the high acreage of development LUDs.

It would negatively affect four critical landscape "pinch-points" and result in a lower degree of landscape connectivity due to narrower beach buffers.

Species-Specific Effects

Expert panel viability assessments were conducted for key species to rate the alternatives considered in the 1997 Forest Plan Revision EIS. These ratings were transferred to the alternatives in this EIS, based on the four alternatives that are similar between EISs (i.e., 1997-Alternative 6 is similar to 2007-Alternative 4, 1997- Alternative 11 is similar to 2007-Alternatives 5 and 6, and 1997-Alternative 2 is similar to 2007-Alternative 7), and based on harvest acreage similarities. The ratings were also transferred into a relative qualitative description of the likelihood of maintaining viable, well-distributed populations so that the alternatives could more easily be compared.

Under Alternative 1, the likelihood of maintaining viable, well-distributed populations on the Tongass after 100 years is estimated to be very high for the goshawk, marten, wolf, and brown bear, and moderate for endemic mammals. Alternative 2 would rate almost as high. Under Alternative 3, this likelihood is estimated to be very high for the goshawk; high for the marten, wolf, and brown bear; and moderate for endemic mammals.

Alternatives 5 and 6 would have similar ratings. The likelihood of maintaining viable, well-distributed populations on the Tongass after 100 years is estimated to be high for the goshawk, wolf and brown bear; and moderate for the marten and endemic mammals.

Alternatives 4 and 7 rate the lowest among the alternatives. For Alternative 4, the likelihood of maintaining viable, well distributed populations on the Tongass after 100 years is estimated to be high for the wolf; moderately high for the goshawk and brown bear; moderate for the marten; and moderately low for endemic mammals. For Alternative 7, the likelihood is estimated to be moderately high for the wolf and brown bear; moderate for the goshawk and marten; and very low for endemic mammals.

Deer habitat capability expressed in terms of percent of 1954 values can be used to identify the amount of habitat change over time (current habitat capability = 88 percent of 1954 value, based on the deer model). After 100 years of Forest Plan implementation, the percentage for Alternative 1 could drop as low as 86 percent, 84 percent under Alternative 2, 83 percent under Alternative 3, 82 percent under Alternative 6, 81 percent under Alternative 5, 79 percent under Alternative 4, and 77 percent under Alternative 7. These percentages could be increased somewhat with more intensive management of young-growth forests.

Abstract:

A Ninth Circuit Court ruling (2005) and the 5-Year Forest Plan Review (completed in January 2005) indicated the need to consider amending the Tongass National Forest Land and Resource Management Plan. This Final EIS responds to the Court and the 5-Year Review by analyzing seven alternatives for amending the Plan, including the No-Action alternative. Maps accompanying this Final EIS depict the land use designations proposed under each alternative. A separate document, called the Proposed Land and Resource Management Plan (Forest Plan), was published with the Draft EIS and was revised, as indicated in Chapter 2 of this Final EIS, to represent the Final Proposed Forest Plan. The action alternatives incorporate this Final Proposed Plan entirely, or with modifications. A number of issues are addressed, but three key issues are identified: 1) protecting high-value roadless areas from road development and timber harvest activity in order to protect roadless area values; 2) providing a sufficient timber supply to meet the market demand and help maintain a vibrant economy in Southeast Alaska; and 3) protecting the wildlife habitat and biodiversity of the Tongass, which is affected by road development and timber harvest activities. The seven alternatives are designed to provide a range of options for addressing these issues. Direct, indirect, and cumulative effects of the alternatives are quantified and compared in Chapters 2 and 3, based on inventory data and modeling.

CHAPTER 1
PURPOSE AND NEED

Purpose and Need

Introduction

Forest land and resource management planning is a process for developing, amending, and revising land and resource management plans for each of the National Forests in the National Forest System (NFS). Forest plans are required by the National Forest Management Act of 1976 (NFMA). The 16.8-million-acre Tongass National Forest was the first forest to complete a Land and Resource Management Plan (Forest Plan or Plan) under the NFMA in 1979. The original Forest Plan was amended in 1986 and 1991 and revised in 1997. A Supplemental Environmental Impact Statement (SEIS) was completed in 2003, which further evaluated roadless areas for their wilderness potential. The revised Plan has been amended 24 times since 1997, primarily to adjust Old-Growth Habitat Reserve boundaries and for electronic/communication site designation.

A recent Ninth Circuit Court ruling (2005) and the 5-Year Plan Review (completed in January 2005) indicated the need to amend the current Tongass National Forest Land and Resource Management Plan. This Final EIS responds to the Court and the 5-Year Review by thoroughly analyzing six alternatives for amending the Plan in addition to the No-Action Alternative (Alternative 5). The analysis is being published in two volumes: the first volume contains the main EIS, and the second volume contains the appendices to the EIS. A separate document titled Land and Resource Management Plan (Forest Plan or Plan) is also being published and represents the complete Forest Plan including all amendments. This document represents the Forest Plan that is used in all alternatives, except for differences that are outlined in Chapter 2. Finally, the Record of Decision (ROD), describing the decision and rationale for that decision, is also being published.

This EIS analyzes a possible amendment to the current Forest Plan and is tiered to the 1997 Tongass Land Management Plan Revision EIS and the 2003 Supplemental EIS for Roadless Area Evaluation for Wilderness Recommendations.

Forest Planning History on the Tongass National Forest

NFMA, passed in 1976, required each national forest to develop a land and resource management plan and revise its plan every 10 to 15 years. The Tongass became the first forest to complete a Forest Plan under NFMA in April 1979. The Alaska National Interest Lands Conservation Act (ANILCA) passed December 2, 1980. The 1979 Forest Plan was amended in 1986, reflecting changes mandated by ANILCA. The Forest Plan revision process began in 1987 and a Draft EIS was published in June 1990. In November 1990, the Tongass Timber Reform Act (TTRA) was passed. The Forest Plan was amended in February 1991 to incorporate the TTRA changes. The Forest Plan Revision process continued with a Supplement to the Draft EIS published in September 1991, which incorporated all changes required by TTRA and evaluated a new set of alternatives. Because Congress had just acted on the wilderness issue following completion of the June 1990 Draft EIS, the Forest Service did not reconsider roadless areas for potential wilderness recommendation. The Forest Service prepared a Final EIS in the fall of 1992, but did not publish an associated Record of Decision (ROD). The Regional Forester found there was new information that should be collected to respond to 36 CFR 219.19. That process led to the 1997 Final EIS and the Forest Plan Revision ROD (1997 ROD).

The 1997 Forest Plan was the subject of 33 separate appeals by organizations and individuals. In 1999, the Under Secretary of Agriculture affirmed the Regional Forester's decision regarding all 33 appeals, based on the 1997 Tongass Forest Plan Revision Final EIS and planning record. The Under Secretary also issued a new ROD (1999 ROD) for the 1997 Tongass Land Management Plan Revision.

1 Purpose and Need

Two lawsuits challenged the 1997 and 1999 RODs in the U.S. District Court for the District of Alaska. The Alaska Forest Association and some Southeast Alaska communities challenged many aspects of the 1997 Plan and the process by which the 1999 ROD was issued. The Sierra Club and other environmental groups challenged the lack of wilderness area consideration and potential recommendations in the 1997 Plan Revision, FEIS and ROD. The Court issued a single opinion for both cases in March 2001.

In the Alaska Forest Association case *(Alaska Forest Ass'n v. United States Dep't of Agric.* No. J99-0013 CV [JKS] [D. Alaska]), the U.S. District Court upheld the 1997 ROD against all challenges, but held that the 1999 ROD was not properly adopted. The Court vacated the 1999 ROD and enjoined the Forest Service from implementation. The Court further directed the Forest Service to prepare an SEIS addressing the changes from the 1997 Tongass Forest Plan. Because of the extensive public involvement and scientific review in the 1997 ROD, and its thorough policy and legal review of the administrative appeal process and by the District Court, the Forest Service did not propose changes to the 1997 ROD similar to those enjoined by the District Court.

In the Sierra Club challenge of the 1997 Tongass Forest Plan Revision FEIS (*Sierra Club v. Lyons*, No. J00-0009 CV [JKS] [D. Alaska]), the Ninth Circuit Court found the 1997 Tongass Forest Plan should have considered making wilderness recommendations in the Final EIS. The Court ordered the Forest Service to prepare an SEIS evaluating wilderness recommendations for roadless areas on the Tongass and provide the relative contribution to the National Wilderness Preservation System in its Analysis of the Management Situation. The Forest Service issued a Final SEIS and ROD for Roadless Area Evaluation for Wilderness Recommendations in February 2003.

The Natural Resources Defense Council (NRDC) filed a lawsuit (referred to as NRDC I) in the U.S. District Court of Alaska in December 2003 challenging the 1997 Forest Plan and six timber sales. In January they filed a separate lawsuit on a seventh timber sale (referred to as NRDC II) and another lawsuit challenging an eighth sale in March 2004 (referred to as NRDC III). The District Court upheld the 1997 Forest Plan and related National Environmental Policy Act (NEPA) documents on all claims in September 2004. NRDC appealed this ruling to the Ninth Circuit Court of Appeals. The Ninth Circuit Court issued a ruling on NRDC I and NRDC II in August 2005. It found inadequacies primarily relating to the NEPA process for the 1997 Forest Plan. These inadequacies dealt with the timber demand estimates, the range of alternatives related to timber demand, and the cumulative effects analysis related to activities on non-NFS lands. While this process was taking place, the Forest completed a 5-Year Review of the Forest Plan. This review identified a number of items that could lead to adjustments to the Plan.

Purpose and Need

The purpose and need for this EIS is to respond to the Ninth Circuit Court's decision in *Natural Resources Defense Council vs. U.S. Forest Service* (421 F.3d 797, August 5, 2005). In that decision, the Court held that the EIS and ROD for the Forest Plan adopted in 1997 had errors relating to the use of projected market demand for timber, the range of alternatives considered relative to the market demand calculations, and the cumulative effects of activities on non-NFS lands. In addition, there is a need to consider adjustments to the Plan based on information generated during the recent 5-Year Review of the Forest Plan. Therefore, the purpose and need for this EIS primarily relates to the August 2005 Court decision, the 5-Year Plan Review, and other minor clarifications and updates.

Forest Location and Description

The 16.8-million-acre Tongass National Forest (Tongass or Forest) occupies about 7 percent of the area of Alaska. The Tongass is located in the southeastern portion of the state (the area commonly called the panhandle of Alaska or Southeast Alaska) and extends from Dixon Entrance in the south to Yakutat Bay in the north, and is bordered on the east by Canada and on the west by the Gulf of Alaska. The Tongass extends approximately 500 miles north to south and approximately 120 miles east to west at its widest point. Figure 1-1 is a vicinity map of the Forest.

The Tongass includes a narrow mainland strip of steep, rugged mountains and icefields and more than 1,000 offshore islands known as the Alexander Archipelago. Together, the islands and mainland have nearly 11,000 miles of meandering shoreline, with numerous bays and coves. A system of seaways separates the many islands and provides a protected waterway called the Inside Passage. Federal lands comprise about 95 percent of Southeast Alaska, with about 80 percent in the Tongass National Forest and most of the rest in Glacier Bay National Park and Preserve. The remaining land is held in state, Native corporations, and other private ownerships.

Most of the area of the Tongass is wild and undeveloped. Approximately 73,000 people inhabit Southeast Alaska, primarily in 32 communities located on islands or mainland coastal areas. Only eight of the communities have populations greater than 1,000 persons. Most of these communities are surrounded by, or adjacent to, NFS land. Only three communities are connected to other parts of the mainland by road: Haines and Skagway in the north, and Hyder in the southeast.

The economies of Southeast Alaska's communities rely on the Tongass National Forest to provide natural resources for uses such as fishing, timber harvesting, recreation, tourism, mining, and subsistence. Maintaining the abundant natural resources of the Forest, while providing opportunities for their use, is a major concern of Southeast Alaska residents.

Ranger District offices on the Tongass National Forest are located in Yakutat, Juneau, Hoonah, Sitka, Petersburg, Wrangell, Thorne Bay, Craig, and Ketchikan. There are also two National Monuments, Admiralty Island with an office in Juneau and Misty Fiords with an office in Ketchikan (Figure 1-1).

Public Issues

Identification of issues helps define or predict the resources or uses that could be most affected by the management of NFS lands. These issues are used as a basis to formulate management alternatives or to measure differences between alternatives.

Ten public issues were originally identified in 1988 for the Forest Plan Revision. These original issues included scenic quality, recreation, fish habitat, wildlife habitat, subsistence, timber harvest, roads, minerals, roadless areas, and local economy. The 1991 Forest Plan Revision Supplemental Draft EIS (SDEIS) added an additional concern, identifying and considering for recommendation potential wild, scenic, and recreational rivers.

After the release of the 1991 SDEIS, considerable new information pertaining to the Tongass Forest Plan Revision became available. Out of this information emerged five additional issues, determined by the Regional Forester to need more study and evaluation before a final revised Forest Plan could be adopted. Some of these issues were aspects or extensions of the ten public issues previously considered; others were new as issues or had not been considered as issues in themselves. The five issues were wildlife viability, fish habitat, karst and caves, alternatives to clearcutting, and socioeconomic considerations. These issues were assessed in the 1996 Revised SDEIS and the 1997 Tongass Forest Plan Revision Final EIS.

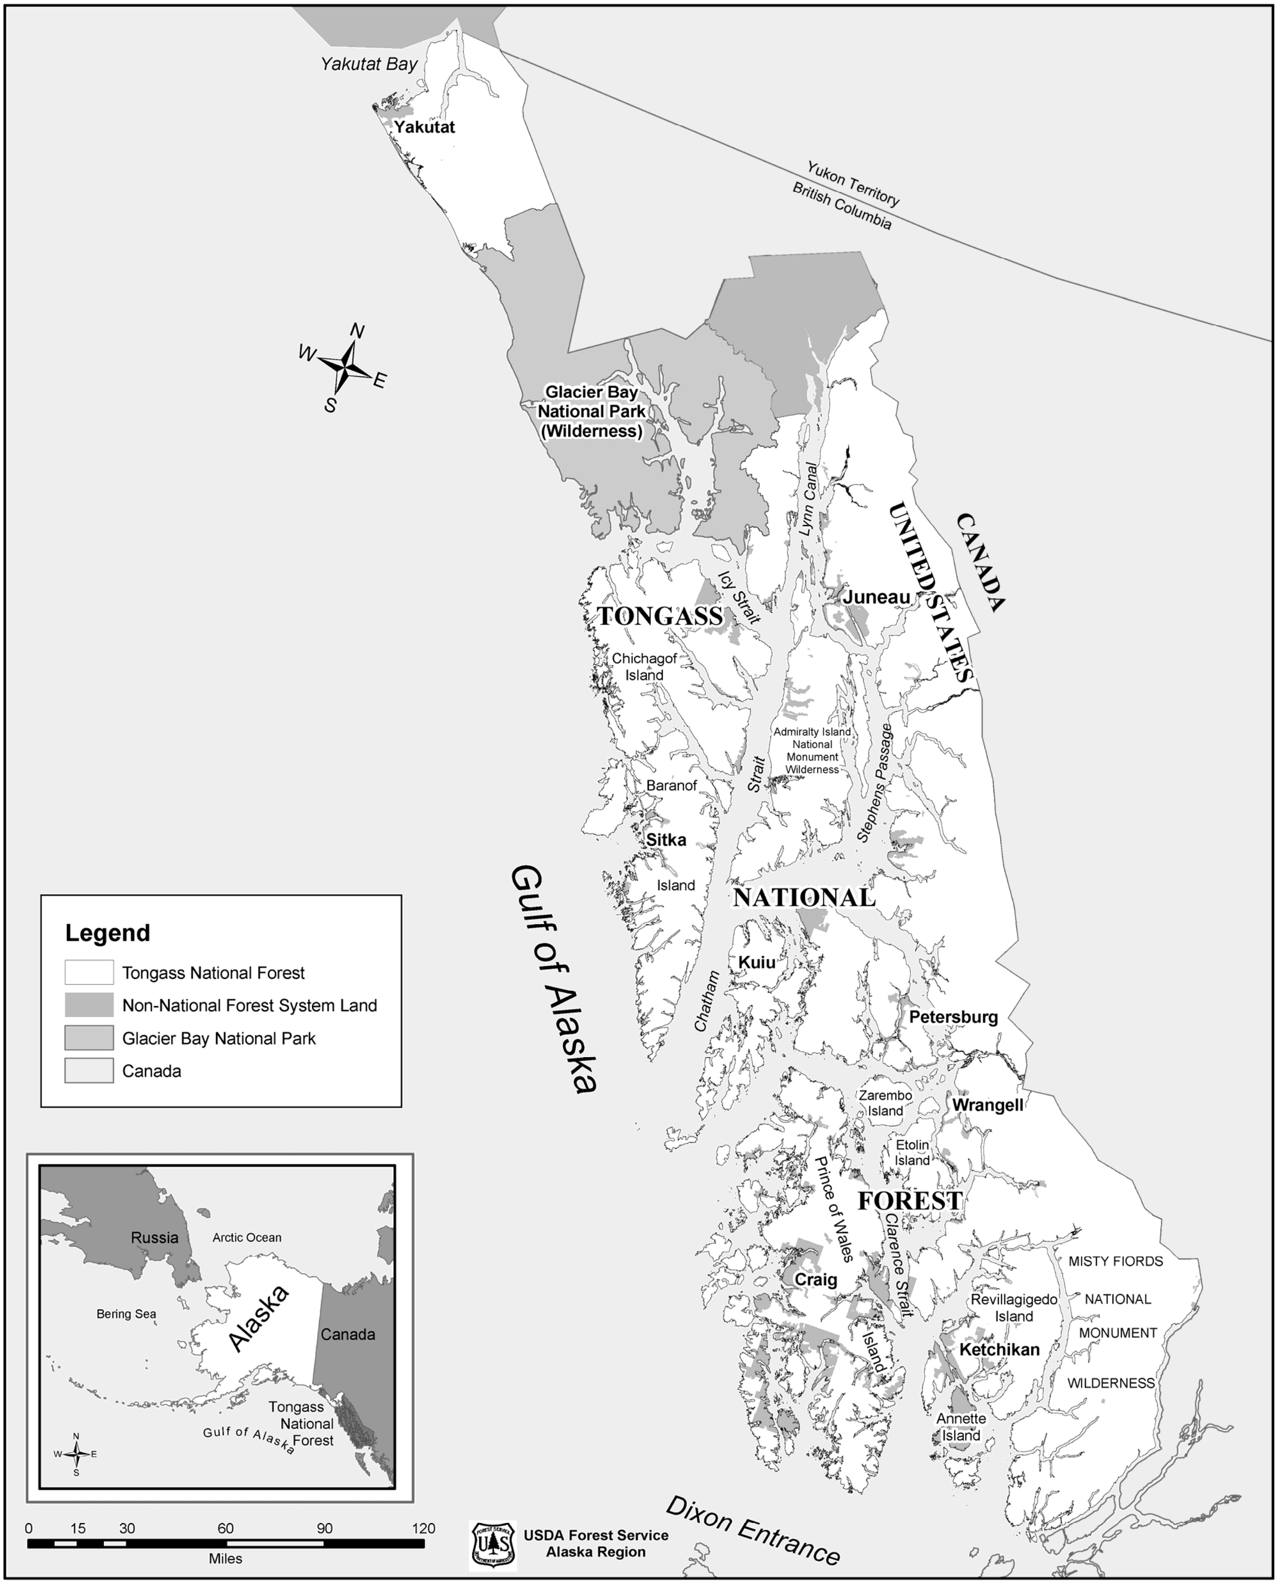

Figure 1-1.
Tongass National Forest Vicinity Map

The 2003 SEIS reviewed and evaluated roadless areas and analyzed alternative groupings of roadless areas for wilderness recommendations. Two broad issue categories, referred to as key issues, were identified as the major issues driving the alternatives of the SEIS analysis. They included 1) the long-term protection of roadless areas and associated values, and 2) the social and economic well-being of the communities of Southeast Alaska.

Public Input

The scope of <u>this</u> EIS was initially determined by the Court in its 2005 ruling, and by the 5-Year Review of the Forest Plan. Additional information was considered to help clearly define the issues and for use in the development and analysis of alternatives. For this Final EIS, comments and information from a wide variety of public input that related to amending the Forest Plan were considered. This information included the following:

- Public comments generated during the 1997 Tongass Forest Plan Revision process;
- Tongass Forest Plan Revision appeals;
- Public input specific to the Tongass National Forest on the Forest Service's 2001 National Roadless Area Conservation Rule;
- Public comments generated relative to the 2003 Supplemental EIS;
- Public input expressed during project-level NEPA analyses over the past 10 years or so; and
- Public input received in response to the Notice of Intent and the Web site for this EIS.

The planning record of the Tongass includes public input encompassing most of the last 2 decades. Of special note are the extensive public meetings held in Southeast Alaska for the 1997 Forest Plan Revision, the 2001 National Roadless Area Conservation Rule, and the 2003 SEIS.

In addition to the above, public involvement has occurred during the development of this EIS. Public involvement activities that have taken place during this time frame include the following:

- The Notice of Intent was published in the Federal Register in March 2006.
- A Forest Plan Adjustment Web site was developed in January 2006 and has been maintained to inform and engage the public since then. It is updated as new information is developed or published and provides a mechanism for public input. Several hundred comments and questions were received through the Web site or via emails associated with the Web site in the first few months of operation.
- A Weblog regarding the Forest Plan adjustment effort was established in July 2006 and was continually maintained as another method of public communication.
- In response to the above items, a number of letters were received containing comments regarding the issues and alternatives. These included letters from environmental organizations, the timber industry, Southeast Alaska community organizations, and a number of individuals from Southeast Alaska and across the nation.

- Government-to-government consultation has been conducted throughout the process, and is ongoing, with federally recognized Tribes.
- A number of group-specific meetings have also occurred with various organizations (including Alaska Native groups).
- A variety of news releases were issued relative to the Forest Plan adjustment throughout the process.
- A series of ongoing meetings, hosted by the National Forest Foundation and The Nature Conservancy, known as the Tongass Futures Roundtable, have resulted in considerable discussion of Tongass management issues among a broad spectrum of individuals and groups interested in the future of Southeast Alaska since May 2006.
- The input received prior to issuance of the Draft EIS was reviewed and a summary of this synthesis is presented as Appendix A (Issue Identification) to the Final EIS.
- A Draft EIS and Proposed Forest Plan were released on January 12, 2007. This began a 90-day comment period, which was later extended to 108 days. The comment period closed on April 30, 2007.
- During the comment period, open houses and public hearings were held in 24 Alaska communities. In addition to comments on the Draft EIS, the hearings provided opportunity to hear concerns related to subsistence and Alaska Native issues.
- On March 22, 2007, an open house and public hearing was held on the internet, to solicit public comment in an open forum from individuals living anywhere in the world.
- Over 84,000 comment documents were received, including individual letters, form letters, emails, hearing testimony, and comments submitted directly via the Forest Plan Adjustment Web site. Slightly more than 2,000 of these were classified as individual comment documents and the others were classified as form letters and emails. The individual comment documents were subdivided into approximately 5,500 individual comments. Responses were received from all 50 states and 89 foreign countries. A summary of the substantive comments and Forest Service responses to those comments can be found in Appendix H.

The Three Focus Issues

Key Issues

Any alternative that proposes to change the Forest Plan could affect resources and/or outputs relative to the current Forest Plan. Therefore, Chapter 3 of the EIS shows the effects of the various alternatives on all relevant resources and evaluates their effects relative to all of the issues and concerns previously identified during the 1997 plan revision process. However, based on the purpose and need of this EIS and the public input received during the current EIS process, some issues are more likely to influence the comparison among alternatives and represent the major issues to be evaluated. These issues were grouped into three broad issue categories, referred to as the key issues. These key issues are the major issues driving the alternatives and analyses.

Key Issue 1 – Protection of high value roadless areas from road development and timber harvest activity on the Tongass National Forest is of local and national importance, particularly for wildlife and biodiversity, recreation, and tourism.

Many people believe roadless areas should be allowed to evolve naturally through their own dynamic processes and should be afforded protection that ensures this will occur. The Tongass includes very large undeveloped land areas with several portions of the Forest consisting of contiguous roadless areas that exceed 1 million acres and represent large, unfragmented blocks of wildlife habitat. This large scale of roadless lands does not exist on any other National Forest, except the Chugach National Forest in Southcentral Alaska.

Roadless areas are considered important because of their wildlife habitat and recreation values and their importance for tourism. They are also important because of the passive-use and ecosystem services values they provide.

Passive-use values represent values that individuals assign to a resource independent of their use of that resource. Typically this includes existence, option, and bequest values, and represents the value individuals obtain from knowing that expansive roadless areas exist, knowing that they are available to visit in the future should they choose to do so, and knowing that they are available for future generations to inherit. There is interest in preserving large portions of the Tongass because so much of it is in a natural condition, unlike most other national forests, and because the Forest represents a significant portion of the world's remaining temperate rainforests.

Ecosystem services represent the services provided to society by healthy ecosystems. These services and benefits include what some consider to be long-term life support benefits to society as a whole. Examples of ecosystem services include watershed services, soil stabilization and erosion control, improved air quality, climate regulation and carbon sequestration, and biological diversity.

Indicators: Analysis relative to this issue compares the amount and proportion of land protected in non-development Land Use Designations (LUDs); the amount of inventoried roadless areas that would be protected under each alternative; and the amount of productive old-growth forest that would be protected under each alternative. Also, the values of the lands protected are considered. Non-use or passive-use values are discussed qualitatively and with examples provided from other studies.

Key Issue 2 – The Tongass National Forest needs to seek to provide a sufficient timber supply to meet the market demand and help maintain a vibrant economy in Southeast Alaska.

TTRA (Section 101) requires the Forest Service to seek to provide a supply of timber from the Tongass National Forest that meets the annual market demand and the market demand for each planning cycle, consistent with providing for the multiple-use and sustained yield of all renewable resources. With the cancellation of long-term timber contracts and the closure of two Southeast Alaska pulp mills in the 1990s (discussed in detail in Chapter 3 Environment and Effects), current demand for Alaska's National Forest timber depends on markets for sawn wood and the option of exporting manufacturing residues and lower grade logs. Future or planning cycle demand scenarios cover a wide range of issues and depend on rates of economic growth in key markets, conditions faced by competitors, and the rate of investment and innovation in Alaskan manufacturing.

Over the past half a century, the timber industry has been a major component of the economy of Southeast Alaska. However, with the closure of two Southeast Alaska pulp mills and the growth of tourism, timber has played a lesser role. Because the economy of Southeast Alaska is based on relatively few industries, maintaining an active timber industry is important for maintaining a well-diversified economy.

Indicators: Analysis relative to this issue compares the likely demand for timber based on capacity of the local industry and the amount of harvest made available to meet that demand. It also considers the type of wood (sawlogs and utility wood) made available and the usefulness of that wood type to the local industry, as well as the amount of timber that would be available from state and private sources. Finally, it considers the effects on the regional and national economies and the effects on the local communities.

Key Issue 3 – Protection of the wildlife habitat and biodiversity of the Tongass National Forest is of local and national significance and is affected by road development and timber harvest activities.

The Tongass National Forest supports a unique and important assemblage of wildlife including the largest population of brown bears and breeding bald eagles in the world, species of high importance for subsistence (e.g., Sitka black-tailed deer), an extensive array of endemic mammals and other species, and a large number of species that are at least partially dependent on old-growth habitats (e.g., marten and goshawk). Populations of many of these species and the biodiversity of Southeast Alaska are affected by timber harvest and the development of roads.

Although less than 10 percent of the productive old-growth habitat on the Tongass has been converted to young growth, the percentage is much higher for certain types of old growth, such as lowland and large-tree old growth. In addition, a high percentage of non-NFS lands have been harvested at a much higher rate. Therefore, the cumulative effects of harvest and road building on wildlife in Southeast Alaska are greater than the effects for the Tongass by itself.

Indicators: Analysis relative to this issue compares the amount of productive old-growth forest that would be protected under each alternative, as well as the percentages of biogeographic provinces that would be protected in reserves. It also considers the role of the managed lands (development LUDs) in providing wildlife habitat. It rates the alternatives in terms of the expert panel ratings conducted for the 1997 Forest Plan Revision EIS. Habitat changes, as documented by habitat amounts, changes in road densities, and habitat models are also used as indicators. Finally, cumulative harvest and road development on non-NFS lands is quantified and evaluated in conjunction with harvest and road development on NFS lands.

Changes between the Draft EIS and Final EIS

A number of updates and changes were made in the Final EIS in response to new information and to comments received on the Draft EIS. The main areas of change are described below:

1. Refinements were made to base Geographic Information System (GIS) coverages such as ownership, past harvest, roads, and LUDs to reflect updates due to changes in the existing condition and refinement of inventory data.
2. Because of refinements made to the base GIS coverages, the acreages and mileages associated with the existing condition and the alternatives changed, in many cases, and were updated throughout the document. Sometimes analysis methods were also refined, which resulted in changes to the quantification of effects.

3. Expanded discussion and analysis and incorporation of additional scientific references and studies were included in many sections of the Final EIS. This expanded discussion and analysis included elaboration on the risk and scientific uncertainty associated with issues.
4. The *Biodiversity* section of Chapter 3 was expanded to more fully address issues related to disproportionate past harvest, harvest on non-NFS lands and related cumulative effects, and effects on intact watersheds.
5. Alternative 1 was modified in response to comments on the Draft EIS. It now has a significantly smaller timber management land base, and excludes all inventoried roadless areas and many higher value roaded areas from commercial timber management. Examples include areas such as all of Kuiu, Baranof, and Kruzof Islands, much of Chichagof Islands, and all mainland areas.
6. Alternative 7 was modified in response to comments on the Draft EIS. It now deletes the requirement for buffers on Class III streams.
7. Further refinements and changes to the proposed Forest Plan were developed between the Draft EIS and Final EIS.
8. Appendix B was substantially updated and additional information on modeling and analysis techniques was added.
9. Appendix C was substantially revised based on updated and new information on the likelihood of various land adjustments.
10. A new Appendix D was developed, which presents background, rationale, assumptions, and additional analyses related to the old-growth conservation strategy, Wildlife Standards and Guidelines, and wildlife viability analyses as they relate to the Final EIS alternatives.
11. Although extensive mapping, quantification, and analysis of past harvest on non-NFS lands was completed for the Draft EIS, a more extensive analysis of past old-growth harvest, including the past disproportionate harvest of several categories of old growth, and the effects of this harvest, was completed and documented in the Final EIS, primarily in the *Biodiversity* section of Chapter 3;,a catalogue of past harvest is presented in Appendix E.
12. The Biological Assessment for threatened and endangered species that was originally developed for the 1997 Forest Plan Revision was updated and refined and included as Appendix F.
13. Appendix G was developed to summarize new information on timber demand and supply on the Tongass National Forest.
14. A new Appendix H was developed, which summarizes the comments received on the Draft EIS and the Forest Service responses to these comments. Copies of the letters received from agencies and elected officials, including tribal governments, are also included..

Organization of the Document

This Final EIS is organized into several chapters and a number of appendices. Chapter 1, "Purpose and Need," describes the reasons for proposing and completing a plan amendment. Chapter 2, "Alternatives," describes the process used to develop alternatives, explains the components of a Forest Plan, discusses alternatives not considered in detail, and describes the No-Action Alternative and Proposed Action Alternative as well as five other alternatives. Maps of the proposed LUDs under each alternative are also displayed in Chapter 2. Finally, a comparison of these alternatives based on the issues and significant environmental effects is presented.

The discussions of the “Affected Environment” and the “Environmental Consequences” are combined in Chapter 3, “Environment and Effects.” This is done so the environmental consequences (effects) of the alternatives on forest resources, and the background information needed to understand these consequences, are discussed together for each resource. The focus is on significant effects, with the analysis centered on the public issues. Chapter 3 also begins with a general description of the Tongass National Forest.

The Final EIS also includes a list of preparers; a list of agencies, organizations, and persons receiving copies of the document; a bibliography; a glossary; and an index (Chapters 4 through 8). Appendices to the Final EIS are contained in a separate volume (Final EIS Volume II). They provide more background on planning actions, certain resources and analyses, modeling and analysis techniques, a catalogue of past harvest, and a summary of the comments on the Draft EIS with Forest Service responses (Appendix H).

In addition to the two Final EIS volumes, three separate documents are associated with the Final EIS. First, a separate Summary booklet is included within the CD case. Second, the Record of Decision (ROD), which discloses the decision and its rationale, is published along with the Final EIS. Third, the Forest Plan, which includes goals and objectives, the management prescriptions for each LUD, Forest-wide standards and guidelines, plan implementation direction, a monitoring and evaluation plan, and related appendices, accompanies the ROD. In addition, a map packet includes color maps of the LUDs for each alternative and a ROD map that displays the LUDs associated with the decision.

The CD version of the Final EIS, Forest Plan, and ROD includes all of the documents described above, plus additional maps. As noted above, a Summary booklet is included in the CD case. Additional information, maps, and reference documents used in the Tongass Forest Plan Amendment process are contained in the planning record. Many of these documents and records are also available on the Forest Plan Adjustment Web site (http://tongass-fpadjust.net/). These can also be accessed through the main Tongass Web site (www.fs.fed.us/r10/tongass). The planning record in its entirety is incorporated here by reference.

CHAPTER 2
ALTERNATIVES

Alternatives

Introduction

Chapter 2 is divided into four parts:

1. A discussion of how alternatives were developed and of what constitutes an alternative;
2. A discussion of alternatives considered but eliminated from detailed study;
3. A full description of the alternatives that are considered in detail; and
4. A comparison of the alternatives considered in detail.

A color map for each of the seven alternatives considered in detail is included in the *Map Section* of the CD version of the EIS and in the *Map Packet* accompanying the hard copy version. These maps are also available on the EIS Web site at www.tongass-fpadjust.net. Each alternative map shows the locations of the Land Use Designations (LUDs) for that alternative.

Alternative Development Process

What a Forest Plan Includes

Land management planning may be compared to city, county, or borough zoning. Just as areas in a community are zoned as commercial (allowing business uses), industrial (allowing factories), or residential (allowing only homes, schools, etc.), the forest is also zoned to allow, or not allow, various uses and activities. Land management (forest plan) zoning is done through the use of LUDs. This Forest Plan only applies to federal lands within the Tongass National Forest.

Land Use Designations specify ways of managing an area of land and the resources it contains. LUDs may emphasize certain resources (such as remote recreation or old-growth wildlife habitat) or combinations of resources (such as providing for scenic quality in combination with timber harvesting). Each LUD has a detailed management prescription, which includes standards and guidelines.

Prescriptions are specific actions or treatments used in the management of forest resources, such as two-age timber harvest methods. Each management prescription specifies what is allowed to be considered for site-specific project proposals, and under what conditions. *Standards and guidelines* impose limitations on how, where, and when management activities are carried out, usually for specific resource protection purposes. Management prescriptions and standards and guidelines only apply to federal lands.

LUDs are assigned, or allocated, to specified areas of land. Under any one alternative, a given area of land will generally have only one LUD assigned to it; however, the Minerals and Transportation and Utility Systems LUDs are overlay LUDs and can apply to a given piece of ground when and if minerals or transportation/utility systems are to be developed on that piece of ground. In some other cases, two LUDs may apply to the same area, such as a Wild River within a Wilderness. In these cases, the more restrictive direction always applies. Some LUDs, such as Wilderness and LUD II, are congressionally designated and represent permanent allocations.

Forest resource use opportunities, such as timber harvesting or recreation, can be made available in different amounts. What lands to make available for timber harvest or how much of a particular kind of recreation opportunity to provide are questions that land management planning must also address. It is not always possible to provide all resource use opportunities in the amounts desired by everyone. The National Forest Management Act mandates the Forest Service to provide for multiple use and the sustained yield of the products and services obtained from the Forest.

The alternatives themselves are usually designed around a "framework" that establishes how much emphasis is placed on each of the key issues or other issues. The EIS alternatives are directly related to the issues described in Chapter 1. How alternatives were developed to address the issues is discussed below. The *Comparison of Alternatives* section at the end of this chapter also discusses ways in which the alternatives address the issues.

How Alternatives are Described

Each alternative for this EIS is presented in the same format. This includes the following components:

- **Framework.** The basis for alternative design.
- **Desired Condition.** A general description of the ecological, physical, and economic/social conditions that are expected in the future under each alternative framework.
- **Land Use Designations.** The acreages allocated to each Land Use Designation.
- **Standards and Guidelines and Management Prescriptions.** What changes to the existing Forest-wide standards and guidelines and management prescriptions are proposed?
- **Selected Outputs and Measure.** A summary of predicted outputs and measures associated with each alternative.

Land Use Designations

The alternatives are constructed using the LUD allocations defined in the 1997 Tongass Forest Plan as the base. This base represents the current Tongass Forest Plan and consists of Alternative 11 in the 1997 Tongass Forest Plan Revision Final EIS, adjusted by the 1997 Record of Decision (ROD) and subsequent non-significant Forest Plan Amendments made for projects since 1997.

The LUD allocations of the current Tongass Forest Plan define the No-Action Alternative (Alternative 5). The LUD allocations for the Proposed Action alternative (Alternative 6) are very similar to the No Action, but incorporate some adjustments. The other five alternatives differ more substantially from the No Action and Proposed Action in terms of their LUD allocations.

The management prescriptions for each specific LUD under the No Action alternative are the same as under the current Forest Plan (see Chapter 3 of the current Forest Plan, USDA Forest Service 1997b). These management prescriptions are summarized below, following a discussion of current Forest Plan LUDs. The management prescriptions for the other alternatives incorporate very slight modifications; these modifications are fully described in the amended Forest Plan that accompanies this Final EIS, and are summarized in the alternative descriptions, along with the exceptions to the amended Forest Plan.

Wilderness and National Monument

- **Wilderness and Wilderness National Monument** – Manage for the protection and perpetuation of essentially natural biophysical and ecological conditions and provide outstanding opportunities for solitude, primitive recreation, and scientific and educational uses, consistent with ANILCA, the Wilderness Act, and TTRA. Roads are normally not permitted and use of mechanical transport and motorized equipment is limited.

- **Non-wilderness National Monument** – Manage the non-wilderness portions of Admiralty Island and Misty Fiords National Monuments to facilitate development of significant mineral resources and to ensure that mining activities are compatible, to the maximum extent feasible, with the purposes for which the Monuments were established.

Mostly Natural Setting

- **LUD II** – Manage these Congressionally designated areas in a roadless state to retain the wildland character. Wildlife and fish habitat improvement and primitive recreational facility development may be permitted. Timber harvesting is limited to insect and disease control. Roads will not be built except to serve mining and other authorized activities and vital Forest transportation and utility system linkages. (These areas are sometimes referred to as "legislated LUD II.")

- **Research Natural Area** – Manage forest resources for research and education and/or to maintain natural diversity. Current natural conditions are maintained where possible. No timber harvest is allowed.

- **Enacted Municipal Watershed** – Manage enacted municipal watersheds to meet State Water Quality Standards for domestic use. Timber harvest is limited to insect and disease control; however, timber may be removed under conditions that safeguard the quantity and quality of water. Roads are generally limited to those needed to administer the municipal watersheds.

- **Old-growth Habitat** – Maintain a diversity of old-growth conifer habitats in their natural condition to favor old-growth associated fish and wildlife species. No timber harvesting will be scheduled and roads will be located outside the area when possible.

- **Semi-remote Recreation** – Provide motorized and non-motorized recreation opportunities in natural and natural-appearing environments where interaction with others is low and the opportunity for independence and self-reliance is moderate to high. Allow occasional concentrated recreation and tourism facilities in a natural-appearing setting. When present, roads are few and used primarily to expand and improve access to recreation opportunities or to permit access to other parts of the Forest and other ownerships. Timber harvest is limited to salvage of catastrophic events or beach log recovery.

- **Remote Recreation** – Provide recreation opportunities and experiences outside Wilderness in unmodified natural environments where interaction with other visitors is infrequent, and the opportunity for independence and self-reliance is high. Timber harvesting is limited to insect and disease control. Roads are generally absent.

- **Special Interest Area** – Provide for the inventory, maintenance, protection, and interpretation of areas with unique archeological, historical, recreational, scenic, geological, botanical, zoological, or paleontological features. No timber harvest is scheduled. Roads are normally not permitted unless compatible with interpretive objectives.

- **Wild River** – Maintain and enhance the outstandingly remarkable values of river segments that qualify the river to be classified a Wild River and recommended in the 1997 Tongass Forest Plan ROD. Shorelines are primitive and undeveloped. Timber harvesting is limited to insect and disease control. Roads are generally not present. Access is by trail, airplane, or boat.

- **Scenic River** – Maintain and enhance the outstandingly remarkable values of river segments which qualify the river to be classified a Scenic River and recommended in the 1997 Tongass Forest Plan ROD. Shorelines are largely undeveloped but may be accessible in places by roads. Timber harvesting is limited by the ability of the landscape to visually absorb the activity. Roads are designed to be compatible with the landscape.

- **Recreational River** – Maintain and enhance the outstandingly remarkable values of river segments that qualify the river to be classified a Recreational River and recommended in the 1997 Tongass Forest Plan ROD. Shoreline development may occur and the river may be readily accessible by road. Timber harvesting is allowed with priority to maintain existing and proposed recreation sites within the corridor. Roads are permitted.

Moderate Development

- **Experimental Forest** – Manage to provide a variety of long-term opportunities for Forest research and demonstration areas. Timber harvesting will occur only for these purposes. Roads may be developed to facilitate ongoing research.

- **Scenic Viewshed** – Management activities are not visually apparent to the casual observer in the near distance from visual priority travel routes and use areas. In the middle to background distance, activities are subordinate to the landscape character of the area. Timber harvest is allowed and roads are permitted.

- **Modified Landscape** – Manage for a variety of uses. Management activities are subordinate to scenic quality as seen in the near distance. In the middle to background distance, activities may dominate but are designed to be compatible with features found in the characteristic landscape. Timber harvest is allowed and roads are permitted.

Intensive Development

- **Timber Production** – Manage the area to maintain and promote industrial wood production. These lands will be managed to advance conditions favorable for the timber resource and for long-term timber production. Roads are permitted.

Overlay LUDs

- **Minerals** – Encourage the exploration and development of mineral resources in areas having high potential for mineral commodities, including nationally designated strategic and critical minerals. Until mineral activities are initiated, the area will be managed according to the underlying LUD.

- **Transportation and Utility Systems** – Emphasize existing and potential state-identified major public transportation and utility systems. Until transportation or utility systems are constructed, the area will be managed according to the underlying LUD.

Development of Potential Alternatives

As indicated by the Ninth Circuit Court of Appeals, there is a need to evaluate a wide range of alternatives that relate to varying degrees of development of roadless lands, while at the same time providing a supply of timber that corresponds with the full range of timber demand scenarios. Therefore, the array of EIS alternatives was designed to address a full range of roadless development and timber supply/demand levels. Adjustments to the standards and guidelines of the Forest Plan were also incorporated into various alternatives to address clarifications and updates identified as needed in the 5-Year Review and by Forest Service staff.

Basic tools used in the development of the alternatives were the recent timber demand projections (Brackley et al. 2006), the existing inventory of roadless lands, and various sources of information regarding the qualities of the roadless lands. In addition, because of the rigorous level of scientific review that went into designing the current conservation strategy, strong consideration was given to maintaining its elements. Other alternative proposals considered during the 1997 Forest Plan Revision and the 2003 Supplemental EIS processes were given consideration.

A total of 49 alternatives were considered as part of the alternative development process. Of these, 42 alternatives were eliminated from detailed study and are discussed in the following section (*Alternatives Eliminated from Detailed Study*). The remaining seven alternatives are considered in detail in this EIS.

The set of alternatives that are analyzed in detail were designed to fully bracket the range of timber demand scenarios identified by Brackley et al. (2006). Equally important, they were designed to range from very limited development of inventoried roadless areas to more intensive development within roadless areas. This range is captured by the seven alternatives.

Brackley et al. (2006) described four timber demand scenarios: limited lumber production, expanded lumber production, medium integrated industry, and high integrated industry. The following table compares the projected demand for 2022 under these four scenarios with the Allowable Sale Quantity (ASQ) identified for the second decade of each of the alternatives considered in detail (ASQ is discussed in more detail below in the *Alternatives Considered in Detail* section).

Table 2-1
Projected Demand for 2022 under Brackley et al.'s Four Timber Demand Scenarios

Brackley et al. Demand Scenarios & Projected 2022 Demand[1] (MMBF)	Alternatives Considered in Detail & Second-Decade ASQ (MMBF)
	Alternative 1 – 49
Scenario 1 – 68	
	Alternative 2 – 152
Scenario 2 – 187	
	Alternative 3 – 203
Scenario 3 – 204	
	Alternative 5 – 267
	Alternative 6 – 267
Scenario 4 – 342	Alternative 4 – 342
	Alternative 7 – 421

[1] These figures include total volume that would need to be harvested to meet the demand projected by Brackley et al. 2006

Alternatives 1 through 4 were designed to correspond with Scenarios 1 through 4, respectively, while also responding to other concerns. The discrepancies between the second decade ASQs for Alternatives 1 and 2 and projected demand for 2022 under Scenarios 1 and 2 reflect these concerns.

The ASQ for Alternative 1 is 19 MMBF (28 percent) below the projected demand of Scenario 1. There are several reasons for this difference. First, the purpose of Alternative 1 is to depict the current situation, meaning annual timber harvest levels over the last few years of around 50 MMBF. In addition, Alternative 1 responds to the court's direction and public comments by scheduling no timber harvest in roadless areas, as discussed below. This alternative also responds to recommendations from the public to avoid harvest on Kuiu Island. The ASQ of Alternative 2 is 25 MMBF (19 percent) below the projected demand of Scenario 2. The purpose of Alternative 2 is to display an alternative that restricts development activities to lower value roadless areas. Alternative 3 differs from Scenario 3 by only 1 MMBF; Alternative 4 matches Scenario 4 exactly.

Alternatives Eliminated from Detailed Study

The Forest Plan revision process started in 1987 and resulted in the development of dozens of alternatives that were described in the Draft EIS (1990), Supplement to the Draft EIS (1991), Revised Supplement (1996), Final EIS (1997), and Supplemental EIS (2003). In addition, a 1992 draft version of the Final EIS included alternatives that became the basis of some 1996 Revised Supplement and 1997 Final EIS alternatives. Each of these alternatives was considered for detailed study and comparison in this EIS, in their original form or in a modified form. Altogether, 41 alternatives were considered for detailed study prior to the selection of the EIS alternatives—39 of these were based on previous alternatives and 2 were new ones. The 39 previous alternatives are summarized in Table 2-2.

These alternatives were considered in light of the key issues and the purpose and need. They ranged in allowable sale quantity (which is the maximum annual average amount of timber that can be sold from the suitable forest land base) from 0 to almost 700 MMBF per year. Development LUD acres in these alternatives ranged from a few hundred acres to almost 8 million acres and forest lands suitable for timber harvest ranged from 0 to over 2 million acres.

Five alternatives, which were largely based on previously developed alternatives, and two new alternatives were selected for detailed study. Therefore, 34 of the previously developed alternatives were considered, but eliminated from detailed study. The reasons for not selecting them were either that they were similar to and within the range of the selected alternatives, they were outside the range of timber demand estimates, or they would result in substantial changes to the current Forest Plan standards and guidelines that are not warranted based on the purpose and need or the key issues.

In addition to the 41 alternatives discussed above, 8 other alternatives were considered, but not evaluated in detail. Therefore, overall, 49 alternatives were considered and evaluated to varying degrees, with 7 of these being analyzed in detail and 42 being eliminated from further detailed study. The eight additional alternatives that were not analyzed in detail include three alternatives with timber volumes below the volume to be harvested under Alternative 1, one alternative described by The Nature Conservancy and Audubon Alaska, modified versions of Alternatives 4 and 7, an alternative proposed by the Southeast Conference, and a partial alternative proposed by the City and Borough of Yakutat. These eight alternatives are described in the following paragraphs.

Table 2-2
Tongass Forest Plan Alternatives Considered in Detail: 1990 – 2003

Alternative and Source		ASQ (MMBF annual)	Suitable lands (Acres X 1,000)	Non-Development LUDs (Acres X 1,000)	Development LUDs (Acres X 1,000)
1	1997	0	0	16,700	200
1	1996	0	74	16,700	200
6	2003	92	344	15,700	1,200
8	2003	96	351	15,700	1,200
5	1997	122	786	12,100	4,800
4	1997	130	845	11,700	5,200
5	1996	139	1,400	12,100	4,800
4	1996	145	1,507	11,700	5,200
7	2003	174	521	14,300	2,600
A	1990	181	536	13,600	3,300
5	2003	209	589	13,800	3,100
3	2003	236	620	13,500	3,400
3	1997	256	795	12,700	4,200
1	2003	259	664	13,200	3,700
2	2003	259	664	13,200	3,700
4	2003	259	664	13,200	3,700
11	1997	267	676	13,200	3,700

Sources: 1990 Draft EIS, 1991 Supplement to the Draft EIS, 1996 Revised Supplement to the Draft EIS, 1997 Final EIS, and 2003 Supplemental EIS.

Zero to Very Low Volume (ASQ) Alternatives

Consideration was initially given to evaluating zero to very low volume alternatives and recommendations were also made in Draft EIS comments that various zero to very low volume alternatives should be considered for detailed evaluation. As a result, a no-commercial harvest alternative was considered, an alternative with an ASQ at a stable level significantly below Alternative 1 was considered, and a declining volume alternative that started with an ASQ near the Alternative 1 level, but declined over time, was considered. Partially in response to these comments, the development land base of Alternative 1 was significantly reduced and the ASQ was slightly reduced between the Draft EIS and the Final EIS. As a result, even Alternative 1 would produce only 28 MMBF of NIC I sawlogs (the type that could be utilized by the existing sawmills) on an annual basis. This volume is equivalent to less than 15 percent of the estimated mill capacity of the four largest existing sawmills, 11 percent of the estimated active installed processing capacity of all existing Southeast Alaska mills, and only 7 percent of the total processing capacity of existing Southeast Alaska mills. In addition, the recent actual mill output level has been about 35 MMBF. Even Alternative 1 is considered to be a non-sustainable alternative for the existing timber industry because it does not meet these volume levels (see *Economic and Social Environment*, Regional and National Economy, in Chapter 3). Because the three additional alternatives under consideration, by definition, would produce a significantly lower volume than Alternative 1, they would clearly not be sustainable for even a portion of the existing timber industry.

The Tongass Timber Reform Act requires the Forest Service “to seek to meet the market demand.” Providing a timber volume that would meet neither the current estimated annual demand nor the recent actual mill output levels, and which would produce only a fraction of estimated existing mill capacities, would clearly not be consistent with TTRA and, therefore, is determined to not be a reasonable alternative. Alternative 1 provides an alternative “sideboard” at the low end of the timber volume range that is already in the “non-sustainable” category.

The Nature Conservancy/Audubon Alaska Alternative

A number of organizations suggested that they might generate a low-harvest alternative for consideration. The only low-harvest alternative that was described was one by The Nature Conservancy and Audubon Alaska in their Conservation Assessment for Southeast Alaska (Albert and Schoen 2007).

This alternative was defined based on modeling of relative ecological values and the ranking of relative suitability for timber production. It includes conservation priority watersheds, other watersheds to be managed for intact conditions, as well as timber production and integrated management watersheds. The EIS team determined that Alternatives 1, 2, and 3 captured the range defined by this alternative and they also represented alternatives that were similar to others that would be developed by other groups (e.g., they avoid the roadless areas and intact watersheds or different combinations of high-value roadless areas or intact watersheds).

Modified Alternatives 4 and 7

A modified version of Alternatives 4 and 7 were evaluated for consideration. The modification involved replacing portions of the development LUDs in these alternatives with the Old-Growth Habitat LUDs from Alternative 6. It was determined that the modified Alternative 4 did not produce significantly more timber volume than Alternatives 5 and 6 and the modified Alternative 7 was not substantially different than Alternative 4. Therefore, these modified alternatives were well within the range of the existing alternatives and it was decided they did not need to be analyzed in detail.

Southeast Conference Alternative

In its comments on the Draft EIS, the Southeast Conference (an association of municipalities, businesses, Native corporations and village councils, civic organizations, and individuals from Southeast Alaska) identified specific lands they believe should be allocated to the Timber Management LUD to allow for reestablishment of an integrated timber industry in Southeast Alaska. These lands were reviewed by the EIS team and it was determined that the vast majority of these lands (plus additional lands) were included as development LUDs in Alternative 7 and most of them were also included in several other alternatives. The lands that were not included were identified as Old-Growth Habitat, Special Interest Area, or Experimental Forest LUDs in most of the alternatives. It was determined that the current range of alternatives captured these lands and there was no need to develop a new alternative based on them.

City and Borough of Yakutat Alternative

In its comments on the Draft EIS, the City and Borough of Yakutat recommended a modification of Alternative 2 for the Yakutat Ranger District. This alternative involved reducing the development LUDs in the ranger district and changing them to Semi-Remote Recreation. Between the Draft EIS and the Final EIS the development LUDs of Alternative 1 in this ranger district were converted to Semi-Remote Recreation. Therefore, it was determined that the City and Borough of Yakutat recommendation was bracketed by the revised Alternative 1 and Alternative 2 in the Final EIS and, therefore, it was not necessary to add an additional alternative for this specific area.

Alternatives Considered in Detail

The following section defines terminology and presents information regarding several aspects of the alternatives. The alternatives considered in detail are presented afterward.

The Allowable Sale Quantity

The amount of timber that could be sold under a Forest Plan is expressed as an Allowable Sale Quantity (ASQ). The ASQ is the maximum amount of timber that may be sold from the area of suitable land contained under the Forest Plan within a given decade (although it is usually expressed in average annual terms). It is neither a targeted amount, nor is it a required amount. It is a ceiling. The amount of timber offered for sale in any year can exceed the annual average as long as the total decade's ASQ is not exceeded, and can also be anywhere below the annual average; the amount offered for sale over a decade can be below the decadal ASQ. Many factors can result in timber sale offerings that are below the average annual ASQ, including lack of program funding, new resource issues that need to be addressed, changes in timber markets, sales delayed by appeals or lawsuits, or other factors that reduce the actual volume.

In some situations, timber can be harvested from unsuitable lands and can contribute to satisfying timber demand, but cannot contribute to the ASQ. An example is the timber produced from thinning of second-growth stands for wildlife habitat enhancement, within LUDs identified as not suitable for timber production.

Non-interchangeable Components

Economics is an important consideration in determining what land can be harvested; however, economic conditions can fluctuate greatly from year to year, shifting specific forest stands from being economic to uneconomic to harvest. As a result, the Tongass National Forest uses the concept of non-interchangeable components

(NIC) to consider economics. NICs allow the separation of ASQ into discrete, individually accountable categories. All seven alternatives have an ASQ for the first decade made up of two NICs:

> **NIC I.** Normal operable volume scheduled from suitable lands that are available for harvest using standard logging systems. This is the most economically operable ground and is typically where the Tongass National Forest has been offering most sales.
>
> **NIC II.** Non-standard (difficult and isolated) operable volume scheduled from suitable lands that are available for harvest using logging systems not in common use. These lands are currently considered economically and technologically marginal. In the past, this land has rarely been economical to harvest.

Chargeable timber volume from one NIC cannot be substituted for the achievement of the volume limit of another NIC, nor can the limits on the sale of chargeable timber volume associated with each NIC be exceeded.

Standards and Guidelines and Management Prescriptions

The Forest-wide standards and guidelines in Chapter 4, the management prescriptions in Chapter 3, and other chapters of the current Tongass Forest Plan (USDA Forest Service, 1997b) apply to Alternative 5, the No-Action Alternative in this EIS, and are not repeated here. An updated and edited version of the 1997 Forest Plan (as amended) was developed for Alternative 6, the Proposed Action, and for Alternatives 1, 2, and 3. A Proposed Forest Plan was released in January 2007 with the Draft EIS at the beginning of the comment period. This Proposed Forest Plan is modified and updated further for this Final EIS, and is referred to as the Final Proposed Forest Plan (see below). Alternatives 4 and 7 also follow the updated Forest Plan , with the exceptions noted in their alternative descriptions (see below).

Applicable LUD management prescriptions and Forest-wide standards and guidelines are discussed throughout the environmental consequences sections of Chapter 3 because they serve as the basic mitigation measures for individual projects under the Forest Plan. The Forest-wide standards and guidelines, and the LUD-specific standards and guidelines that constitute the management prescriptions, are the full set of mitigation measures for each alternative.

Goals Common to All Alternatives

Air. Maintain the current air resource condition to protect the Forest's ecosystems from on- and off-Forest air emission sources.

Biodiversity. Maintain healthy forest ecosystems; a mix of habitats at different spatial scales (site, watershed, island, province, and forest) capable of supporting the full range of naturally occurring flora, fauna, and ecological processes native to Southeast Alaska.

Ecosystem Services and Non-Use Values. Maintain the broad range and high level of ecosystem services (e.g., watershed, water quality, air quality, biodiversity), and non-use values (e.g., existence, option, and bequest values associated with natural areas) that are provided by the Tongass National Forest.

Fish. Maintain or restore the natural range and frequency of aquatic habitat conditions on the Tongass National Forest to sustain the diversity and production of fish and other freshwater organisms.

Heritage Resources. Identify, evaluate, preserve, and protect heritage resources.

Local and Regional Economies. Provide a diversity of opportunities for resource uses that contribute to the local and regional economies of Southeast Alaska.

Rare Natural Areas. Protect a variety of areas with natural, scenic, or geologic features distinct to the region, including areas set aside specifically for future research needs.

Research. Continue to seek out and promote research opportunities that are consistent with identified information needs.

Soil and Water. Maintain soil productivity Forest-wide, and minimize soil erosion resulting from land-disturbing activities. Minimize sediment transported to streams from land-disturbing activities. Maintain and restore the biological, physical, and chemical integrity of Tongass National Forest waters.

Subsistence. Provide for the continuation of subsistence uses and resources by all rural Alaskan residents.

Wetlands. Minimize the destruction, loss or degradation of wetlands, and preserve and enhance the associated wetland functions and values.

Wilderness. Manage designated Wilderness to maintain an enduring wilderness resource while providing for public access and uses consistent with the Wilderness Act of 1964 and the Alaska National Interest Lands Conservation Act of 1980 (ANILCA).

Descriptions of the Alternatives

Each alternative description includes the following components: 1) a framework; 2) a general description of the desired condition; 3) a table with the acreages allocated to each LUD; 4) a map (included in the *Map Packet* accompanying the EIS hard copy or in the *Map Section* of the CD version) showing the composition of LUDs across the Forest; 5) a map showing the distribution of development, natural setting, and wilderness LUDs; 6) a description of proposed changes to the current Forest-wide standards and guidelines and management prescriptions; and 7) a quantification of outputs and measures associated with each alternative.

The management prescriptions (i.e., LUD-specific standards and guidelines) for each LUD are included in the 1997 Forest Plan, as amended, or in the Final Proposed Forest Plan (see next section), as are the Forest-wide standards and guidelines that apply to each alternative. Details on the modeling of each alternative are included in Appendix B to this EIS (included Volume II).

In the LUD tables for each alternative, the changes from existing acreages represent the differences between the decisions made in the 1997 Tongass Forest Plan Revision ROD, as amended, and the Forest Plan Amendment EIS alternatives.

The goals common to all alternatives are provided below. In addition, the Tongass Timber Reform Act (Section 101) direction for the Tongass to "seek to provide a supply of timber which 1) meets the annual market demand for timber from such forest and 2) meets the market demand from such forest for each planning cycle" will be followed by each alternative "to the extent consistent with providing for the multiple use and sustained yield of all renewable forest resources," as determined by that alternative, and subject to appropriations and applicable law.

Summary of Final Proposed Forest Plan

The 1997 Forest Plan (USDA Forest Service 1997b), as amended, is the plan associated with Alternative 5, the No-Action Alternative. A number of changes to the Forest Plan text are being proposed under the other alternatives, based on the

Forest Plan 5 Year Review and Forest Service staff recommendations. Most changes were incorporated into a Proposed Forest Plan (Land and Resource Management Plan), which accompanied the Draft EIS. These changes were modified and updated for the Final EIS and the major changes being proposed are summarized in this section. The individual alternative descriptions on the following pages only identify items that are not consistent with the Final Proposed Forest Plan, which is defined by the Proposed Forest Plan that accompanied the Draft EIS, as modified in this section. A summary of the main changes that are incorporated into the Final Proposed Forest Plan are provided below.

Management Prescriptions

- Edits and clarifications were made regarding karst management programs, sacred site protection, minerals and geology, off-highway vehicle use, scenery management, and other areas for most LUD prescriptions
- Substantial edits and clarifications were made to the Wilderness and Wilderness National Monument LUD prescriptions

Forest-wide Standards and Guidelines

- Clarifications were made to the standards and guidelines regarding steep slopes and soil stability in the *Soils* and *Water* section.
- Clarifications were made to the standards and guidelines on Class III and IV streams and edits were made to the other standards and guidelines in the Fish section
- The detailed stream process group-specific riparian standards and guidelines are presented in an appendix in the Final Proposed Forest Plan, instead of in the main body of the standards and guidelines, which is the way they were presented in the Proposed Forest Plan that accompanied the Draft EIS.
- A new section was added to Chapter 4 on Invasive Species.
- A new section was added to Chapter 4 on Plants.
- The Threatened, Endangered, and Sensitive Species standards and guidelines are incorporated into subsections under Fish, Wildlife, and Plants (as appropriate) in the Final Proposed Plan, instead of in a separate section as in the Proposed Plan that accompanied the Draft EIS.
- The goshawk foraging habitat and the marten habitat standards and guidelines in the *Wildlife* section were deleted and replaced with a Forest-wide legacy standard and guideline in the Proposed Forest Plan that accompanied the Draft EIS. In addition, the legacy standard and guideline for the Final Proposed Forest Plan is revised further. The revised standard and guideline requires legacy forest structure to be left only in harvest units greater than 20 acres and only in higher risk VCUs, as previously defined (49 VCUs).
- The goshawk nesting habitat standard and guideline in the *Wildlife* section was revised in the Proposed Forest Plan that accompanied the Draft EIS. In addition, the goshawk nesting habitat standard and guideline for the Final Proposed Forest Plan is revised further. The revised standard and guideline permits nesting habitat protection measures to be removed if, after 2 consecutive years of monitoring, evidence of confirmed or probable nesting is no longer observed.
- The requirement to conduct inventories to determine the presence of nesting goshawks for proposed projects that affect goshawk habitat is included in the

Final Proposed Forest Plan (this was inadvertently removed from the Proposed Forest Plan that accompanied the Draft EIS).

- New standards and guidelines on sacred site protection were added in the *Heritage Resources and Sacred Sites* section.
- Extensive edits were made to the Karst and Cave Resources standards and guidelines and the Karst and Cave Resources appendix.
- Substantial edits were made to the Minerals and Geology standards and guidelines.
- Substantial edits were made to the Recreation and Tourism standards and guidelines. The detailed Recreation Opportunity Spectrum-specific standards and guidelines are presented in an appendix in the Final Proposed Forest Plan, instead of in the main body of the standards and guidelines, which is the way they were presented in the Proposed Forest Plan that accompanied the Draft EIS.
- The Scenery standards and guidelines were converted from the Visual Management System to the Scenery Management System.
- Edits were made to off-highway vehicle standards and guidelines in the *Lands* section.
- Edits were made to the road storage and decommissioning standards and guidelines in the *Transportation and Utilities* section.

In addition, there are a number of changes to other Forest Plan sections. These include changes to the Goals and Objectives (Chapter 2 of the Plan) and Monitoring and Evaluation (Chapter 6 of the Plan) chapters and to a number of the Forest Plan appendixes, including Appendix B (Information Needs), Appendix F (Visual Priority Routes and Use Areas), Appendix I (Karst and Caves), Appendix K (Old-Growth Habitat Reserve Criteria), and Appendix L (Resource Schedules).

Finally, the 1982 Planning Regulations implementing NFMA include identification of Wildlife Management Indicator Species (MIS) in Forest Plans. The primary intent of MIS was to monitor populations of selected species to see if longer term trends were indicating they could become threatened or endangered across the national forest. The 1997 Forest Plan identified 13 wildlife and 4 fish MIS species with associated monitoring guidelines. The Tongass National Forest has analyzed MIS monitoring information assembled since 1997. Chapter 3 includes information for each of the species. It has been determined this information is lacking in sufficient detail to help guide management of the selected species on the Forest. The Tongass hosted an interagency review of the Forest Plan Conservation Strategy in April of 2006, which included updated information related to most of the MIS species. Much discussion at the review and in other related venues locally and nationally indicate monitoring should be more focused on wildlife habitats instead of species population trends by themselves. Interagency discussions related to wildlife monitoring and the MIS themselves are ongoing. As a result, the Monitoring and Evaluation chapter in the Final Proposed Plan is revised to be more focused, relative to the version in the Proposed Forest Plan that accompanied the Draft EIS. It is anticipated that the current list of MIS may be revised in the future, but a change in MIS is not part of the Final Proposed Plan.

Proposed LUD Changes Common to Most Alternatives

The LUD allocations for each alternative are described in the following alternative-specific descriptions. The alternatives do not vary in terms of the acreage allocated to congressionally designated areas (i.e., Wilderness, National Monument, and LUD II), nor do they vary in terms of allocations to Research Natural Areas, Enacted Municipal Watersheds, or Wild, Scenic, or Recreational River LUDs. However, they do vary with respect to the other non-development LUDs and all of the development LUDs. The LUDs for each alternative are displayed on alternative LUD maps that accompany this EIS.

Proposed changes to the Special Interest Area and Experimental Forest LUDs are common under all alternatives except Alternative 5, which would follow the 1997 Forest Plan (as amended) for these two LUDs. The proposed changes to Special Interest Area and Experimental Forest LUDs are quantified in the following alternative description sections and shown on the alternative LUD maps, and are described in detail in the *Other Special Land Use Designation* section of Chapter 3.

Proposed changes to the Old-Growth Habitat LUD are common under Alternatives 1, 2, 3, and 6, and are as a result of an interagency process that took place in parallel with this EIS, and was initiated in 2006 and completed in 2007. Under this process, the Tongass worked with the Alaska Department of Fish and Game and the U.S. Fish and Wildlife Service to conduct a comprehensive review and mapping effort for all small old-growth reserves (OGR). The objective of the interagency team review was to develop a consensus biological recommendation on small OGR composition and locations that was consistent with the Forest Plan. This process included the development of a biological recommendation, the refinement of that proposal with Forest Service Ranger District staff, and further refinement by the Forest Supervisor. The refinement process was conducted in order to consider multiple-use objectives in addition to pure biological ones. The final proposal is included in Alternatives 1, 2, 3, and 6 of the Final EIS. Alternative 5 retains the 1997 Plan (as amended) reserve network and the reserves proposed under Alternatives 4 and 7 are not affected by this proposal. Further information on the refinement of small OGRs is included in Appendix D.

Alternative 1

Framework

Under this alternative, forest management would provide a mix of National Forest uses and activities, but would emphasize maintaining inventoried roadless areas, associated fish and wildlife values, and unroaded recreation, tourism, and subsistence opportunities, relative to the current Forest Plan. Timber would be managed within the roaded land base and all inventoried roadless areas would remain in a natural condition. In addition, a number of higher value roaded areas, including all of Kuiu, Baranof, and Kruzof Islands, many portions of Chichagof Island, all mainland areas, and other areas, would be excluded from commercial timber management. A total of 840,000 acres of the Tongass would be in development LUDs and 15.9 million acres would be in non-development LUDs. The majority of the lands changed to non-development LUDs from development LUDs (in the current Plan) would be designated Semi-Remote Recreation. Specific LUD changes under this alternative would include the addition and modification of a number of Geologic Special Interest Areas, recommendations to change the Young Bay Experimental Forest to Semi-Remote Recreation and the Cowee-Davies Creek watersheds from Scenic Viewshed to Experimental Forest, and converting a large area of Remote Recreation LUD north of Juneau to Semi-Remote Recreation. It also would include extensive refinements to the boundaries of the small Old-Growth Reserves, based on a recently completed interagency evaluation.

This alternative would approximately correspond with Scenario 1 (limited lumber production) of the Brackley et al. (2006) timber demand study. It is similar to Alternative 8 of the 2003 SEIS in terms of the areas allocated to non-development LUDs.

Desired Conditions

The vast majority of the currently undisturbed areas of the Forest remain in a natural state and all existing inventoried roadless areas remain roadless. Old-growth conditions prevail on forest lands within these roadless areas. A small, but predictable and sustainable supply of forest products contributes to a very limited Southeast Alaska timber industry, probably based primarily in Ketchikan and Prince of Wales Island. A mixture of old growth, recently harvested areas, and various ages of young growth occurs within roaded areas. Recreation, tourism, and subsistence opportunities emphasize natural setting types, although roaded opportunities expand slightly from current conditions due to construction of additional roads primarily in already roaded areas.

Land Use Designations

If Alternative 1 is selected, the LUD allocation acres shown in Table 2-3 would result. Figure 2-1 shows the distribution of LUDs across the Tongass under Alternative 1 according to three LUD groups (see Table 2-3 for definitions of the LUD groups). A complete LUD map is provided as the Alternative 1 map in the *Map Section* of the CD version of this EIS or in the *Map Packet* accompanying the EIS hard copy.

Management Prescriptions and Standards and Guidelines

Under Alternative 1, the management prescriptions and standards and guidelines identified in the Final Proposed Land and Resource Management Plan would be adopted. These are generally the same as the management prescriptions and standards and guidelines in the 1997 Forest Plan, as amended; however, a number of changes and refinements are proposed. A summary of the main changes to the 1997 Forest Plan, as amended, is provided above in the section titled "Final Proposed Forest Plan."

Selected Outputs

Table 2-4 displays selected outputs and other measures associated with this alternative.

Table 2-3
Land Use Designations for Alternative 1[1]

Land Use Designation	Acres Allocated	Net Change from Current Forest Plan Acres[2]
Wilderness LUD Group		
Wilderness	2,637,292	0
National Monument[3]	3,278,734	0
Total for Wilderness LUD Group	**5,916,026**	**0**
Natural Setting LUD Group		
LUD II	721,002	0
Research Natural Area	26,093	0
Old Growth	1,221,174	38,749
Special Interest Area	221,174	46,712
Enacted Municipal Watershed	45,226	0
Wild, Scenic, and Recreational River	117,319	0
Remote Recreation	2,369,831	238,776
Semi-Remote Recreation	5,296,773	2,442,548
Total for Natural Setting LUD Group	**10,018,592**	**2,766,786**
Development LUD Group		
Experimental Forest	31,405	14,310
Scenic Viewshed	59,296	(417,923)
Modified Landscape	188,357	(413,005)
Timber Production	560,129	(1,950,169)
Total for Development LUD Group	**839,187**	**(2,766,786)**
Total National Forest System Lands	**16,773,804**	**0**

1 When more than one LUD is applied to the same area, such as a Special Interest Area within Wilderness, only the acreage of the more restrictive LUD is included, except that total Wilderness, Wilderness National Monument, and LUD II acres are always shown. The acreage for the Minerals LUD would be 249,570; these acres are not included in the table because the Minerals LUD is an overlay. No acreages have been calculated for the Transportation and Utility Systems LUD because it is a series of corridors with undefined width and imprecise locations. Totals may not exactly equal the sum of individual entries due to rounding.

2 These changes from current Forest Plan acres are the differences from the decision made in the 1997 Tongass Forest Plan Revision ROD, as amended, which is represented by Alternative 5.

3 The majority of the National Monument acres are wilderness; only 166,942 acres are non-wilderness.

4 Small old-growth reserves and Special Interest Area LUDs increased relative to Alternative 5; however, they overlap extensively, especially on Heceta, Kosciusko, and northeast Chichagof Islands, and the acreages where they overlap were counted with Special Interest Areas.

Figure 2-1
Wilderness, Natural Setting, and Development LUDs on the Tongass National Forest under Alternative 1

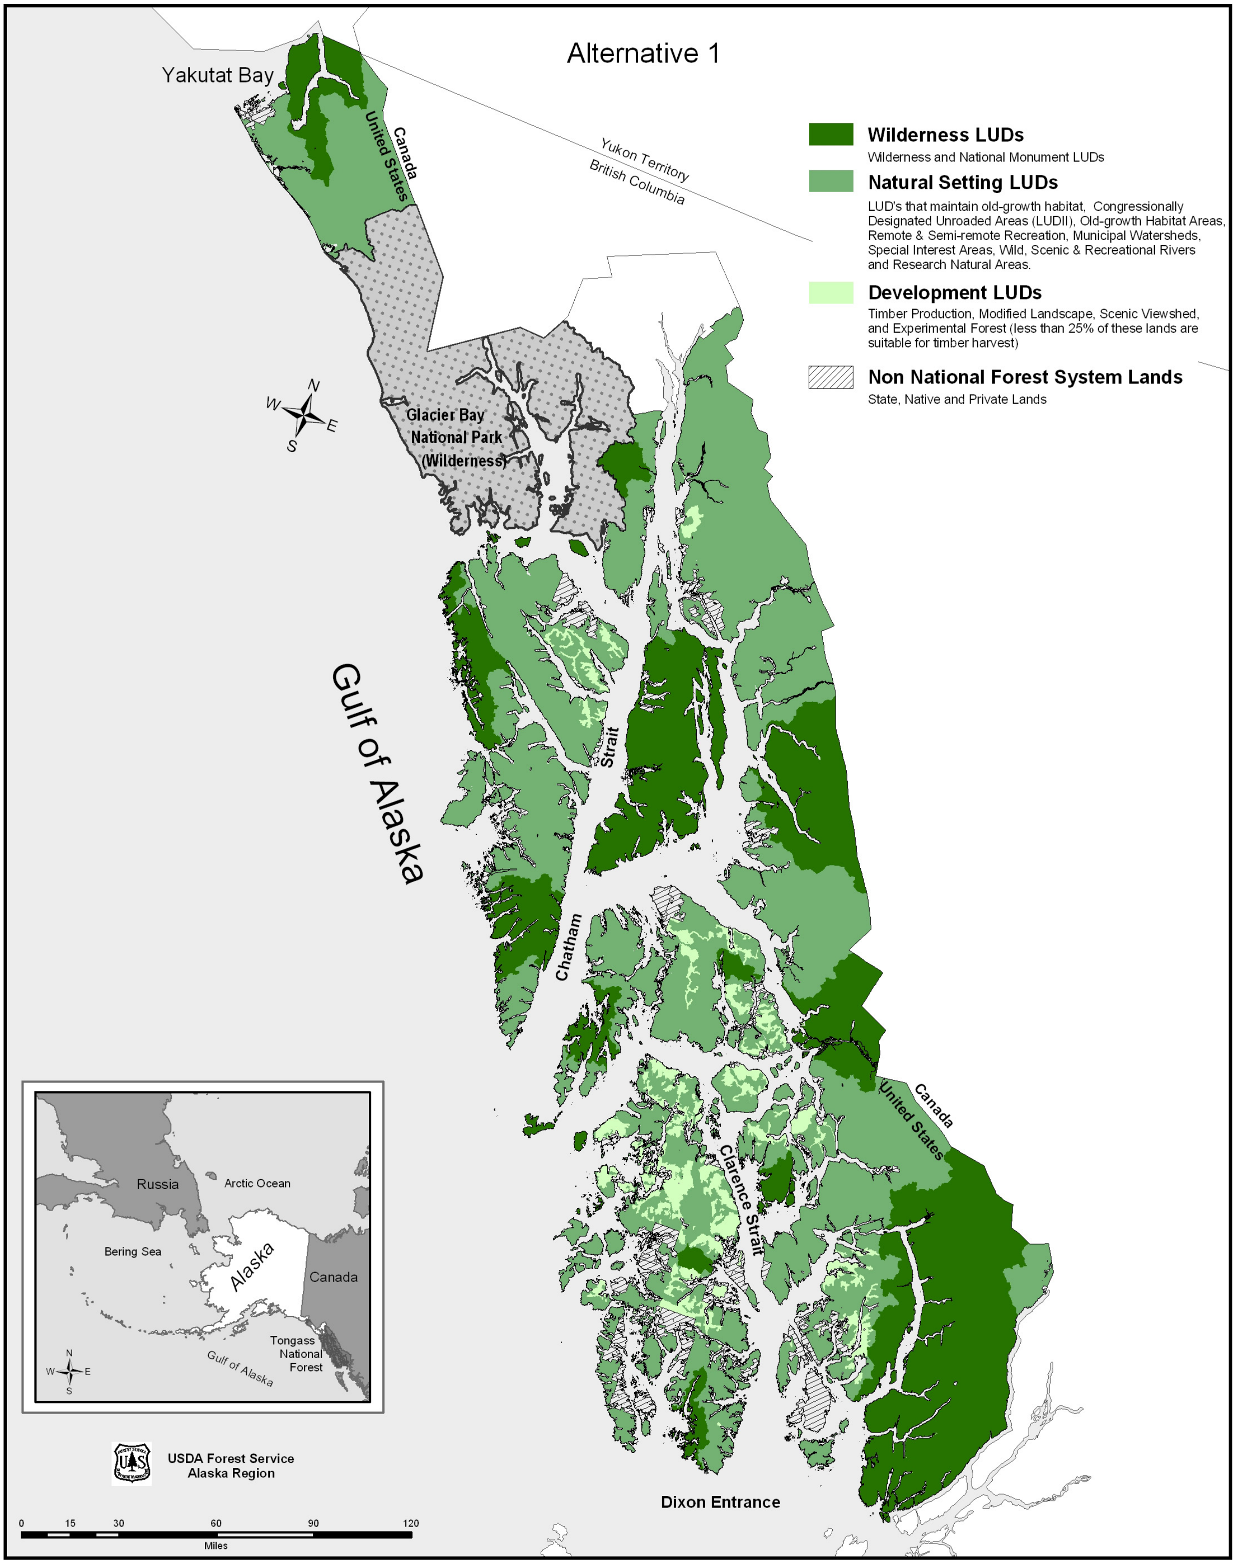

Table 2-4
Selected Outputs and Measures Associated with Alternative 1[1]

Resource/Category	Output/Measure
Percent in Wilderness LUD Group	35%
Percent in Natural Setting LUD Group	60%
Percent in Development LUD Group	5%
Amount of Development LUDs in Inventoried Roadless Areas (millions of acres)[2]	0.0
Percent of Current Productive Old Growth Protected in Reserves (Wilderness/Nat. Mon. and Natural Setting LUDs)	93%
Productive Old Growth after 100+ Years (millions of acres)	4.9
Estimated Forest Land Suitable for Timber Production (acres)[3]	312,000
Scheduled Suitable Forest Land (acres)[3]	144,000
Allowable Sale Quantity or ASQ (millions of board feet)[4]	
1st Decade ASQ	49
2nd Decade ASQ	49
Maximum New Road Construction after 100+ Years (miles)	774
Maximum Average Annual Timber Harvest during 1st Decade, based on the ASQ (acres)	1,774
Potential Short-term Effects on Timber Industry[5]	
Effect on Timber Volume Under Contract	High
Effect on NEPA-cleared Volume	Low
Effect on Timber Volume in Preparation	Low
Percent of Identified Mineral Tracts and Undiscovered Mineral Areas in Open LUDs with Higher Development Costs	
Percent of Identified Mineral Tracts	36%
Percent of Undiscovered Mineral Areas	57%
Recreation Opportunity Spectrum Classes after 150 Years (millions of acres)	
Primitive and Semi-Primitive Non-Motorized	13.2
Semi-Primitive Motorized	1.4
Roaded Natural and Roaded Modified	2.1

[1] Totals may not add exactly due to rounding.

[2] No lands suitable for timber management and no lands within Timber Production, Modified Landscape, or Scenic Viewshed LUDs are included in inventoried roadless areas under Alternative 1. Approximately 27,000 acres of Experimental Forest are included.

[3] Estimated forest land suitable for timber production represents the mapped suitable forest land minus the estimated portion that is unsuitable, but not mapped as such. The scheduled suitable forest land is the portion of the estimated suitable forest land that is scheduled for harvest by ASQ modeling.

[4] ASQ volumes expressed as annual averages and include sawlog plus utility.

[5] This evaluation provides an indication of potential effects; actual effects would depend on the volume that is under contract when the decision is implemented and whether potentially affected existing sales are cancelled or exempted as part of the decision.

Alternative 2

Framework

Under this alternative, forest management would provide a mix of National Forest uses and activities, but would give additional emphasis to roadless areas, associated fish and wildlife values, and unroaded recreation, tourism, and subsistence opportunities, relative to the current Forest Plan. Timber would be managed within the roaded land base as well as within roadless areas with lower wilderness attribute ratings (primarily those adjacent to developed areas). The vast majority of current roadless areas would remain in a natural condition. A total of 1.9 million acres of the Tongass would be in development LUDs and 14.8 million acres would be in non-development LUDs. The majority of the lands changed to non-development LUDs from development LUDs (in the current Plan) would be designated Semi-Remote Recreation. All areas identified as development LUDs in Alternative 1 would also be development LUDs in this alternative, in addition to other areas. Specific LUD changes under this alternative would include the addition and modification of a number of Geologic Special Interest Areas, recommendations to change the Young Bay Experimental Forest to Semi-Remote Recreation and the Cowee-Davies Creek watersheds from Scenic Viewshed to Experimental Forest, and converting a large area of Remote Recreation LUD north of Juneau to Semi-Remote Recreation. It also would include extensive refinements to the boundaries of the small Old-Growth Reserves, based on a recently completed interagency evaluation.

This alternative would approximately correspond with Scenario 2 (expanded lumber production) of the Brackley et al. (2006) timber demand study.

Desired Conditions

The vast majority of the currently undisturbed areas of the Forest remain in a natural state and most existing roadless areas remain roadless. However, some roadless areas adjacent to existing roaded areas are developed. Old growth conditions prevail on forest lands within roadless areas. A moderate, predictable, and sustainable supply of forest products contributes to a limited Southeast Alaska timber industry, probably based in Ketchikan, Prince of Wales Island, and other communities. A mixture of old growth, recently harvested areas, and various ages of young growth occurs within roaded areas. Recreation, tourism, and subsistence opportunities emphasize natural setting types, although roaded opportunities expand from current conditions.

Land Use Designations

If Alternative 2 is selected, the LUD allocation acres shown in Table 2-5 would result. Figure 2-2 shows the distribution of LUDs across the Tongass under Alternative 2 according to three LUD groups (see Table 2-5 for definitions of the LUD groups). A complete LUD map is provided as the Alternative 2 map in the *Map Section* of the CD version of this EIS or in the *Map Packet* accompanying the EIS hard copy.

Management Prescriptions and Standards and Guidelines

Under Alternative 2, the management prescriptions and standards and guidelines identified in the Final Proposed Forest Plan would be adopted. These are generally the same as the management prescriptions and standards and guidelines in the current Forest Plan; however, a number of changes and refinements are proposed. A summary of the main changes to the current Forest Plan is provided above in the section titled “Final Proposed Forest Plan.”

Selected Outputs

Table 2-6 displays selected outputs and other measures associated with this alternative.

Table 2-5
Land Use Designations for Alternative 2[1]

Land Use Designation	Acres Allocated	Net Change from Current Forest Plan Acres[2]
Wilderness LUD Group		
Wilderness	2,637,292	0

Recreation Opportunity Spectrum Classes after 150 Years (millions of acres)	
Primitive and Semi-Primitive Non-Motorized	12.8
Semi-primitive Motorized	1.3
Roaded Natural and Roaded Modified	2.6

[1] Totals may not add exactly due to rounding.

[2] Estimated forest land suitable for timber production represents the mapped suitable forest land minus the estimated portion that is unsuitable, but not mapped as such. The scheduled suitable forest land is the portion of the estimated suitable forest land that is scheduled for harvest by ASQ modeling.

[3] ASQ volumes expressed as annual averages and include sawlog plus utility.

[4] This evaluation provides an indication of potential effects; actual effects would depend on the volume that is under contract when the decision is implemented and whether potentially affected existing sales are cancelled or exempted as part of the decision.

Alternative 3

Framework

Under Alternative 3, forest management would provide a mix of National Forest uses and activities, but would give some additional emphasis to roadless areas, associated fish and wildlife values, and unroaded recreation, tourism, and subsistence opportunities, relative to the current Forest Plan. Timber would be managed within the roaded land base as well as within additional roadless areas; but these additional areas would not include the high value roadless areas identified in the 1999 Record of Decision (USDA Forest Service 1999) as the 18 Areas of Special Interest or the 23 areas proposed for wilderness in H.R. 987. The vast majority of current roadless areas would remain in a natural condition. A total of 2.8 million acres of the Tongass would be in development LUDs and 14.0 million acres would be in non-development LUDs. The majority of the lands changed to non-development LUDs from development LUDs (in the current Plan) would be designated Semi-Remote Recreation. All areas identified as development LUDs in Alternative 2 would also be development LUDs in this alternative, in addition to other areas. Specific LUD changes under this alternative would include the addition and modification of a number of Geologic Special Interest Areas, recommendations to change the Young Bay Experimental Forest to Semi-Remote Recreation and the Cowee-Davies Creek watersheds from Scenic Viewshed to Experimental Forest, and converting a large area of Remote Recreation LUD north of Juneau to Semi-Remote Recreation. It also would include extensive refinements to the boundaries of the small Old-Growth Reserves, based on a recently completed interagency evaluation.

This alternative would approximately correspond with Scenario 3 (medium integrated industry) of the Brackley et al. (2006) timber demand study. It is similar to Alternative 5 of the 2003 SEIS in terms of the areas allocated to non-development LUDs.

Desired Conditions

The vast majority of the currently undisturbed areas of the Forest remain in a natural state and most existing roadless areas remain roadless. However, over half of the roadless areas to be developed under the current Forest Plan are developed. Old growth conditions prevail on forest lands within the roadless areas. A predictable and sustainable supply of forest products contributes to a medium integrated timber industry in Southeast Alaska, probably based in Ketchikan, Prince of Wales Island, Wrangell, and Hoonah. A mixture of old growth, recently harvested areas, and various ages of young growth occurs within roaded areas. Recreation, tourism, and subsistence opportunities occur in natural setting types, but roaded opportunities are considerably expanded from current conditions, although not as much as under the current Plan.

Land Use Designations

If Alternative 3 is selected, the LUD allocation acres shown in Table 2-7 would result. Figure 2-3 shows the distribution of LUDs across the Tongass under Alternative 3 according to three LUD groups (see Table 2-7 for definitions of the LUD groups). A complete LUD map is provided as the Alternative 3 map in the *Map Section* of the CD version of this EIS or in the *Map Packet* accompanying the EIS hard copy.

Management Prescriptions and Standards and Guidelines

Under Alternative 3, the management prescriptions and standards and guidelines identified in the Final Proposed Forest Plan would be adopted. These are generally the same as the management prescriptions and standards and guidelines in the current Forest Plan; however, a number of changes and refinements are proposed. A summary of the main changes to the current Forest Plan is provided above in the section titled “Final Proposed Forest Plan.”

Selected Outputs

Table 2-8 displays selected outputs and other measures associated with this alternative.

Table 2-7
Land Use Designations for Alternative 3[1]

Primitive and Semi-Primitive Non-Motorized	12.4
Semi-Primitive Motorized	1.3
Roaded Natural and Roaded Modified	3.1

1 Totals may not add exactly due to rounding.
2 Estimated forest land suitable for timber production represents the mapped suitable forest land minus the estimated portion that is unsuitable, but not mapped as such. The scheduled suitable forest land is the portion of the estimated suitable forest land that is scheduled for harvest by ASQ modeling.
3 ASQ volumes expressed as annual averages and include sawlog plus utility.
4 This evaluation provides an indication of potential effects; actual effects would depend on the volume that is under contract when the decision is implemented and whether potentially affected existing sales are cancelled or exempted as part of the decision.

Alternative 4

Framework

Under Alternative 4, forest management would provide a mix of National Forest uses and activities, but would give additional emphasis to timber management and associated economic stability of Southeast Alaska communities, relative to the current Forest Plan. Timber would be managed within an area expanded beyond the current Forest Plan. The vast majority of current roadless areas would remain in a natural condition; however, the majority of roadless areas that contain substantial productive old growth (POG), outside of wilderness, would be developed. A total of 4.7 million acres of the Tongass would be in development LUDs and 12.0 million acres would be in non-development LUDs. Almost all areas identified as development LUDs in Alternative 5 would also be development LUDs in this alternative, in addition to other areas. Specific LUD changes under this alternative would include the addition and modification of a number of Geologic Special Interest Areas, recommendations to change the Young Bay Experimental Forest to Semi-remote Recreation and the Cowee-Davies Creek watersheds from Scenic Viewshed to Experimental Forest, and converting a large area of Remote Recreation LUD north of Juneau to Semi-Remote Recreation.

This alternative would approximately correspond with Scenario 4 (high integrated industry) of the Brackley et al. (2006) timber demand study. It is similar to Alternative 6 of the 1997 FEIS.

Desired Conditions

The vast majority of the currently undisturbed areas of the Forest remain in a natural state and most existing roadless areas remain roadless. However, all of the roadless areas to be developed under the current Forest Plan are developed along with some additional roadless areas. Old growth conditions prevail on forest lands within roadless areas. The Tongass produces a predictable and sustainable supply of forest products that contributes to a high integrated timber industry in Southeast Alaska, probably based in Ketchikan, Prince of Wales Island, Wrangell, Hoonah, and other communities; however, private and state lands also contribute to satisfying the demand for timber. A mixture of old growth, recently harvested areas, and various ages of young growth occurs within roaded areas. Recreation, tourism, and subsistence opportunities occur in natural setting types, but roaded opportunities are substantially expanded from current conditions.

Land Use Designations

If Alternative 4 is selected, the LUD allocation acres shown in Table 2-9 would result. Figure 2-4 shows the distribution of LUDs across the Tongass under Alternative 4 according to three LUD groups (see Table 2-9 for definitions of the LUD groups). A complete LUD map is provided as the Alternative 4 map in the *Map Section* of the CD version of this EIS or in the *Map Packet* accompanying the EIS hard copy.

Management Prescriptions and Standards and Guidelines

Under Alternative 4, the management prescriptions and standards and guidelines identified in the Final Proposed Forest Plan would be adopted, with the exceptions noted below. The Alternative 4 management prescriptions and standards and guidelines are generally the same as those in the current Forest Plan; however, a number of changes and refinements are proposed. The summary, presented above (Final Proposed Forest Plan section), of the main changes to the current Forest Plan, reflects the proposal under Alternative 4, with the following exceptions:

- The Old-Growth Habitat LUD (and the system of large, medium, and small old-growth reserves) is applied only within four biogeographic provinces (Northern Prince of Wales Island, Kupreanof/Mitkof Islands, Dall Island, Northeast Chichagof Island) plus several individual reserves outside of these provinces

- In Value Comparison Units (VCUs) not within the four biogeographic provinces identified above, retain a minimum of 33 percent of the productive forest land in an old-growth forest condition
- The goshawk foraging habitat standard and guideline, the high-value marten habitat standard and guideline, and the proposed Legacy standard and guideline would not be implemented

Selected Outputs

Table 2-10 displays selected outputs and other measures associated with this alternative.

Table 2-9
Land Use Designations for Alternative 4[1]

1 Totals may not add exactly due to rounding.
2 Estimated forest land suitable for timber production represents the mapped suitable forest land minus the estimated portion that is unsuitable, but not mapped as such. The scheduled suitable forest land is the portion of the estimated suitable forest land that is scheduled for harvest by ASQ modeling.
3 ASQ volumes expressed as annual averages and include sawlog plus utility.
4 This evaluation provides an indication of potential effects; actual effects would depend on the volume that is under contract when the decision is implemented and whether potentially affected existing sales are cancelled or exempted as part of the decision.

Alternative 5

Framework

This is the No Action alternative. It represents a continuation of the current Forest Plan and would result in a mix of National Forest uses and activities. Timber would be managed in an area more extensive than under Alternative 3, but less extensive than under Alternative 4. The vast majority of current roadless areas would remain in a natural condition; however, the majority of roadless areas that contain substantial POG, outside of wilderness, would be partially developed. A total of 3.6 million acres of the Tongass would be in development LUDs and 13.2 million acres would be in non-development LUDs. This alternative is the same as the current Forest Plan (Alternative 11 from the 1997 FEIS plus amendments).

Desired Conditions

The vast majority of the currently undisturbed areas of the Forest remain in a natural state and most existing roadless areas remain roadless. Old growth conditions prevail on forest lands within roadless areas. A predictable and sustainable supply of forest products contribute to a limited integrated timber industry in Southeast Alaska, probably based in Ketchikan, Prince of Wales Island, Wrangell, and Hoonah. There would be sufficient volume under this alternative to support the existing sawmills. There would also be sufficient volume to support one or more veneer plants or an MDF or other chip-related operation, but probably not both. A mixture of old growth, recently harvested areas, and various ages of young growth occurs within roaded areas. Recreation, tourism, and subsistence opportunities occur in natural setting types, but roaded opportunities are considerably expanded from current conditions.

Land Use Designations

If Alternative 5 is selected, the LUD allocation acres shown in Table 2-11 would result. Figure 2-5 shows the distribution of LUDs across the Tongass under Alternative 5 according to three LUD groups (see Table 2-11 for definitions of the LUD groups). A complete LUD map is provided as the Alternative 5 map in the *Map Section* of the CD version of this EIS or in the *Map Packet* accompanying the EIS hard copy.

Standards and Guidelines

Under Alternative 5, the standards and guidelines identified in the current Forest Plan would be adopted. These represent the 1997 Forest Plan with amendments (USDA Forest Service 1997b).

Selected Outputs

Table 2-12 displays selected outputs and other measures associated with this alternative.

Table 2-11
Land Use Designations for Alternative 5[1]

Land Use Designation	Acres Allocated	Net Change from Current Forest Plan Acres[2]

Modified Landscape	601,362	0
Timber Production	2,510,298	0
Total for Development LUD Group	**3,605,974**	**0**
Total National Forest System Lands	**16,773,808**	**0**

[1] When more than one LUD is applied to the same area, such as a Special Interest Area within Wilderness, only the acreage of the more restrictive LUD is included, except that total Wilderness, Wilderness National Monument, and LUD II acres are always shown. The acreage for the Minerals LUD would be 170,514; these acres are not included in the table because the Minerals LUD is an overlay. No acreages have been calculated for the Transportation and Utility System LUD because it is a series of corridors with undefined width and imprecise locations. Totals may not exactly equal the sum of individual entries due to rounding.

[2] These changes from current Forest Plan acres are the differences from the decisions made in the 1997 Tongass Forest Plan Revision ROD, as amended, which is represented by Alternative 5.

[3] The majority of the National Monument acres are wilderness; only 166,942 acres are non-wilderness.

Figure 2-5
Wilderness, Natural Setting, and Development LUDs on the Tongass National Forest under Alternative 5

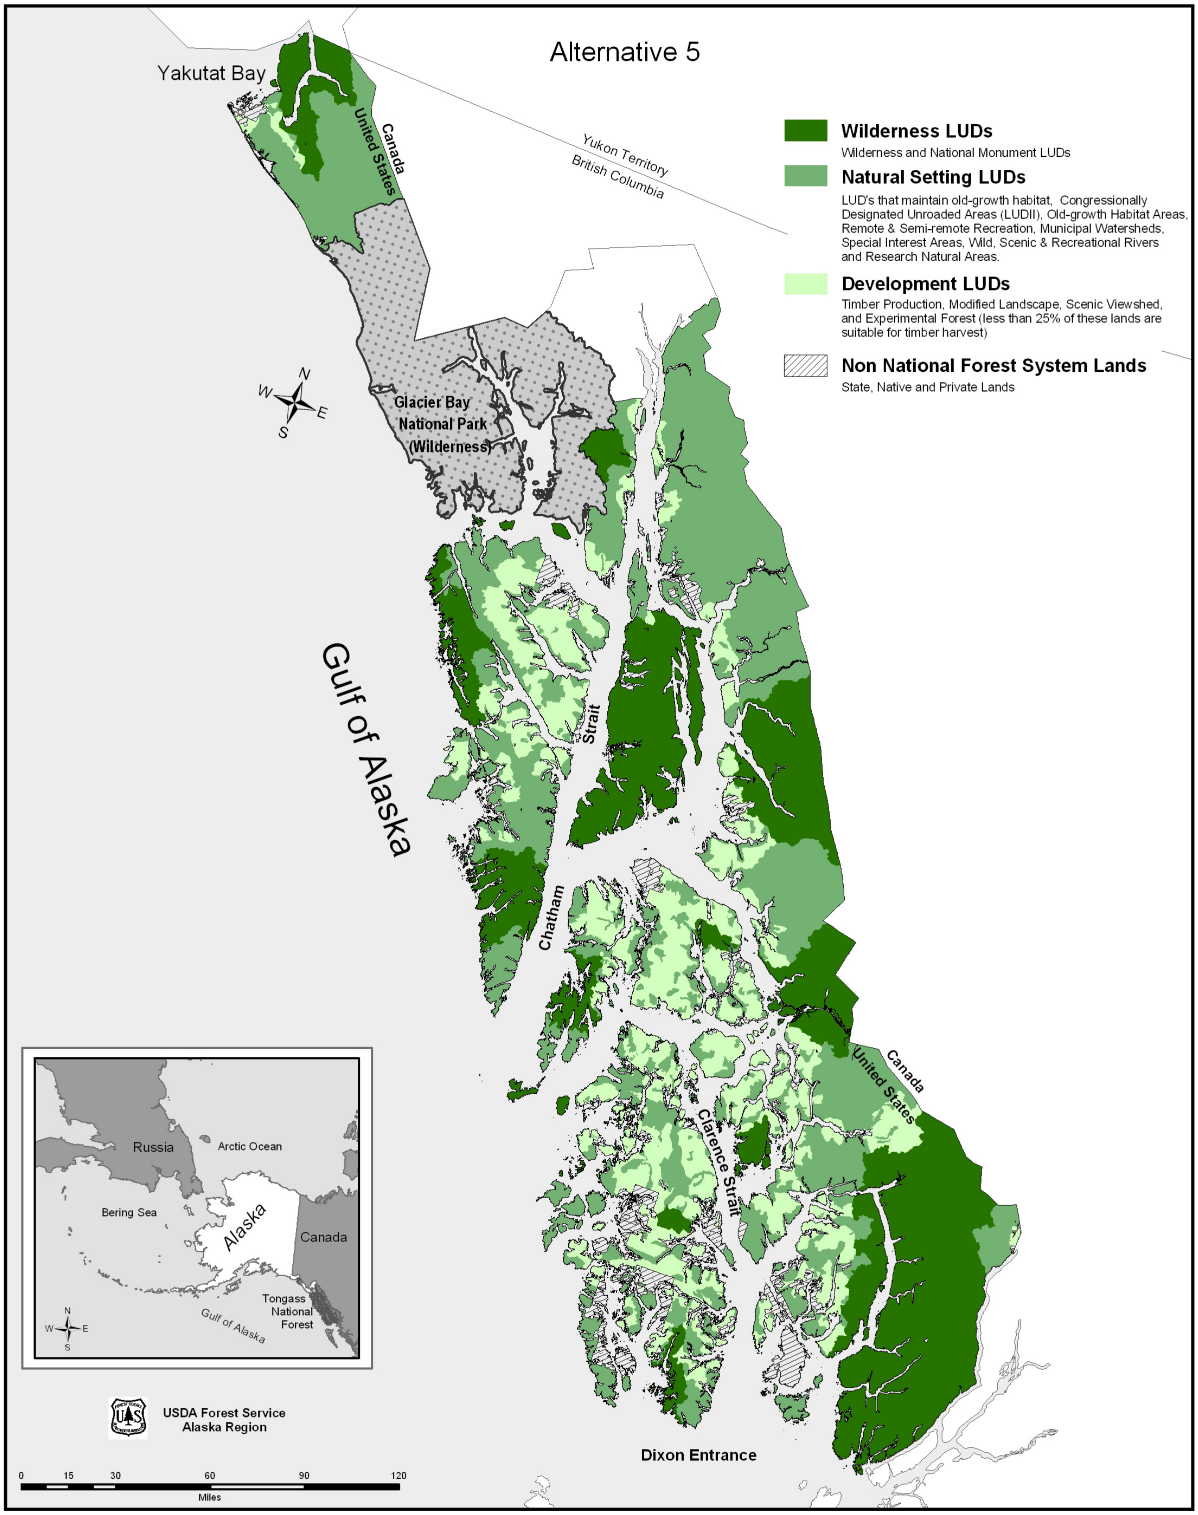

Table 2-12
Selected Outputs and Measures Associated with Alternative 5[1]

Resource/Category	Output/Measure
Percent in Wilderness LUD Group	35%
Percent in Natural Setting LUD Group	43%
Percent in Development LUD Group	21%
Amount of Development LUDs in Inventoried Roadless Areas (millions of acres)	2.4
Percent of Current Productive Old Growth Protected in Reserves (Wilderness/Nat. Mon. and Natural Setting LUDs)	71%
Productive Old Growth after 100+ Years (millions of acres)	4.5
Estimated Forest Land Suitable for Timber Production (acres)[2]	757,000
Scheduled Suitable Forest Land (acres)[2]	702,000
Allowable Sale Quantity or ASQ (millions of board feet)[3]	
1st Decade ASQ	267
2nd Decade ASQ	267
Maximum New Road Construction after 100+ Years (miles)	3,874
Maximum Average Annual Timber Harvest during 1st Decade, based on the ASQ (acres)	10,308
Potential Short-term Effects on Timber Industry[4]	
Effect on Timber Volume Under Contract	None
Effect on NEPA-cleared Volume	None
Effect on Timber Volume in Preparation	None
Percent of Identified Mineral Tracts and Undiscovered Mineral Areas in Open LUDs with Higher Development Costs	
Percent of Identified Mineral Tracts	29%
Percent of Undiscovered Mineral Areas	41%
Recreation Opportunity Spectrum Classes after 150 Years (millions of acres)	
Primitive and Semi-Primitive Non-Motorized	11.9
Semi-Primitive Motorized	1.3
Roaded Natural and Roaded Modified	3.6

1 Totals may not add exactly due to rounding.

2 Estimated forest land suitable for timber production represents the mapped suitable forest land minus the estimated portion that is unsuitable, but not mapped as such. The scheduled suitable forest land is the portion of the estimated suitable forest land that is scheduled for harvest by ASQ modeling. Slight differences in suitable acres between Alternative 5 (shown above) and Alternative 11 of the 1997 Final EIS are caused by: 1) changes in ownership, 2) changes in LUDs, and 3) the use of different estimation methods.

3 ASQ volumes expressed as annual averages and include sawlog plus utility.

4 This evaluation provides an indication of potential effects; actual effects would depend on the volume that is under contract when the decision is implemented and whether potentially affected existing sales are cancelled or exempted as part of the decision.

Alternative 6

Framework

This is the Proposed Action alternative. It is very similar to the Alternative 5 (No Action) alternative in terms of LUD allocations; however, it includes extensive refinements to the boundaries of the small Old-Growth Reserves (based on a recently completed interagency evaluation), new Geologic Special Interest Areas, a new Experimental Forest, the conversion of a large area of Remote Recreation LUD north of Juneau to Semi-Remote Recreation, and other minor LUD refinements. Timber would be managed in an area more extensive than under Alternative 3, but less extensive than under Alternative 4. The vast majority of current roadless areas would remain in a natural condition; however, the majority of roadless areas that contain substantial POG, outside of wilderness, would be partially developed. A total of 3.5 million acres of the Tongass would be in development LUDs and 13.3 million acres would be in non-development LUDs. Specific LUD changes under this alternative would include the addition and modification of a number of Geologic Special Interest Areas, recommendations to change the Young Bay Experimental Forest to Semi-remote Recreation and the Cowee-Davies Creek watersheds from Scenic Viewshed to Experimental Forest, and converting a large area of Remote Recreation LUD north of Juneau to Semi-Remote Recreation. It also would include extensive refinements to the boundaries of the small Old-Growth Reserves, based on a recently completed interagency evaluation.

This alternative is similar to Alternative 11 of the 1997 FEIS.

Desired Conditions

The vast majority of the currently undisturbed areas of the Forest remain in a natural state and most existing roadless areas remain roadless. Old growth conditions prevail on forest lands within roadless areas. A predictable and sustainable supply of forest products contribute to a limited integrated timber industry in Southeast Alaska, probably based in Ketchikan, Prince of Wales Island, Wrangell, and Hoonah. There would be sufficient volume under this alternative to support the existing sawmills. There would also be sufficient volume to support one or more veneer plants or an MDF or other chip-related operation, but probably not both. Populations of wildlife dependent on old-growth and/or unroaded habitats have a moderately high likelihood of being maintained as viable and well-distributed across the Tongass. A mixture of old growth, recently harvested areas, and various ages of young growth occurs within roaded areas. Recreation, tourism, and subsistence opportunities occur in natural setting types, but roaded opportunities are considerably expanded from current conditions.

Land Use Designations

If Alternative 6 is selected, the LUD allocation acres shown in Table 2-13 would result. Figure 2-6 shows the distribution of LUDs across the Tongass under Alternative 6 according to three LUD groups (see Table 2-13 for definitions of the LUD groups). A complete LUD map is provided as the Alternative 6 map in the *Map Section* of the CD version of this EIS or in the *Map Packet* accompanying the EIS hard copy.

Management Prescriptions and Standards and Guidelines

Under Alternative 6, the management prescriptions and standards and guidelines identified in the Final Proposed Forest Plan would be adopted. These are generally the same as the management prescriptions and standards and guidelines in the current Forest Plan; however, a number of changes and refinements are proposed. A summary of the main changes to the current Forest Plan is provided above in the section titled “Final Proposed Forest Plan.”

Selected Outputs

Table 2-14 displays selected outputs and other measures associated with this alternative.

Table 2-13
Land Use Designations for Alternative 6[1]

Land Use Designation	Acres Allocated	Net Change from Current Forest Plan Acres[2]
Wilderness LUD Group		
Wilderness	2,637,292	0
National Monument[3]	3,278,734	0
Total for Wilderness LUD Group	**5,916,026**	**0**
Natural Setting LUD Group		
LUD II	721,002	0
Research Natural Area	26,093	0
Old Growth[4]	1,221,173	38,749
Special Interest Area[4]	221,176	46,712
Enacted Municipal Watershed	45,226	0
Wild, Scenic, and Recreational River	117,319	0
Remote Recreation	2,033,665	(97,390)
Semi-Remote Recreation	3,014,704	160,479
Total for Natural Setting LUD Group	**7,400,359**	**148,551**
Development LUD Group		
Experimental Forest	31,405	14,309
Scenic Viewshed	442,101	(35,118)
Modified Landscape	590,338	(11,024)
Timber Production	2,393,576	(116,721)
Total for Development LUD Group	**3,457,420**	**(148,551)**
Total National Forest System Lands	**16,773,806**	**0**

[1] When more than one LUD is applied to the same area, such as a Special Interest Area within Wilderness, only the acreage of the more restrictive LUD is included, except that total Wilderness, Wilderness National Monument, and LUD II acres are always shown. The acreage for the Minerals LUD would be 249,570; these acres are not included in the table because the Minerals LUD is an overlay. No acreages have been calculated for the Transportation and Utility System LUD because it is a series of corridors with undefined width and imprecise locations. Totals may not exactly equal the sum of individual entries due to rounding.

[2] These changes from current Forest Plan acres are the differences from the decision made in the 1997 Tongass Forest Plan Revision ROD, as amended, which is represented by Alternative 5.

[3] The majority of the National Monument acres are wilderness; only 166,942 acres are non-wilderness.

[4] Small old-growth reserves and Special Interest Area LUDs increased relative to Alternative 5; however, they overlap extensively, especially on Heceta, Kosciusko, and northeast Chichagof Islands, and the acreages where they overlap were counted with Special Interest Areas.

Figure 2-6
Wilderness, Natural Setting, and Development LUDs on the Tongass National Forest under Alternative 6

Primitive and Semi-Primitive Non-Motorized	12.0
Semi-Primitive Motorized	1.3
Roaded Natural and Roaded Modified	3.5

1 Totals may not add exactly due to rounding.
2 Estimated forest land suitable for timber production represents the mapped suitable forest land minus the estimated portion that is unsuitable, but not mapped as such. The scheduled suitable forest land is the portion of the estimated suitable forest land that is scheduled for harvest by ASQ modeling.
3 ASQ volumes expressed as annual averages and include sawlog plus utility.
4 This evaluation provides an indication of potential effects; actual effects would depend on the volume that is under contract when the decision is implemented and whether potentially affected existing sales are cancelled or exempted as part of the decision.

Alternative 7

Framework

Under Alternative 7, forest management would provide a mix of National Forest uses and activities, but would give much additional emphasis to timber management, relative to the current Forest Plan. Timber would be managed on a considerably expanded land base compared with the current Forest Plan. The vast majority of current roadless areas would remain in a natural condition; however, the majority of roadless areas that contain substantial POG outside of Wilderness, would be fully developed. A total of 5.0 million acres of the Tongass would be in development LUDs and 11.7 million acres would be in non-development LUDs. Almost all areas identified as development LUDs in Alternative 5 would also be development LUDs in this alternative, in addition to other areas. Specific LUD changes under this alternative would include the addition and modification of a number of Geologic Special Interest Areas and recommendations to change the Young Bay Experimental Forest to Semi-remote Recreation and the Cowee-Davies Creek watersheds from Scenic Viewshed to Experimental Forest.

This alternative is similar to Alternative 2 of the 1997 FEIS.

Desired Conditions

The vast majority of the currently undisturbed areas of the Forest remain in a natural state and most existing roadless areas remain roadless. However, all of the roadless areas to be developed under the current Forest Plan are developed along with additional roadless areas. Old growth conditions prevail on forest lands within roadless areas. The Tongass produces a predictable and sustainable supply of forest products that completely satisfies the demand from a high integrated timber industry in Southeast Alaska, probably based in Ketchikan, Prince of Wales Island, Wrangell, Hoonah, and other communities. Timber from private and state lands is not required to satisfy timber demand. A mixture of old growth, recently harvested areas, and various ages of young growth occurs within roaded areas. Recreation, tourism, and subsistence opportunities occur in natural setting types, but roaded opportunities are substantially expanded from current conditions.

Land Use Designations

If Alternative 7 is selected, the LUD allocation acres shown in Table 2-15 would result. Figure 2-7 shows the distribution of LUDs across the Tongass under Alternative 7 according to three LUD groups (see Table 2-15 for definitions of the LUD groups). A complete LUD map is provided as the Alternative 7 map in the *Map Section* of the CD version of this EIS or in the *Map Packet* accompanying the EIS hard copy.

Management Prescriptions and Standards and Guidelines

Under Alternative 7, the standards and guidelines identified in the current Forest Plan would be adopted, with the exceptions noted below. The current Forest Plan represents the 1997 Forest Plan with amendments (USDA Forest Service 1997b). The exceptions include:

- The Beach and Estuary Fringe buffer is changed to 500 feet. along the beach fringe and 1,000 feet. around estuaries.
- The Riparian Standards and Guidelines are modified so that buffers are not required along Class III streams.
- The Old-Growth Habitat LUD and its management prescription is not used and is deleted.
- The goshawk foraging habitat standard and guideline, the high-value marten habitat standard and guideline, and the proposed Legacy standard and guideline would not be implemented.
- The goshawk nesting standard and guideline would not be implemented.

Selected Outputs

Table 2-16 displays selected outputs and other measures associated with this alternative.

Table 2-15

[4] This evaluation provides an indication of potential effects; actual effects would depend on the volume that is under contract when the decision is implemented and whether potentially affected existing sales are cancelled or exempted as part of the decision.

Comparison of the Alternatives

This section briefly compares the environmental consequences of the seven alternatives with respect to the key issues described in Chapter 1. This comparison is based on the effects analysis presented in Chapter 3.

Prior to presenting the effects comparison, four tables and a figure are displayed to help the reader compare the differences among the alternatives. Table 2-17 and Figure 2-8 summarize the LUD allocations of the alternatives using LUD Group combinations. The four LUD Groups combine the individual LUDs in terms of similarities in management and/or potential effects as described in the *Introduction* to Chapter 3. The other components that help define each alternative beyond LUD allocations are summarized in Table 2-18.

Table 2-19 displays some of the key indicators or measures that are used to quantitatively compare the alternatives relative to the key issues. In addition, Table 2-20, located at the end of this chapter, represents a "Summary of Effects Matrix." This table allows the reader to compare the effects of the alternatives on essentially all resource areas simultaneously, so that a cumulative picture of the net effects can be obtained. This table presents many quantitative measures, but it uses qualitative comparisons where quantitative measures are not feasible. In this regard, it may be used to help consider the net public benefits associated with each alternative.

Key Issue 1 – Protection of high value roadless areas from road development and timber harvest activity on the Tongass National Forest is of local and national importance, particularly for wildlife and biodiversity, recreation, and tourism.

The Tongass includes very large undeveloped land areas, with several portions of the Forest consisting of contiguous roadless areas that exceed one million acres (and are often many times larger than that) and represent large, unfragmented blocks of wildlife habitat. This scale of roadless lands is not available elsewhere in the National Forest System, except on the Chugach National Forest.

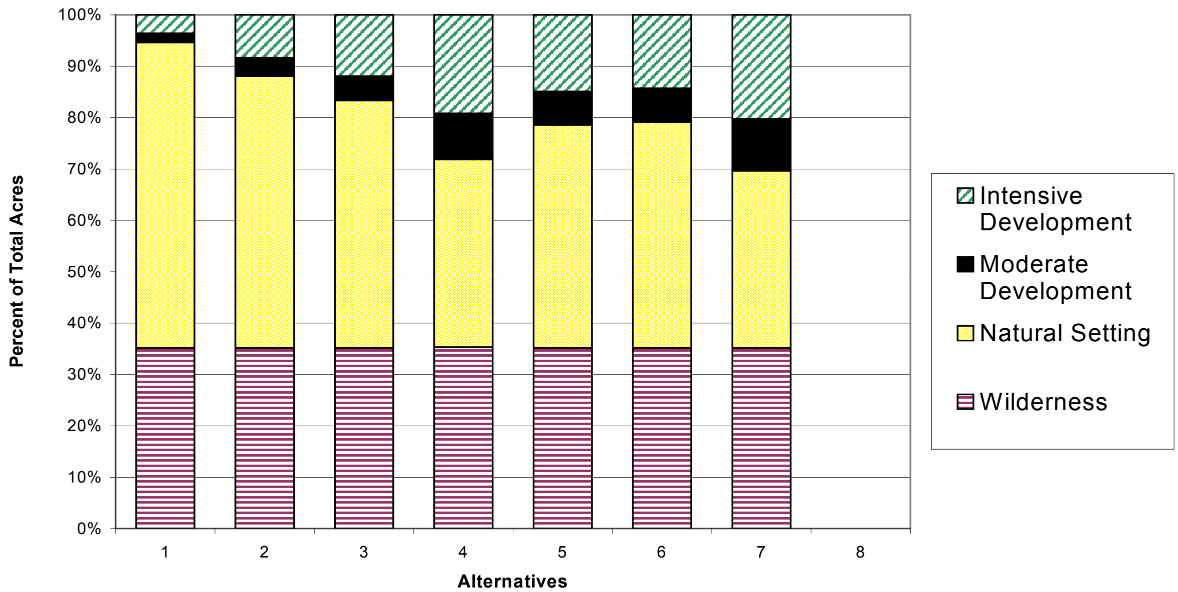
Roadless areas are considered important because of their wildlife habitat and recreation values and their importance for tourism. They are also important because of the passive use values and ecosystem services values they provide. Passive use values represent the value that individuals assign to a resource independent of their use of that resource and typically include existence, option, and bequest values.

Table 2-17
Land Use Designation Group Comparison by Alternative (million acres)[1]

Alternative	Wilderness[2]	Natural Setting	Moderate Development	Intensive Development
1	5.9	10.0	0.3	0.6
2	5.9	8.9	0.6	1.4
3	5.9	8.1	0.8	2.0
4	5.9	6.1	1.5	3.2
5	5.9	7.3	1.1	2.5
6	5.9	7.4	1.1	2.4
7	5.9	5.8	1.7	3.4

[1] LUD Group combinations are described in the *Introduction* to Chapter 3 (Table 3.1-1).
[2] Wilderness LUD group includes 166.942 acres of Nonwilderness National Monument.
Note: Roadless area acreages are correlated with, but not the same as the LUD Group acreages. For example, some roads exist within portions of some Natural Setting LUDs and no roads exist in many areas of development LUDs.

Figure 2-8
Land Use Designation Group Comparison by Alternative (percent)



Direct Effects on Roadless Areas

The Tongass National Forest is about 91 percent roadless, including wilderness. Only small areas where communities are developing, or where road construction and timber harvest have occurred, are "developed" to any noticeable degree. Developed areas and small unroaded areas (not included in inventoried roadless areas) cover about 1.51 million acres, or about 9 percent of the Tongass, wilderness covers about 5.75 million acres, or about 34 percent, and inventoried roadless areas (outside of wilderness) cover about 9.51 million acres, or about 57 percent.

Alternative 1 is designed to avoid inventoried roadless areas. Because of this, after 100 years or more (and full development of these LUD areas) 91 percent of the Tongass and 85 percent of Southeast Alaska (all Alaska lands southeast of Yakutat Bay) would still be in roadless or wilderness.

Alternatives 2 and 3 would progressively enter more roadless areas with 0.8 million acres and 1.7 million acres of development LUDs in roadless areas, respectively. Alternative 2 would ultimately result in 87 percent of the Tongass and 82 percent of Southeast Alaska in roadless or wilderness and Alternative 3 would result in 83 percent and 79 percent.

Next in progression into roadless areas, Alternatives 5 and 6 would include 2.4 and 2.3 million acres of development LUDs in roadless, respectively. Alternative 5 would ultimately result in 80 percent of the Tongass and 76 percent of Southeast Alaska being in roadless or wilderness. These percentages would be 81 and 77 for Alternative 6.

Finally, Alternatives 4 and 7 both enter roadless areas to a higher degree. Alternative 4 would have 3.4 million acres of development LUDs in roadless and Alternative 7 would have 3.7 million. After 100 years or more of implementation, Alternative 4 would result in 76 percent of the Tongass and 73 percent of Southeast Alaska and Alternative 7 would result in 75 percent of the Tongass and 72 percent of Southeast Alaska continuing as roadless or in wilderness.

Distribution of Roadless Areas

Significant acreages of roadless areas would remain in all biogeographic provinces under all alternatives; however, some would maintain a higher percentage than others. Under Alternatives 1 and 2, none of the 21 biogeographic provinces within the Tongass boundary would contain less than 50 percent of their areas in Non-development LUDs. Alternative 1 would have 17 of the 21 provinces containing 90 percent or more acreage in non-development LUDs and Alternative 2 would have 13 provinces.

Other S&G Changes in Proposed Forest Plan	Yes	Yes	Yes	Yes	No	Yes	No

[1] Identifies the previous Forest Plan NEPA document and the specific alternative that the current alternative is largely based on (1997 = the 1997 FEIS; 2003 = 2003 SEIS). However, many changes have been made.
[2] This component refers to the use of the system of old-growth habitat reserves to address wildlife viability. Such a system is in addition to reserves that already exist, such as within Wilderness or Legislated LUD II areas.

Definitions
Reserves:
All = Large, Medium, and Small reserves identified in the current Forest Plan
4 Biogeo. Provinces = N. POW, Kupreanof/Mitkof, Dall Island, NE Chichagof, and individual reserves (Myers Chuck, Lake Eva, Wright Lake).
S&Gs = Standards and Guidelines
VCU = Value Comparison Unit (roughly a watershed)

* 21 Biogeographic Provinces inside the Forest Boundary plus 2 outside (Chilkat River Complex and Glacier Bay/Fairweather Range)

Alternative 3 would have two biogeographic provinces and Alternatives 5 and 6 would have three provinces with less than 50 percent their acreage in non-development LUDs. The lowest percentage would be for the Etolin Island and Vicinity province with 43 percent under Alternative 3 and for the Kupreanof/Mitkof Island province with 36 percent under Alternative 5 and 39 percent under Alternative 6. Alternative 3 would have 9 of the 21 provinces and Alternative 5 and 6 would have 6 of the 21 provinces with 90 percent or more of their acreage in non-development LUDs.

Alternatives 4 and 7 would each result in five biogeographic provinces with less than 50 percent in non-development LUDs. The lowest percentage would be for the Etolin Island and Vicinity province with 20 percent under Alternative 4 and for the Kupreanof/Mitkof Island province with 18 percent under Alternative 7. Alternatives 4 and 7 would have 6 of the 21 provinces containing 90 percent or more of their acreage in non-development LUDs.

Key Issue 2 – The Tongass National Forest needs to provide a sufficient timber supply to meet the market demand and help maintain a vibrant economy in Southeast Alaska.

Timber from the Tongass National Forest is the main source of raw materials for the region's wood products industry.

Demand may be thought of as the different amounts of a product buyers are willing to purchase at different prices. Demand is not a single number, but instead a series of price-quantity relationships. The same is true of supply. It is the combination of supply and demand that determines the quantity and price of goods produced and consumed.

Accurately projecting future demand is difficult. Market demand for Southeast Alaska timber and wood products depends upon numerous difficult to predict factors, including changes in technology, growth and exchange rates in key markets, changes in consumer tastes and preferences, as well as developments in other producing regions whose products compete with those of Alaska.

The average timber sale on the Tongass includes spruce, hemlock, and cedar and results in a variety of log grades and species. In most forested conditions, the tree species, tree sizes and tree quality are all mixed together. When a timber sale is purchased by a sawmill owner, they are usually required to purchase all of the volume in that sale regardless of the composition. At present, none of the purchasers are set up to efficiently process all grade and species from such sales, nor is the local industry set up to process all of the components of the timber sales. In the absence of a facility to use utility and lower grade logs, a timber sale must be sustained solely on the profits made from the higher grade sawlogs, even though the operator must harvest and pay for the lower grade logs.

It should be noted that the Alaska Regional Forester (Region 10) signed a new policy in March 2007 that approved limited interstate shipments of unprocessed Sitka spruce and western hemlock. This policy is expected to increase the utilization of timber harvested on the Tongass and improve overall timber sale economics by providing a market for smaller diameter and low grade material that cannot be processed profitably by sawmills in Southeast Alaska.

The wood products analysis prepared for this EIS is divided into long- and short-term effects. The long-term effects analysis evaluates the alternatives with respect to a) the projections developed by the Pacific Northwest Research Station of the Forest Service, and b) current production levels, installed capacity, and the minimum volumes required by various processing facilities. These benchmarks are used to evaluate the long-term effects of the alternatives. Long-term effects are assessed based on the ASQ projected under each alternative.

The short-term effects analysis discusses three key components of the "timber pipeline": volume under contract, NEPA-cleared volume (i.e., sales that have approved NEPA documents but have not yet been sold), and timber volume in preparation (i.e., proposed sales that are currently being evaluated under the NEPA process).

Long-Term Effects

PNW Projections. The Forest Service commissioned the Pacific Northwest Research Station to determine the maximum amount of timber product volume that could be sold over time (planning cycle market demand) and to develop a series of demand estimates as the industry grew to meet this output level. This resulted in a "derived demand" analysis that projected various demand figures for four scenarios based upon differing assumptions about future markets and future processing facilities in Southeast Alaska (Brackley et al. 2006). These future visions of the Southeast Alaska wood products industry are hypothetical and presented here to illustrate the type of developments that might take place in cases where different volumes are made available for harvest. The transition from one scenario to the next involves new private investment and market development. A key factor in attracting new investment is whether or not a supply of timber "shelf volume" is available for purchase.

Alternatives 1 through 4 were designed to correspond with Scenarios 1 through 4, respectively, while also responding to other concerns. The discrepancy between the second decade ASQs for Alternatives 1 and 2 and projected demand for 2022 under Scenarios 1 and 2 reflects these other concerns. These scenarios are briefly summarized in the following paragraphs, along with the ability of the alternatives to meet each scenario in 2022.

Scenario 1 – Limited Lumber Production. This scenario approximates the status of the timber industry in Southeast Alaska at the time that the Brackley et al. study was completed. Total derived demand is projected to be 68 MMBF in 2022 under this scenario. It is likely that this volume would be primarily logs from more economical (NIC I) lands.

Alternative 1, with a projected total output of 49 MMBF, could not provide sufficient volume to meet this scenario as currently modeled.

Alternatives 2, 3, 4, 5, 6, and 7 could all provide sufficient volume to meet this scenario in 2022.

Scenario 2 – Expanded Lumber Production. This scenario also projects that only higher value logs are processed, with limited new investments in the existing mills in Southeast Alaska. Total derived demand is projected to be 187 MMBF in 2022 under this scenario. As in Scenario 1, it is likely that this volume would be primarily higher value logs from the more economical (NIC I) lands.

Alternatives 1 and 2, with projected total outputs of 49 MMBF and 151 MMBF, respectively, could not provide sufficient volume to meet this scenario.

Alternatives 3, 4, 5, 6, and 7 could all provide sufficient volume to meet this scenario.

Scenario 3 – Medium Integrated Industry. This scenario builds on Scenario 2 and would establish processing capacity to fully utilize sawlogs and low grade and utility logs from federal and state timber sales. Under this scenario the current sawlog milling capacity would operate efficiently and new processing capacity would be developed to utilize the material that has formerly been left in the woods or exported. Total derived demand is projected to be 204 MMBF in 2022 under this scenario.

> Alternatives 1 and 2 with projected total outputs of 49 MMBF and 151 MMBF, respectively, could not provide sufficient volume to meet this scenario.
>
> Alternatives 3, 4, 5, 6, and 7 could provide sufficient volume to meet this scenario.

Scenario 4 – High Integrated Industry. This scenario builds on Scenario 3 and provides an estimate of the upper market level for the foreseeable future. In order for this situation to be realized, new investments in processing capacity would need to be made and additional market shares established. Total derived demand is projected to be 342 MMBF in 2022 under this scenario.

> Alternatives 1, 2, 3, 5 and 6 with projected total outputs of 49 MMBF, 151 MMBF, 205 MMBF, 267 MMBF, and 267 MMBF respectively, could not provide sufficient volume to meet this scenario.
>
> Alternatives 4 and 7 could provide sufficient volume to meet this scenario.

The ability of the seven alternatives to supply enough timber to satisfy the projected demand for timber under each scenario is summarized in Table S-1.

Current Production Levels, Installed Capacity, and Minimum Volumes Required by Various Processing Facilities. The existing mills in Southeast Alaska had an estimated active installed processing capacity of 261 MMBF in 2006 and a total processing capacity of 361 MMBF. The estimated NIC I components of the harvest volumes projected under each alternative range from 9 percent of the active installed processing capacity under Alternative 1 to 71 percent under Alternative 7. The NIC I volume projected under Alternative 5 (No Action) represents about 46 percent of the existing active processing capacity. The projected NIC I components represent smaller shares of the total installed capacity, ranging from 7 percent under Alternative 1 to 51 percent under Alternative 7.

Two of the future demand scenarios evaluated by Brackley et al. (2006a) involve an integrated industry. These scenarios are based on the assumption that as stable volumes get higher, the industry will develop in an integrated fashion, with operations and production that utilize materials that are inefficient or excess to one another's production. The potential components of an integrated industry could include sawmills, a veneer plant, and a medium density fiberboard (MDF) or bioenergy facility, among others. The different facilities would process different types of log. Sawmills would generally process higher quality material (high grade sawlogs), with the other types of facility processing lower quality material (low grade sawlogs and utility logs).

Based on the projected harvest volumes, only Alternatives 4 and 7 would provide sufficient volume to support an integrated industry that consisted of the existing sawmills, a veneer plant, and an MDF or Bioenergy facility. Under Alternative 5 (No Action), there would be sufficient volume to support the existing sawmills. There would also be sufficient volume to support one or more veneer plants or an MDF or other chip-related operation, but not both.

A number of timber projections were reviewed as part of this analysis. Based on this review, the Forest Service identified a potential upper planning cycle demand of

360 MMBF from all sources. Only Alternative 7 includes sufficient volume to meet this level of demand only from NFS acres.

Direct Employment and Income. Direct sawmill and logging employment estimates are presented in job-years, which represent the equivalent of one year's employment. This potential employment would not necessarily occur all in one year and estimated job totals do not directly translate into estimated numbers of affected workers. These estimates assume a linear relationship between harvest and employment levels, with a one percent change in harvest resulting in a one percent change in employment. In reality, changes in volume will have a lagged response in employment, but the assumed linear relationship is an approximation that can be used to compare alternatives.

Based on projected harvest volumes, average annual direct wood products employment would range from 494 annualized jobs under Alternative 1 to 1,922 jobs under Alternative 7. Approximately 274 of these annualized jobs would be associated with non-Tongass harvest under each alternative. Viewed in relation to Alternative 5 (No Action), projected direct employment would range from a 63 percent decrease under Alternative 1 to an increase of approximately 43 percent under Alternative 7.

Projected annual direct income, which is calculated based on the projected number of jobs, would range from $19.5 million under Alternative 1 to $72.5 million under Alternative 7. These totals also include income that would be generated by non-Tongass harvest.

Short-Term Effects

The following discussion provides an indication of potential short-term effects. Actual effects would depend on the volumes in each pool when the decision is implemented. In the case of the volume under contract, potential impacts would also depend on whether potentially affected sales were cancelled or exempted as part of the decision.

Volume under Contract. Alternative 1 would maintain the majority of the Inventoried Roadless Areas on the Tongass in a natural condition and would not allow timber harvest in those areas. Alternative 1 would affect 52 percent (54 MMBF) of the volume under contract as of August 2006 (104 MMBF). The volume currently under contract would not be affected by any of the other alternatives.

NEPA-Cleared Volume. Alternative 1 would affect 56 percent (255 MMBF) of the current NEPA-cleared volume as of August 2006 (454 MMBF). It should be noted that not all this volume is considered economic under current market conditions. Alternative 2 would affect 44 percent or 198 MMBF of this volume, which represents the volume that has passed through the NEPA process and is scheduled to be available for sale in the near future. None of the other alternatives would affect this volume.

Timber Volume in Preparation. Alternative 1 would affect 56 percent (298 MMBF) of the timber volume in preparation as of September 2006 (536 MMBF). Alternatives 2 and 3 would each affect approximately 7 percent or 40 MMBF of this volume. Alternatives 4, 5, 6, and 7 would not affect this volume.

Key Issue 3 – Protection of the wildlife habitat and biodiversity of the Tongass National Forest is of local and national significance and is affected by road development and timber harvest activities.

The Tongass National Forest supports a unique and important assemblage of wildlife including the largest population of brown bears and breeding bald eagles in the world, species of high importance for subsistence (e.g., Sitka black-tailed deer), an extensive array of endemic mammals and other species, and a large number of species that are at least partially dependent on old-growth habitats (e.g., marten and goshawk). Populations of many of these species and the biodiversity of Southeast Alaska are affected by timber harvest and the development of roads.

Old-Growth Harvest

The amount of harvest of POG is a key indicator of effects on many species, including goshawks, marten, endemic mammals, and deer (to some degree). The range of old-growth harvest is broad among the alternatives. Alternative 1 has the lowest maximum harvest of POG at 86,000 acres, while Alternative 7 has the highest maximum at 807,000 acres. After 100 years or so, a minimum of 90 percent of all POG on NFS lands would remain under Alternative 1 and 77 percent would remain under Alternative 7. Percentages for all of Southeast Alaska, including non-NFS lands, would be 82 percent for Alternative 1 and 71 percent for Alternative 7. The other five alternatives would rank between Alternatives 1 and 7; their order from lowest to highest harvest would have Alternative 2 at the low end progressing to Alternative 3, then 6, then 5, and then 4.

Road Development

The Tongass currently has 4,941 miles of existing roads (including closed and non-system roads). This total includes 2,619 miles of open roads, plus 913 miles of closed roads that are in storage and 1,409 miles of non-system roads. Road construction can negatively affect wildlife by eliminating habitats and by permitting increased access, which can result in increased harvests and human-large predator interactions.

Under Alternative 1, an estimated maximum of 774 new road miles would be developed over 100 years. For Alternatives 2 and 3 the estimated maximum new road construction would be 2,079 and 2,799 miles, respectively. The majority of these road miles would be closed after harvest activities are completed, and reopened at the next entry. The maximum road miles to be constructed under Alternatives 5 and 6 would be 3,874 and 3,744, respectively. Alternative 4 would construct a maximum of 4,890 miles of new road and Alternative 7 would construct a maximum of 5,825 miles of new road.

A better indicator of road effects on wildlife is the road density within Wildlife Analysis Areas (WAA). On Tongass NFS lands, 8 percent of the WAAs that make up the Tongass have a road density greater than 1.0 mile per square mile under existing conditions. Road density would increase in many areas after full implementation of the alternatives. Under Alternative 1, the density would increase so that a maximum of 11 percent of the WAAs would have a density greater than 1.0 mile per square mile. Alternatives 2, 3, and 6 would have a maximum of 16 tp 18 percent, Alternative 5 would have a maximum of 19 percent, and Alternatives 4 and 7 would have 23 to 25 percent. These percentages would increase further when cumulative road development, including future road development on non-NFS lands, is considered. The percentage of WAAs with road density on all lands (including non-NFS lands) greater than 1.0 mile per square mile would be 20 percent for

Alternative 1, 23 to 26 percent for Alternatives 2, 3, 5, and 6, and 28 to 31 percent for Alternatives 4 and 7.

Representation of Old-Growth Forests

The percentage of POG remaining in each biogeographic province and in each ecological subsection is an indication of the degree to which all potentially valuable ecological communities remain fully represented.

After 100 years of Alternative 1 implementation, 19 of the 23 biogeographic provinces covering Southeast Alaska would have 75 percent or more of their POG remaining and none would have less than 50 percent (minimum value = 55 percent). For large-tree POG, 16 out of 23 provinces would have at least 50 percent of the original amount remaining (minimum value = 32%).

At the other end of the spectrum, after 100 years of implementation of Alternatives 4 or 7, 11 to 12 of the 23 biogeographic provinces would have 75 percent or more of their POG remaining and one would have less than 50 percent (minimum value = 44 percent for Alternative 7). Considering large-tree POG, 13 to 14 of the provinces would have at least 50 percent of the original amount remaining (minimum value = 29 percent under Alternative 7).

The other four alternatives (Alternatives 2, 3, 5, and 6) would all have values within these ranges; they would have 13 to 18 of the 23 biogeographic provinces covering Southeast Alaska with 75 percent or more of their POG remaining. None of these alternatives would have any biogeographic provinces with less than 50 percent of their POG. Each of them would also have 16 out of 23 provinces with least 50 percent of the original large-tree POG remaining (minimum value = 31%).

Conservation Strategy and Landscape Connectivity

An adequate amount and distribution of high quality old-growth blocks with good landscape connectivity is fundamental to the “coarse filter” aspect of the Old-Growth Forest Conservation Strategy and is important for the maintenance of viable, well-distributed populations of many species of wildlife. Because of the spacing of old-growth reserves and other non-development LUDs, Alternatives 1 and 2 would result in a good to excellent distribution of high quality old-growth blocks over the long term, and would have little to no effects on landscape “pinch-points.” Alternatives 3, 5, and 6 would have good to very good spacing of old-growth reserves and other non-development LUDs and would similarly effect only one “pinch-point.”

Under Alternative 4, the long-term result would be a good distribution of high quality old-growth blocks in the four biogeographic provinces with old-growth reserves, but a poor to fair distribution in the other provinces over the long term. The old-growth retention requirement would mitigate this to some degree, but would not necessarily result in blocks or large patches of POG being retained. This alternative would also negatively affect three critical landscape “pinch-points.”

Alternative 7 would result in a poor distribution of high quality old-growth blocks over the long term throughout most of the Tongass because of the lack of old-growth reserves, the lack of an old-growth retention requirement, and the high acreage of development LUDs. It would negatively affect four critical landscape “pinch-points” and result in a lower degree of landscape connectivity due to narrower beach buffers.

Species-Specific Effects

Expert panel viability assessments were conducted for key species to rate the alternatives considered in the 1997 Forest Plan Revision EIS. These ratings were transferred to the alternatives in this EIS, based on the four alternatives that are similar between EISs (i.e., 1997-Alternative 6 is similar to 2007-Alternative 4, 1997-Alternative 11 is similar to 2007-Alternatives 5 and 6, and 1997-Alternative 2 is similar to 2007-Alternative 7), and based on harvest acreage similarities. The ratings were also transferred into a relative qualitative description of the likelihood of maintaining viable, well-distributed populations so that the alternatives could more easily be compared.

Under Alternative 1, the likelihood of maintaining viable, well-distributed populations on the Tongass after 100 years is estimated to be very high for the goshawk, marten, wolf, and brown bear, and moderate for endemic mammals. Alternative 2 would rate almost as high. Under Alternative 3, this likelihood is estimated to be very high for the goshawk; high for the marten, wolf, and brown bear; and moderate for endemic mammals.

Alternatives 5 and 6 would have similar ratings. The likelihood of maintaining viable, well-distributed populations on the Tongass after 100 years is estimated to be high for the goshawk, wolf and brown bear; and moderate for the marten and endemic mammals.

Alternatives 4 and 7 rate the lowest among the alternatives. For Alternative 4, the likelihood of maintaining viable, well distributed populations on the Tongass after 100 years is estimated to be high for the wolf; moderately high for the goshawk and brown bear; moderate for the marten; and moderately low for endemic mammals. For Alternative 7, the likelihood is estimated to be moderately high for the wolf and brown bear; moderate for the goshawk and marten; and very low for endemic mammals.

Deer habitat capability expressed in terms of percent of 1954 values can be used to identify the amount of habitat change over time (current habitat capability = 88 percent of 1954 value, based on the deer model). After 100 years of Forest Plan implementation, the percentage for Alternative 1 could drop as low as 86 percent, 84 percent under Alternative 2, 83 percent under Alternative 3, 82 percent under Alternative 6, 81 percent under Alternative 5, 79 percent under Alternative 4, and 77 percent under Alternative 7. These percentages could be increased somewhat with more intensive management of young-growth forests.

This page is intentionally left blank.

Table 2-20
Summary of Effects Matrix

Value/Resource	Alternative 1	Alternative 2	Alternative 3	Alternative 4	Alternative 5	Alternative 6	Alternative 7
PHYSICAL AND BIOLOGICAL ENVIRONMENT							
Karst							
Karst Resources: Forest Plan S&Gs fully protect high vulnerability karst lands and other karst areas also have S&Gs for protection. However, some effects may occur as a result of timber harvest and road construction. The relative effects on karst resources are proportional to the amount of karst lands in the mapped suitable forest land base.	Maximum harvest after 100+ years on karst lands is 12,000 acres of old growth and 17,000 acres of young growth. Implementation of S&Gs and site-specific mitigation measures will mitigate potential effects.	Maximum harvest after 100+ years on karst lands is 18,000 acres of old growth and 43,000 acres of young growth. Implementation of S&Gs and site-specific mitigation measures will mitigate potential effects.	Maximum harvest after 100+ years on karst lands is 20,000 acres of old growth and 46,000 acres of young growth. Implementation of S&Gs and site-specific mitigation measures will mitigate potential effects.	Maximum harvest after 100+ years on karst lands is 33,000 acres of old growth and 53,000 acres of young growth. Implementation of S&Gs and site-specific mitigation measures will mitigate potential effects.	Maximum harvest after 100+ years on karst lands is 25,000 acres of old growth and 52,000 acres of young growth. Implementation of S&Gs and site-specific mitigation measures will mitigate potential effects.	Maximum harvest after 100+ years on karst lands is 23,000 acres of old growth and 50,000 acres of young growth. Implementation of S&Gs and site-specific mitigation measures will mitigate potential effects.	Maximum harvest after 100+ years on karst lands is 44,000 acres of old growth and 59,000 acres of young growth. Implementation of S&Gs and site-specific mitigation measures will mitigate potential effects.
Soils							
Soil Productivity, Erosion, and Mass Wasting: Changes in soil productivity are proportional to the extent of road development, with road development removing land from productive status. Soil erosion and mass wasting potential is also proportional to the extent of road development, as well as the amount of harvest on steep slopes.	Cumulative acres covered by road surfaces on NFS lands are estimated to increase by a maximum of 2,300 after 100 yrs. Amount of additional harvest on slopes ≥ 67% would be a maximum of 2,400 acres after 100 yrs.	Cumulative acres covered by road surfaces on NFS lands are estimated to increase by a maximum of 6,200 after 100 yrs. Amount of additional harvest on slopes ≥ 67% would be a maximum of 8,200 acres after 100 yrs.	Cumulative acres covered by road surfaces on NFS lands are estimated to increase by a maximum of 8,400 after 100 yrs. Amount of additional harvest on slopes ≥ 67% would be a maximum of 12,400 acres after 100 yrs.	Cumulative acres covered by road surfaces on NFS lands are estimated to increase by a maximum of 14,700 after 100 yrs. Amount of additional harvest on slopes ≥ 67% would be a maximum of 21,600 acres after 100 yrs.	Cumulative acres covered by road surfaces on NFS lands are estimated to increase by a maximum of 11,600 after 100 yrs. Amount of additional harvest on slopes ≥ 67% would be a maximum of 17,400 acres after 100 yrs.	Cumulative acres covered by road surfaces on NFS lands are estimated to increase by a maximum of 11,200 after 100 yrs. Amount of additional harvest on slopes ≥ 67% would be a maximum of 16,600 acres after 100 yrs.	Cumulative acres covered by road surfaces on NFS lands are estimated to increase by a maximum of 17,500 after 100 yrs. Amount of additional harvest on slopes ≥ 67% would be a maximum of 30,000 acres after 100 yrs.
Water and Wetlands							
Stream Flows: Effects on stream flows are expected to vary by watershed and are difficult to predict, but are expected to be small. Any effects that do occur are expected to be proportional to the extent of road development and harvest.	See cumulative acres covered by road surfaces under Soils, road development under Fish, and old-growth forest harvest under Biodiversity and Plants.	See cumulative acres covered by road surfaces under Soils, road development under Fish, and old-growth forest harvest under Biodiversity and Plants. Public Water Supplies: The supply and quality of water produced by municipal watersheds.	No change in municipal watershed LUD.	No change in municipal watershed LUD.	No change in municipal watershed LUD.	No change in municipal watershed LUD.	No change in municipal watershed LUD.	No change in municipal watershed LUD.	No change in municipal watershed LUD.
Fish							
Fish Passage: Effects of road-stream crossings on fish passage are proportional to the length of roads constructed. However, Forest Plan S&Gs and monitoring are expected to reduce this impact to low levels for all alternatives over the long term.	Cumulative road development on NFS lands is expected to increase by a maximum of 774 miles after 100 yrs. This represents a 16% increase over existing conditions.	Cumulative road development on NFS lands is expected to increase by a maximum of 2,079 miles after 100 yrs. This represents a 42% increase over existing conditions.	Cumulative road development on NFS lands is expected to increase by a maximum of 2,799 miles after 100 yrs. This represents a 57% increase over existing conditions.	Cumulative road development on NFS lands is expected to increase by a maximum of 4,890 miles after 100 yrs. This represents a 99% increase over existing conditions.	Cumulative road development on NFS lands is expected to increase by a maximum of 3,874 miles after 100 yrs. This represents a 78% increase over existing conditions.	Cumulative road development on NFS lands is expected to increase by a maximum of 3,744 miles after 100 yrs. This represents a 76% increase over existing conditions.	Cumulative road development on NFS lands is expected to increase by a maximum of 5,825 miles after 100 yrs. This represents a 118% increase over existing conditions.
Fish Habitat: Effects on fish habitat can be measured by the amount of road development, road density, and timber harvest activity. However, Forest Plan S&Gs associated with riparian areas, wetlands, beach and estuary fringe, etc., are expected to reduce these effects to nonsignificant levels.	After 100 yrs, average road density would be a maximum of 0.22 mi/sq mi with 96% of VCUs having a density < 2 mi/sq mi. on NFS lands. Cumulative average road density on NFS and non-NFS lands combined would be a maximum of 0.42 mi/sq mi with 90% of VCUs having a density < 2 mi/sq mi. Also see road development under Fish Passage and harvest acres under Biodiversity.	After 100 yrs, average road density would be a maximum of 0.27 mi/sq mi with 94% of VCUs having a density < 2 mi/sq mi. on NFS lands. Cumulative average road density on NFS and non-NFS lands combined would be a maximum of 0.47 mi/sq mi with 88% of VCUs having a density < 2 mi/sq mi. Also see road development under Fish Passage and harvest acres under Biodiversity.	After 100 yrs, average road density would be a maximum of 0.30 mi/sq mi with 93% of VCUs having a density < 2 mi/sq mi. on NFS lands. Cumulative average road density on NFS and non-NFS lands combined would be a maximum of 0.49 mi/sq mi with 88% of VCUs having a density < 2 mi/sq mi. Also see road development under Fish Passage and harvest acres under Biodiversity.	After 100 yrs, average road density would be a maximum of 0.38 mi/sq mi with 92% of VCUs having a density < 2 mi/sq mi. on NFS lands. Cumulative average road density on NFS and non-NFS lands combined would be a maximum of 0.57 mi/sq mi with 86% of VCUs having a density < 2 mi/sq mi. Also see road development under Fish Passage and harvest acres under Biodiversity.	After 100 yrs, average road density would be a maximum of 0.34 mi/sq mi with 92% of VCUs having a density < 2 mi/sq mi. on NFS lands. Cumulative average road density on NFS and non-NFS lands combined would be a maximum of 0.53 mi/sq mi with 87% of VCUs having a density < 2 mi/sq mi. Also see road development under Fish Passage and harvest acres under Biodiversity.	After 100 yrs, average road density would be a maximum of 0.33 mi/sq mi with 93% of VCUs having a density < 2 mi/sq mi. on NFS lands. Cumulative average road density on NFS and non-NFS lands combined would be a maximum of 0.52 mi/sq mi with 87% of VCUs having a density < 2 mi/sq mi. Also see road development under Fish Passage and harvest acres under Biodiversity.	After 100 yrs, average road density would be a maximum of 0.41 mi/sq mi with 90% of VCUs having a density < 2 mi/sq mi. on NFS lands. Cumulative average road density on NFS and non-NFS lands combined would be a maximum of 0.60 mi/sq mi with 84% of VCUs having a density < 2 mi/sq mi. Also see road development under Fish Passage and harvest acres under Biodiversity.
Biodiversity and Plants							
Old-Growth Forest Harvest: Because of the importance of old-growth forests to the biodiversity of Southeast Alaska and because it is the habitat that is affected the most on both NFS and non-NFS lands, a measure of effects on biodiversity and plants is the maximum amount of productive old growth (POG) harvest.	A maximum of 86,000 acres of POG would be harvested on NFS lands after 100 yrs. Assuming all of these acres were harvested, approximately 90% of original POG on NFS lands and 82% of original POG on all lands in SE Alaska would remain (past and future harvest on non-NFS lands is included).	A maximum of 215,000 acres of POG would be harvested on NFS lands after 100 yrs. Assuming all of these acres were harvested, approximately 88% of original POG on NFS lands and 80% of original POG on all lands in SE Alaska would remain (past and future harvest on non-NFS lands is included).	A maximum of 313,000 acres of POG would be harvested on NFS lands after 100 yrs. Assuming all of these acres were harvested, approximately 86% of original POG on NFS lands and 78% of original POG on all lands in SE Alaska would remain (past and future harvest on non-NFS lands is included).	A maximum of 656,000 acres of POG would be harvested on NFS lands after 100 yrs. Assuming all of these acres were harvested, approximately 79% of original POG on NFS lands and 73% of original POG on all lands in SE Alaska would remain (past and future harvest on non-NFS lands is included).	A maximum of 463,000 acres of POG would be harvested on NFS lands after 100 yrs. Assuming all of these acres were harvested, approximately 83% of original POG on NFS lands and 76% of original POG on all lands in SE Alaska would remain (past and future harvest on non-NFS lands is included).	A maximum of 445,000 acres of POG would be harvested on NFS lands after 100 yrs. Assuming all of these acres were harvested, approximately 83% of original POG on NFS lands and 76% of original POG on all lands in SE Alaska would remain (past and future harvest on non-NFS lands is included).	A maximum of 807,000 acres of POG would be harvested on NFS lands after 100 yrs. Assuming all of these acres were harvested, approximately 77% of original POG on NFS lands and 71% of original POG on all lands in SE Alaska would remain (past and future harvest on non-NFS lands is included).
Old-Growth Distribution and Representation: The percentage of POG and large-tree POG remaining in each biogeographic province for all of Southeast Alaska (including non-NFS lands) is an indication of the degree to which all potentially valuable ecological communities remain fully represented.	After 100 yrs, 19 of the 23 biogeographic provinces would have 75% or more of their POG remaining and none would have less than 50% (minimum value = 55%). For large-tree POG, 16 of the 23 would have at least 50% remaining and none would have less than 30% (minimum value = 32%).	After 100 yrs, 18 of the 23 biogeographic provinces would have 75% or more of their POG remaining and none would have less than 50% (minimum value = 54%). For large-tree POG, 16 of the 23 would have at least 50% remaining and none would have less than 30% (minimum value = 32%).	After 100 yrs, 16 of the 23 biogeographic provinces would have 75% or more of their POG remaining and none would have less than 50% (minimum value = 52%). For large-tree POG, 16 of the 23 would have at least 50% remaining and none would have less than 30% (minimum value = 32%).	After 100 yrs, 12 of the 23 biogeographic provinces would have 75% or more of their POG remaining and 1 would have less than 50% (minimum value = 49%). For large-tree POG, 14 of the 23 would have at least 50% remaining and none would have less than 30% (minimum value = 31%).	After 100 yrs, 13 of the 23 biogeographic provinces would have 75% or more of their POG remaining and none would have less than 50% (minimum value = 51%). For large-tree POG, 16 of the 23 would have at least 50% remaining and none would have less than 30% (minimum value = 31%).	After 100 yrs, 13 of the 23 biogeographic provinces would have 75% or more of their POG remaining and none would have less than 50% (minimum value = 51%). For large-tree POG, 16 of the 23 would have at least 50% remaining and none would have less than 30% (minimum value = 31%).	After 100 yrs, 11 of the 23 biogeographic provinces would have 75% or more of their POG remaining and 1 would have less than 50% (minimum value = 44%). For large-tree POG, 13 of the 23 would have at least 50% remaining and 1 would have less than 30% (minimum value = 29%).
Wildlife							
Conservation Strategy and Landscape Connectivity: An adequate amount and distribution of high quality old-growth blocks with good landscape connectivity is fundamental to the "coarse filter" aspect of the Old-Growth Forest Conservation Strategy and is important for the maintenance of viable, well-distributed populations of many species of wildlife	This alternative would result in a good to excellent distribution of high quality old-growth blocks over the long term, and would not have a major effect on landscape "pinch-points." In addition to more non-development LUDs, it would improve the protection of high quality old growth due to refinements in small old-growth reserve boundaries, relative to Alternative 5.	This alternative would result in a good to excellent distribution of high quality old-growth blocks over the long term, and would have some effect on one critical landscape "pinch-point." In addition to more non-development LUDs, it would improve the protection of high quality old growth due to refinements in small old-growth reserve boundaries, relative to Alternative 5.	This alternative would result in a good to very good distribution of high quality old-growth blocks over the long term, and would have some effect on one critical landscape "pinch-point." In addition to more non-development LUDs, it would improve the protection of high quality old growth due to refinements in small old-growth reserve boundaries, relative to Alternative 5.	This alternative would result in a good distribution of high quality old-growth blocks in the four biogeographic provinces with old-growth reserves, but a poor to fair distribution in the other provinces over the long term. It would negatively affect three critical landscape "pinch-points."	This alternative would result in a good to very good distribution of high quality old-growth blocks over the long term, and would have some effect on one critical landscape "pinch-point" on Prince of Wales Island.	This alternative would result in a good to very good distribution of high quality old-growth blocks over the long term, with improvements over Alternative 5 due to refinements in the small old-growth reserve boundaries. It would have some effect on one critical landscape "pinch-point" on Prince of Wales Island.	This alternative would result in a poor distribution of high quality old-growth blocks over the long term because of the lack of old-growth reserves, the lack of an old-growth retention requirement, and the high acreage of development LUDs. It would negatively affect 4 critical landscape "pinch-points" and result in a lower degree of landscape connectivity due to narrower beach buffers.
Key Species Distribution and Viability: Expert panel viability assessments were made for key species to rate the alternatives considered in the 1997 Forest Plan Revision EIS. These ratings can be transferred to the alternatives in this EIS, based on the four alternatives that are similar between EISs and harvest acreage similarities.	The likelihood of maintaining viable, well distributed populations on the Tongass after 100 years is estimated to be very high for the goshawk, marten, wolf, and brown bear, and moderate for endemic mammals.	The likelihood of maintaining viable, well distributed populations on the Tongass after 100 years is estimated to be very high for the goshawk and wolf; high for the marten and brown bear; and moderate for endemic mammals.	The likelihood of maintaining viable, well distributed populations on the Tongass after 100 years is estimated to be very high for the goshawk; high for the marten, wolf, and brown bear; and moderate for endemic mammals.	The likelihood of maintaining viable, well distributed populations on the Tongass after 100 years is estimated to be high for the wolf; moderately high for the goshawk and brown bear; moderate for the marten; and moderately low for endemic mammals.	The likelihood of maintaining viable, well distributed populations on the Tongass after 100 years is estimated to be high for the goshawk, wolf, and brown bear; and moderate for the marten and endemic mammals.	The likelihood of maintaining viable, well distributed populations on the Tongass after 100 years is estimated to be high for the goshawk, wolf, and brown bear; and moderate for the marten and endemic mammals.	The likelihood of maintaining viable, well distributed populations on the Tongass after 100 years is estimated to be moderately high for the wolf and brown bear; moderate for the goshawk and marten; and very low for endemic mammals.
Deer Habitat: Deer habitat capability expressed in terms of percent of 1954 values can be used to identify the amount of habitat change over time (current habitat capability = 88% of 1954 value, based on the deer model).	After 100 years, deer habitat capability would be a minimum of 86% of 1954 value on NFS lands. This value has the potential to be increased with young-growth management.	After 100 years, deer habitat capability would be a minimum of 84% of 1954 value on NFS lands. This value has the potential to be increased with young-growth management.	After 100 years, deer habitat capability would be a minimum of 83% of 1954 value on NFS lands. This value has the potential to be increased with young-growth management.	After 100 years, deer habitat capability would be a minimum of 79% of 1954 value on NFS lands. This value has the potential to be increased with young-growth management.	After 100 years, deer habitat capability would be a minimum of 81% of 1954 value on NFS lands. This value has the potential to be increased with young-growth management.	After 100 years, deer habitat capability would be a minimum of 82% of 1954 value on NFS lands. This value has the potential to be increased with young-growth management.	After 100 years, deer habitat capability would be a minimum of 77% of 1954 value on NFS lands. This value has the potential to be increased with young-growth management.

Summary of Effects Matrix

Value/Resource	Alternative 1	Alternative 2	Alternative 3	Alternative 4	Alternative 5	Alternative 6	Alternative 7
				HUMAN USES AND LAND MANAGEMENT			
Lands and Other Special Land Use Designations							
Lands: No significant environmental consequences from NFS land ownership administration activities under any alternatives. No land ownership adjustments are proposed under any alternatives. Potential changes to areas designated as Experimental Forest and Special Interest Area. No changes to Research Natural Areas; Wild, Scenic, or Recreational Rivers; or Municipal Watershed LUDs.	Forest Service would conduct land administration under the proposed Forest-wide standards and guidelines, which reflect minimal changes from the current (1997) Forest Plan. Recommended replacement of Young Bay Experimental Forest. Proposed designation of 23 new Special Interest Areas, with net increase of 47,000 acres.	Forest Service would conduct land administration under the proposed Forest-wide standards and guidelines, which reflect minimal changes from the current (1997) Forest Plan. Recommended replacement of Young Bay Experimental Forest. Proposed designation of 23 new Special Interest Areas, with net increase of 47,000 acres.	Forest Service would conduct land administration under the proposed Forest-wide standards and guidelines, which reflect minimal changes from the current (1997) Forest Plan. Forest Service would conduct land administration under the proposed Forest-wide standards and guidelines, which reflect minimal changes from the current (1997) Forest Plan. Recommended replacement of Young Bay Experimental Forest. Proposed designation of 23 new Special Interest Areas, with net increase of 47,000 acres.	Lands would continue to be managed in accordance with the 1997 Forest Plan standards and guidelines under this alternative.	Forest Service would conduct land administration under the proposed Forest-wide standards and guidelines, which reflect minimal changes from the current (1997) Forest Plan. Recommended replacement of Young Bay Experimental Forest. Proposed designation of 23 new Special Interest Areas, with net increase of 47,000 acres.	Forest Service would conduct land administration under the proposed Forest-wide standards and guidelines, which reflect minimal changes from the current (1997) Forest Plan. Recommended replacement of Young Bay Experimental Forest. Proposed designation of 23 new Special Interest Areas, with net increase of 47,000 acres.
Transportation and Utilities							
National Forest Transportation System Roads: The level of projected timber harvest would affect the road system needed to manage the timber land base.	A maximum of 774 miles would be constructed over 100 yrs, resulting in a cumulative total of 5,716 total miles of open and closed roads at the end of this period.	A maximum of 2,079 miles would be constructed over 100 yrs, resulting in a cumulative total of 7,021 total miles of open and closed roads at the end of this period.	A maximum of 2,799 miles would be constructed over 100 yrs, resulting in a cumulative total of 7,741 total miles of open and closed roads at the end of this period.	A maximum of 4,890 miles would be constructed over 100 yrs, resulting in a cumulative total of 9,832 total miles of open and closed roads at the end of this period.	A maximum of 3,874 miles would be constructed over 100 yrs, resulting in a cumulative total of 8,816 total miles of open and closed roads at the end of this period.	A maximum of 3,744 miles would be constructed over 100 yrs, resulting in a cumulative total of 8,686 total miles of open and closed roads at the end of this period.	A maximum of 5,825 miles would be constructed over 100 yrs, resulting in a cumulative total of 10,767 total miles of open and closed roads at the end of this period.
Southeast Alaska Transportation Plan (SATP): The Forest Service signed a Memorandum of Understanding (MOU) with the State of Alaska in 2006 to provide rights-of-way for the road corridors covered by Public Law 109-59. The MOU also grants easements to the Forest Service for marine access points and LTFs listed on Map 92337.	There would be no effect on the SATP under this alternative.	There would be no effect on the SATP under this alternative.	There would be no effect on the SATP under this alternative.	There would be no effect on the SATP under this alternative.	There would be no effect on the SATP under this alternative.	There would be no effect on the SATP under this alternative.	There would be no effect on the SATP under this alternative.
Timber							
Suitable Forest Lands: Forest lands which are biologically capable of producing commercial wood products without irreversibly harming resources, have a reasonable assurance of adequate reforestation, and for which there is management direction that timber production is appropriate.	312,000 acres are estimated to be suitable; 144,000 acres of these are scheduled suitable lands.	545,000 acres are estimated to be suitable; 394,000 acres of these are scheduled suitable lands.	661,000 acres are estimated to be suitable; 514,000 acres of these are scheduled suitable lands.	999,000 acres are estimated to be suitable; 892,000 acres of these are scheduled suitable lands.	781,000 acres are estimated to be suitable; 687,000 acres of these are scheduled suitable lands.	774,000 acres are estimated to be suitable; 663,000 acres of these are scheduled suitable lands.	1,174,000 acres are estimated to be suitable; 1,070,000 acres of these are scheduled suitable lands.
Allowable Sale Quantity (ASQ): The ASQ is the maximum quantity of timber that may be scheduled from Suitable Forest lands for a 10-year period expressed as an annual average.	The ASQ for the 1st decade and after would be slightly over 49 MMBF.	The ASQ for the 1st decade and after would be 152 MMBF.	The ASQ for the 1st decade would be 185 MMBF. The ASQ for the 2nd decade and after would be 203 MMBF.	The ASQ for the 1st decade would be 312 MMBF. The ASQ for the 2nd decade and after would be 342 MMBF.	The ASQ for the next decade and after would be 267 MMBF.	The ASQ for the next decade and after would be 267 MMBF.	The ASQ for the next decade and after would be 421 MMBF.
Non-Interchangeable Component (NIC)I: NIC I is the portion of the ASQ that may be harvested using existing logging systems.	NIC I for the 1st and 2nd decades is estimated to be slightly less than 49 MMBF.	NIC I for the 1st and 2nd decades is estimated to be 144 MMBF.	NIC I for the 1st and 2nd decades is estimated to be 168 and 186 MMBF, respectively.	NIC I for the 1st and 2nd decades is estimated to be 270 and 294 MMBF, respectively.	NIC I for the 1st and 2nd decades is estimated to be 240 and 242 MMBF, respectively.	NIC I for the 1st and 2nd decades is estimated to be 237 and 236 MMBF, respectively.	NIC I for the 1st and 2nd decades is estimated to be 365 and 370 MMBF, respectively.
Existing Timber Volume Under Contract: Changing suitable land to non-development LUDs could affect timber sales that have been sold.	There is potential for a high effect on timber volume under contract; but this is dependent on the decision.	There would be no effect on the volume under contract under this alternative.	There would be no effect on the volume under contract under this alternative.	There would be no effect on the volume under contract under this alternative.	There would be no effect on the volume under contract under this alternative.	There would be no effect on the volume under contract under this alternative.	There would be no effect on the volume under contract under this alternative.
Minerals							
Mineral Resources: No modification of Forest Service management of mineral activities specific to any alternative. No change in acreage withdrawn from mineral entry, or lands assigned to Minerals LUD. Distribution of other LUD assignments by alternative could affect costs of mineral exploration, development, production or reclamation activities, which could influence level of future mineral activity,	**Identified Mineral Tracts:**	**Identified Mineral Tracts:**	**Identified Mineral Tracts:**	**Identified Mineral Tracts:**	**Identified Mineral Tracts:**	**Identified Mineral Tracts:**	**Identified Mineral Tracts:**

Scenery							
Scenic Integrity Objectives (SIOs): SIOs define the degree to which the natural landscape can be altered. Visual priority routes and use areas were used to identify seen and seldom seen areas and to map the appropriate SIO.	Visual priority routes and use areas would be protected. Approximately 62% of the Forest would be managed under the High SIO and 4% under Low and Very Low.	Visual priority routes and use areas would be protected. Approximately 62% of the Forest would be managed under the High SIO and 9% under Low and Very Low.	Visual priority routes and use areas would be protected. Approximately 61% of the Forest would be managed under the High SIO and 14% under the Low and Very Low.	Visual priority routes and use areas would be protected. Approximately 56% of the Forest would be managed under the High SIO and 23% under Low and Very Low.	Visual priority routes and use areas would be protected. Approximately 61% of the Forest would be managed under the High SIO and 18% under Low and Very Low.	Visual priority routes and use areas would be protected. Approximately 60% of the Forest would be managed under the High SIO and 17% under Low and Very Low.	Visual priority routes and use areas would be protected. Approximately 54% of the Forest would be managed under the High SIO and 25% under Low and Very Low.

Table 2-20 (continued)
Summary of Effects Matrix

Value/Resource	Alternative 1	Alternative 2	Alternative 3	Alternative 4	Alternative 5	Alternative 6	Alternative 7
Subsistence							
Abundance and Distribution: The majority of subsistence resources (fish and marine invertebrates) would not be affected. However, analysis suggests that deer habitat capabilities in portions of the Tongass may not be adequate to sustain current/future harvest levels under any of the alternatives. The possibility of a significant restriction in harvest resulting from changes in abundance and distribution is assessed in relation to Alternative 5 (No Action).	The possibility of a significant restriction would be lower relative to Alternative 5 (No Action) because of a 77% reduction in development LUD acreage under this alternative.	The possibility of a significant restriction would be lower relative to Alternative 5 (No Action) because of a 46% reduction in development LUD acreage under this alternative.	The possibility of a significant restriction would be slightly lower relative to Alternative 5 (No Action) because of a 22% reduction in development LUD acreage under this alternative.	The possibility of a significant restriction would be higher relative to Alternative 5 (No Action) because of a 31% increase in development LUD acreage under this alternative.	The possibility of a significant restriction, resulting from a change in abundance or distribution, would be the same under this alternative as under Alternative 11 in the 1997 Forest Plan FEIS.	The possibility of a significant restriction, resulting from a change in abundance or distribution, would be the same under this alternative as under Alternative 11 in the 1997 Forest Plan FEIS.	The possibility of a significant restriction would be higher relative to Alternative 5 (No Action) because of a 40% increase in development LUD acreage under this alternative.
Competition: The subsistence analysis concluded that there could be a significant possibility of a significant restriction of subsistence use through increased competition. The possibility of a significant restriction in harvest resulting from a change in competition is assessed in relation to Alternative 5 (No Action).	The possibility of a significant restriction, resulting from a change in competition, would be lower relative to Alternative 5 (No Action) because of a 80% reduction in proposed new road construction under this alternative.	The possibility of a significant restriction, resulting from a change in competition, would be lower relative to Alternative 5 (No Action) because of a 46% reduction in proposed new road construction under this alternative.	The possibility of a significant restriction, resulting from a change in competition, would be lower relative to Alternative 5 (No Action) because of a 28% reduction in proposed new road construction under this alternative.	The possibility of a significant restriction, resulting from a change in competition, would be higher relative to Alternative 5 (No Action) because of a 26% increase in proposed new road construction under this alternative.	The possibility of a significant restriction, resulting from a change in competition, would be the same under this alternative as under Alternative 11 in the 1997 Forest Plan FEIS.	The possibility of a significant restriction, resulting from a change in competition, would be slightly less under this alternative as under Alternative 11 in the 1997 Forest Plan FEIS.	The possibility of a significant restriction, resulting from a change in competition, would be higher relative to Alternative 5 (No Action) because of a 50% increase in proposed new road construction under this alternative.
Heritage Resources and Sacred Sites							
Heritage Resources and Sacred Sites: Potential for effects on these resources is proportional to the amount of harvest and road construction expected to occur. However, because of inventory and tribal consultation that is required, the risk of effects is relatively low.	See road development under Fish and old-growth forest harvest under Biodiversity and Plants as measures of the amount of disturbance. However, because of required inventory and tribal consultation, the risk of effects is relatively low.	See road development under Fish and old-growth forest harvest under Biodiversity and Plants as measures of the amount of disturbance. However, because of required inventory and tribal consultation, the risk of effects is relatively low.	See road development under Fish and old-growth forest harvest under Biodiversity and Plants as measures of the amount of disturbance. However, because of required inventory and tribal consultation, the risk of effects is relatively low.
Roadless Areas							
Roadless Areas: Roadless areas within moderate and intensive development LUDs would change from roadless to developed status over time.	No acres (0%) of existing roadless areas would be identified as suitable for harvest. The only acres in development LUDs would be Experimental Forests.	0.8 million acres (9%) of the existing roadless areas would be allocated to moderate and intensive development LUDs. Approximately 89,000 acres (0.9%) would be suitable and scheduled for harvest.	1.7 million acres (18%) of the existing roadless areas would be allocated to moderate and intensive development LUDs. Approximately 186,000 acres (2.0%) would be suitable and scheduled for harvest.	3.4 million acres (36%) of the existing roadless areas would be allocated to moderate and intensive development LUDs. Approximately 498,000 acres (5.2%) would be suitable and scheduled for harvest.	2.4 million acres (26%) of the existing roadless areas would be allocated to moderate and intensive development LUDs. Approximately 316,000 acres (3.3%) would be suitable for harvest.	2.3 million acres (24%) of the existing roadless areas would be allocated to moderate and intensive development LUDs. Approximately 307,000 acres (3.2%) would be suitable for harvest.	3.7 million acres (39%) of the existing roadless areas would be allocated to moderate and intensive development LUDs. Approximately 583,000 acres (6.1%) would be suitable for harvest.
Wilderness							
Wilderness: None of the alternatives involve recommending new areas for wilderness or LUD II designation. Roadless areas within the Tongass National Forest were evaluated for recommendations as potential wilderness in the 2003 Forest Plan SEIS (USDA Forest Service 2003).	Wilderness and LUD II areas would be managed under the updated and edited version of the current Forest Plan presented as the Proposed Land and Resource Management Plan.	Same as Alternative 1.	Same as Alternative 1.	Same as Alternative 1.	Wilderness and LUD II areas would be managed under the current Forest Plan.	Same as Alternative 1.	Same as Alternative 1.
ECONOMIC AND SOCIAL ENVIRONMENT							
Economic Impact Analysis							
Long-Term Wood Products Effects: Long-term employment projections are based on the NIC I Component of the ASQ and include a projected non-Tongass harvest of 109 MMBF, which is the same under all the alternatives. Projections are average annual equivalents for the next 10 years and assume full implementation. These totals do not include indirect or induced employment effects.	Projected average annual direct employment would be 365 logging jobs and 129 sawmill jobs under this alternative.	Projected average annual direct employment would be 583 logging jobs and 336 sawmill jobs under this alternative.	Projected average annual direct employment would be 680 logging jobs and 428 sawmill jobs under this alternative.	Projected average annual direct employment would be 880 logging jobs and 616 sawmill jobs under this alternative.	Projected average annual direct employment would be 803 logging jobs and 544 sawmill jobs under this alternative.	Projected average annual direct employment would be 801 logging jobs and 542 sawmill jobs under this alternative.	Projected average annual direct employment would be 1,098 logging jobs and 823 sawmill jobs under this alternative.
Recreation and Tourism: Employment projections are based on a linear projection of demand and projected supply based on changes to ROS settings (see above). Projections are average annual equivalents for the next 10 years, based on the estimated non-resident share of recreation and tourism activity. These totals do not include indirect or induced employment effects.	Projected average annual direct employment would be 4,327 jobs under this alternative.	Projected average annual direct employment would be 4,323 jobs under this alternative.	Projected average annual direct employment would be 4,321 jobs under this alternative.	Projected average annual direct employment would be 4,312 jobs under this alternative.	Projected average annual direct employment would be 4,319 jobs under this alternative.	Projected average annual direct employment would be 4,319 jobs under this alternative.	Projected average annual direct employment would be 4,310 jobs under this alternative.
Salmon Harvesting and Processing: There is not expected to be any significant change to the commercial fishing or fish processing industries over the next decade as a result of National Forest activities.	The Forest Plan Riparian and other S&Gs and monitoring are expected to reduce the effects of potential development activities on fish passage and habitat to low levels over the long-term and are not expected to have significant effects on the commercial fishing and fish processing industries.	Same as Alternative 1.	Same as Alternative 1.	Same as Alternative 1.	Same as Alternative 1.	Same as Alternative 1.	Same as Alternative 1.
Economic Efficiency Analysis							
Present Net Value (PNV): Economic efficiency analysis measures the costs and benefits to society associates with a given alternative. PNV figures are calculated by subtracting discounted costs from discounted benefits to yield a net value. PNV is calculated for those costs and benefits that can be assigned monetary values, in this case timber, recreation and tourism, and program management costs.	The estimated PNV for this alternative is $7,112 million.	The estimated PNV for this alternative is $6,884 million.	The estimated PNV for this alternative is $6,782 million.	The estimated PNV for this alternative is $6,472 million.	The estimated PNV for this alternative is $6,657 million.	The estimated PNV for this alternative is $6,662 million.	The estimated PNV for this alternative is $6,294 million.
Non-Use Values: Non-use values are values that individuals assign to a resource independent of their use of that resource and include existence, option, and bequest values. These types of values are typically associated with undeveloped areas. Impacts to roadless areas are summarized above.	Approximately 1.2 million acres (7%) of the Tongass would be allocated to moderate and intensive development LUDs. Approximately 435,000 acres are estimated to be suitable for harvest.	Approximately 2.0 million acres (12%) of the Tongass would be allocated to moderate and intensive development LUDs. Approximately 563,000 acres are estimated to be suitable for harvest.	Approximately 3.0 million acres (18%) of the Tongass would be allocated to moderate and intensive development LUDs. Approximately 697,000 acres are estimated to be suitable for harvest.	Approximately 4.7 million acres (28%) of the Tongass would be allocated to moderate and intensive development LUDs. Approximately 1.01 million acres are estimated to be suitable for harvest.	Approximately 3.6 million acres (22%) of the Tongass would be allocated to moderate and intensive development LUDs. Approximately 809,000 acres are estimated to be suitable for harvest.	Approximately 3.6 million acres (22%) of the Tongass would be allocated to moderate and intensive development LUDs. Approximately 806,000 acres are estimated to be suitable for harvest.	Approximately 5.0 million acres (30%) of the Tongass would be allocated to moderate and intensive development LUDs. Approximately 1.15 million acres are estimated to be suitable for harvest.

CHAPTER 3

ENVIRONMENT AND EFFECTS

Environment and Effects

Introduction

This chapter combines the affected environment and environmental consequences discussions required by the National Environmental Policy Act (NEPA) implementing regulations (40 Code of Federal Regulations [CFR] 1500-1508). The discussions are combined so that the environmental consequences (effects) of the alternatives on forest resources and the background information needed to understand these consequences are discussed together for each resource. Each resource is first described by its current condition, uses, supply, and demand, or expected use, along with an explanation of how each resource is measured and evaluated. The descriptions are limited to providing the background information necessary for understanding how the Environmental Impact Statement (EIS) alternatives may affect the resource. Methodology and scientific accuracy is discussed for most resources.

Many of the relationships established and discussed in the 1997 Tongass Forest Plan Revision Final EIS and in the 2003 Supplemental EIS (SEIS), in particular, Chapter 3 of these documents, are still valid and, therefore, are incorporated by reference in this EIS. However, this EIS uses updated relevant information to better reflect current conditions and focuses on the potential effects most relevant to the potential changes that could occur from proposed amendment to the current Tongass Forest Plan standards and guidelines and Land Use Designations (LUDs).

Analyzing Effects

Following each resource description is a discussion of the potential effects (environmental consequences) to the resource associated with implementation of each EIS alternative. All significant or potentially significant effects, including direct, indirect, and cumulative effects, are disclosed. Effects are quantified, where possible, although qualitative discussions are also included. The means by which any identified potential adverse effects will be reduced or mitigated are also described.

Environmental consequences are the effects of implementing an alternative on the physical, biological, social, and economic environment. Direct environmental effects are defined as those occurring at the same time and place as the initial cause or action. Indirect effects are those that occur later in time, or are spatially removed from the activity but would be significant in the foreseeable future. Cumulative effects result from the incremental effects of actions, when added to other past, present, and reasonably foreseeable future actions, regardless of what agency (federal or non-federal) or person undertakes such other actions. Cumulative effects can result from individually minor, but collectively significant, actions taking place over a period of time.

Potential adverse environmental effects that cannot be avoided are discussed. Unavoidable adverse effects are those resulting from managing the land for one resource at the expense of the use or condition of other resources. Many adverse effects can be reduced or mitigated by limiting the extent or duration of effects. The current Tongass Forest Plan is designed to mitigate potential adverse effects on forest resources and uses, especially through its mix of management prescriptions and Forest-wide standards and guidelines. Mitigation measures within standards and guidelines are specified for project activities to be implemented under the current Tongass Forest Plan.

Short-term uses, and their effects, are those that occur annually or within the first 10 years of Forest Plan implementation. Long-term productivity refers to the capability of the land and resources to continue producing goods and services for 50 years and beyond. Long-term and cumulative effects may be projected out 100 years or more, as needed, to fully analyze the potential consequences for particular resources.

Irreversible and irretrievable resource commitments are normally not made at the programmatic level of a Forest Plan. Irreversible commitments are decisions affecting nonrenewable resources, such as soils, minerals, plant and animal species, and heritage resources. Such commitments of resources are considered irreversible because the resource has deteriorated to the point that renewal can occur only over a long period of time or at a great expense, or the resource has been destroyed or removed. While the application of LUDs allowing land-altering activities can indicate the potential for such commitments, the actual commitment to develop, use, or affect nonrenewable resources is made at the project level. The gradual decline in old-growth habitat may be considered an irreversible commitment.

Irretrievable commitments represent opportunities foregone for the period during which resource use or production cannot be realized. These decisions are reversible, but the production opportunities foregone are irretrievable. An example of such commitments is the allocation of LUDs that do not allow timber harvest to areas containing suitable and accessible timberlands. For the time over which such allocations are made, the opportunity to obtain timber from those areas is foregone, thus irretrievable. Irreversible and irretrievable commitments are not identified, as such, in the discussions.

For estimating the effects of alternatives at the programmatic Forest Plan level, the assumption is made that the kinds of resource management activities <u>allowed</u> under the LUDs will in fact occur to the extent necessary to achieve the goals and objectives of each alternative. The actual location, design, and extent of such activities are, however, not known at this time because that is a project-by-project decision. In many cases, the discussions refer to the <u>potential</u> for effects to occur, realizing that in many cases these are only estimates.

The effects analysis is useful in comparing and evaluating alternatives, but should not be applied per se to any specific location within the Forest. Land management plans are tools for further agency planning and guide, but do not direct future management activities. The land management plan is a strategic plan that establishes a long-term management framework for the Tongass National Forest. Within that framework, specific projects and activities will be proposed, approved, and implemented depending on specific conditions, budgets, needs, proposals, and circumstances at that time. The plan can only speculate about the projects that may be proposed and budgeted and the events that may occur that will force changes in the projects and the effects of these projects. Thus, the effects presented here are comparative in nature. Specific effects that can be meaningfully measured and evaluated generally occur at the project and activity stage.

A strong effort was made throughout the current Tongass Forest Plan development process to obtain and use the best available information to evaluate and compare the effects of alternatives. NEPA implementing regulations (40 CFR 1502.22) state that when "there is incomplete or unavailable information, the agency shall always make clear that such information is lacking." This was done where appropriate. The NEPA requirement goes on to say that if the incomplete information "is essential to a reasoned choice among alternatives" then considerations, such as the cost of obtaining it, apply. The 1997 Tongass Forest Plan Revision Final EIS, the 2003 SEIS, and this EIS, along with their planning records, will provide the Forest Supervisor and Regional Forester with the "essential" information needed to make a reasoned choice among alternatives.

Cumulative Effects

As noted above, cumulative effects result from the incremental effects of actions, when added to other past, present, and reasonably foreseeable future actions, regardless of what agency (federal or non-federal) or person undertakes such other actions. For this analysis, the region or study area considered for cumulative effects varied according to the resource being assessed.

For most aquatic or watershed-related resources, the area within the proclaimed Forest boundary (approximately 17.87 million acres, including 1.09 million acres of non-National Forest System [NFS] lands) was used, as defined by the Value Comparison Unit (VCU) map (see below for more detail on VCUs and see the VCU map on the CD version of this EIS). VCUs generally correspond with watersheds so basing the analysis of cumulative effects on watershed boundaries is most relevant to aquatic and watershed-related resources.

For wildlife and other terrestrial resources, all of Southeast Alaska from Yakutat Bay southeast to the southeastern end of Alaska (approximately 21.56 million acres, including 4.79 million acres of non-NFS lands) was used as the study area, although some analyses were based on the area within the Forest boundary, depending on the availability and quality of available information. The Southeast Alaska area includes all of Glacier Bay National Park and the State, Bureau of Land Management, and other lands in the vicinity of Haines and Skagway. Often Wildlife Analysis Areas (WAAs) were used to summarize information within these study areas (see below for more detail on WAAs and see the WAA map on the CD version of this EIS). In addition, biogeographic provinces and ecological subsections (see descriptions below) were also used to summarize cumulative effects information for wildlife and other terrestrial resources.

For social and economic, recreation, and related human uses, all of Southeast Alaska and beyond, were given consideration for cumulative effects, especially regarding economic, market, and other factors.

Cumulative effects analyses are presented throughout the effects sections. Many times, direct and indirect effects are presented in the context of past, present and future actions. For example, many of the analyses address past harvest and road construction on NFS lands along with future NFS harvest and road construction. These are cumulative effects analyses because they deal with past, present, and reasonably foreseeable actions on NFS lands. These are typically presented under Direct and Indirect Effects because it is logical to discuss the harvest and road construction plans along with the past harvest and road construction on the lands where the proposed action will take place. However, there are specific cumulative effects sections that reference these analyses and present additional analyses that take into account past, present, and future harvest and road construction on non-NFS lands when added to the NFS land harvest and road construction.

Generally, for the physical and biological resources, the actions considered in assessing cumulative effects included the following:

- Past, present, and future timber harvest and road construction on NFS lands;

- Past, present, and future timber harvest on adjacent private, state, and Native corporation lands. (These usually represent more intensive harvest and road development than for NFS lands; however, consideration was given to the Alaska Forest Resources and Practices Act which is designed primarily to protect fish habitat and water quality and promote rapid reforestation);
- Existing mining at Greens Creek on Admiralty Island and other existing sites, as well as possible future sites, including the proposed Kensington Mine at Berners Bay north of Juneau;
- Electrical intertie and other utility corridor construction, including the Swan Lake-Lake Tyee Transmission Intertie project;
- Regional transportation development as defined by the State Transportation Plan;
- Growth in the cruise ship and guiding industries and general outdoor recreation. Development of fishing and other lodges;
- Human settlements – expansion of cities like Juneau and Ketchikan. Also, recreational cabin development and land auctions by the State; and
- Existing and limited future hydroelectric developments (e.g., Angoon hydroelectric project).

Geographic Information System Database and Quantification for this EIS

The Forest Service developed a computerized geographic information system (GIS) database for the revision of the Tongass Forest Plan, and that system continues to be improved upon and used. This system makes it possible to conduct spatial analysis of alternatives and effects, and to rapidly display resource information in map format. The GIS is a very large database, containing information on many of the resources of the Forest. Much of the data consist of map “layers,” each representing a particular resource or attribute (such as forest type, soil type, or recreation places). Numerical data can also be stored, displayed, and analyzed. Computer technology and capability continues to improve and the Forest GIS program, especially at the project level, reflects such growth. Additional information, as well as improved information, is now available for many resource areas. This EIS takes advantage of the new technology capability and information. This EIS validated and updated various GIS layers used in the 1997 Forest Plan Revision Final EIS and the 2003 SEIS. This existing condition information is what has been used as a baseline for the EIS and Alternative 5, No Action.

The baseline numbers used in Alternative 5 do not always match the numbers for Alternative 11 of the 1997 Forest Plan Revision Final EIS, which is the 1997 alternative that is most like the current Forest Plan. This is primarily because of ongoing management of the Tongass National Forest. Examples include changes in land ownership, changes in resource conditions resulting from timber harvest and road construction, and nonsignificant amendments to the 1997 Forest Plan Revision Final EIS. In addition, the use of newer computer mapping and measurement techniques that are more accurate than earlier methods also affects the numbers. In general, the relative differences among the 1997 Forest Plan Revision Final EIS-generated numbers, the 2003 SEIS-generated numbers, and the baseline numbers used in this EIS are small, and do not affect the analysis relationships among these documents.

It should be noted that in some cases where the acreages are measured that depend on overlaying of multiple coverages, the acreage measurements for individual categories sometimes need to be adjusted to account for the fact that coverages do not always line up exactly in places where they should (e.g., along property boundaries, saltwater shorelines, lake edges). Very slight misalignment of the coverages can result in polygon slivers between the coverages, which can produce acreage differences initially. These differences can amount to tens or hundreds of acres or more, especially because we are dealing with such a large area (i.e., 17 million acres). However, on a percentage basis, these slivers and the adjustments that are necessary are insignificant.

It should also be noted that the figures presented are generally rounded to the nearest whole acre, whole mile, or whole percent. No attempt has been made to adjust the numbers to force the sums of rounded numbers to equal the expected totals. Therefore, the sum of rounded individual numbers will often be one digit higher or lower than the expected sum. The sums that are presented are the sums of the unrounded numbers.

Land Use Designation Groupings

For many resources, the effects and the differences in effects among the alternatives are best identified through the LUD allocations. While each LUD has a different purpose and management emphasis, many are similar in the kinds of effects they would potentially create. Based on this concept, and in order to simplify the identification of effects, the LUDs have been grouped into four categories: Wilderness, Natural Setting, Moderate Development, and Intensive Development. For some analyses, the LUDs are grouped into two categories: Wilderness and Natural Setting LUDs make up the non-development LUDs and Moderate and Intensive Development LUDs make up the development LUD category. Note that the Minerals and Transportation and Utility System LUDs are overlay LUDs and are managed according to the underlying LUD until such time that development is approved, if at all. Therefore, acreages in this EIS generally reflect the underlying LUD acreages. Table 3.1-1 displays these LUD groupings.

Land Divisions

The land area of the Tongass National Forest has been divided in several different ways to describe the different resources and how they are affected by Forest Plan alternatives. These divisions vary by resource because the relationship of each resource to geographic conditions and zones also varies. Several of these divisions are described briefly here.

Geographic Provinces

These are seven large land areas that are distinguished by differences in ecological processes. They are defined by a combination of climatic and geographic features. Geographic provinces are used in the evaluation of Research Natural Areas and Wild and Scenic Rivers. See the *Research Natural Areas* section of the 1997 Forest Plan Revision Final EIS for a description of each province.

Biogeographic Provinces

Biogeographic provinces are areas within which certain kinds of plants and animals tend to occur together. They are defined by a combination of similarity in species, patterns of distribution of species, and natural characteristics or barriers. Twenty-one biogeographic provinces occur on the Tongass. They are used in the *Biodiversity* and *Wildlife* sections and described in the *Biodiversity* section of this chapter.

Table 3.1-1
Land Use Designation Groupings Used to Discuss Effects

LUD Group	Land Use Designation
Non-development LUDs	
Wilderness LUD Group	Wilderness Wilderness National Monument Nonwilderness National Monument
Natural Setting LUD Group	LUD II Remote Recreation Semi-Remote Recreation Old-Growth Habitat Enacted Municipal Watershed Research Natural Area[1] Special Interest Area[1] Wild River[1] Scenic River Recreational River
Development LUDs	
Moderate Development LUD Group	Experimental Forest Scenic Viewshed Modified Landscape
Intensive Development LUD Group	Timber production
Overlay LUDs[2]	
Overlay LUD Group	Minerals Transportation and Utility Systems

[1] These three LUDs function as overlay LUDs (see footnote 2) when they occur within Wilderness, Wilderness National Monument, or LUD II areas.
[2] The Minerals and Transportation and Utility Systems (TUS) LUDs are overlay LUDs. Areas allocated to these LUDs are managed according to the underlying LUD until such time that mineral or transportation or utility development is approved, if at all. Generally, acreages in this EIS do not include the Minerals or TUS LUDs, but rather the underlying LUD.

Ecological Sections and Subsections

Ecological sections and subsections are two classification levels within a hierarchical system for subdividing ecosystems according to the National Hierarchical Framework of Ecological Units (see *Biodiversity* section of this chapter).

The framework consists of eight nested mapping levels that serve a variety of purposes. Within the hierarchy, ecological sections characterize medium to large ecosystems (on the order of 1,000 square miles) and ecological subsections characterize mid-sized ecosystems (10 to 1,000 square miles). Fourteen ecological sections and 73 ecological subsections occur on the Tongass.

Value Comparison Units

Value Comparison Units (VCUs) are distinct geographic areas, roughly analogous to watersheds, each encompassing a drainage basin containing one or more large stream systems. The boundaries usually follow watershed divides. VCUs were used for the 1979 Tongass Forest Plan and have since been updated. The Forest currently has about 945 VCUs averaging 18,000 acres in size. They are used to describe the locations of specific resources on the Forest. A map of the VCUs on the Tongass is provided on the CD version of this EIS.

Wildlife Analysis Areas

Wildlife Analysis Areas (WAAs) are land divisions used by the Alaska Department of Fish and Game (ADF&G). Approximately 190 WAAs apply to the Tongass National Forest; they average slightly less than 90,000 acres in size. In general, WAA boundaries correspond with VCU boundaries and they typically include three to eight VCUs (averaging just under five). They are used in the *Subsistence* and *Wildlife* sections. A map of the WAAs on the Tongass is provided on the CD version of this EIS.

General Forest Description

A brief description of the physical, biological, and socioeconomic settings of the Tongass National Forest is presented in this section. Chapter 1 and the alternative maps include a vicinity map.

Physical Setting

The mainland and many of the islands of Southeast Alaska are mountainous, often rising abruptly from sea level to several thousand feet. Elevations of forested areas extend up to approximately 3,000 feet in the southern sections of the Tongass National Forest and up to 2,500 feet further north. The mountain valleys provide reservoirs for huge ice fields and glaciers, located primarily on the mainland.

More than 1 million years ago, all but the highest mountain peaks and some outer coastal areas in Southeast Alaska were covered by ice. The great erosional powers of these vast expanses of ice molded and shaped the landscape as the glaciers moved downhill under their own weight, carving the bedrock below them. When the ice receded and uncovered the land, the more resistant mineral-rich rocks remained, revealing a network of islands dissected by numerous streams, U-shaped valleys, and fiords. This modification by glaciers gives Southeast Alaska's landscape its unique character.

The configuration of the coastline, the warm Japanese ocean current, and the high coastal mountains provide the factors necessary to produce abundant rainfall. The annual precipitation of Southeast Alaska averages more than 100 inches throughout. Precipitation is highest in the southern areas and decreases as one moves north. At higher elevations, more than 200 inches of snow may fall annually, perpetuating the existing ice fields and glaciers. Storms and moderate to heavy precipitation occur year-round, but most commonly from September through November. The abundant moisture feeds numerous streams, rivers, and lakes that dot the landscape.

Southeast Alaska has a maritime climate, resulting from the moderating influence of the Pacific Ocean. In the summer, this provides a cooling influence, while in winter, temperatures are warmer than would be expected for these latitudes. Normal temperatures range from mid-40 degrees Fahrenheit (°F) to mid-60 °F in the summer, and from the high teens to the low-40s in the winter. During the warmer months, temperatures are highest inland and lowest along the coasts, while in the colder months, the reverse is true.

Biological Setting

The coastal forest of Southeast Alaska is part of the cool, temperate rain forest that extends along the Pacific coast from Northern California to Cook Inlet in Alaska. Most of the Forest is composed of old-growth conifers, primarily western hemlock and Sitka spruce, with a scattering of mountain hemlock, western redcedar (in the south), and Alaska yellow-cedar. Red alder is common along streams, beach fringes, and on soils recently disturbed by management activities and landslides. Black cottonwood grows on the floodplains of major rivers and recently deglaciated areas.

Blueberry, huckleberry, Sitka alder, Devil's club, and salal are common shrubs in the Forest. The Forest floor is composed of plants, such as deerheart, dogwood, single delight, and skunk cabbage. Because of the high rainfall and resulting high humidity, mosses grow in great profusion on the ground, on fallen logs, on the lower branches of trees, and in forest openings.

Grass-sedge meadows usually lie at low elevations, often along the coast. Stands of willows border many of the stream channels. Muskeg (bog plant) communities, dominated by sphagnum mosses and sedges, occur throughout the Forest.

The alpine zone usually lies above 2,500 to 3,000 feet. It occupies the area above the coastal forest and is separated from the Forest by a subalpine or transition zone. Resident plants have adapted to snowpack and wind abrasion by evolving low-growth forms. Low, mat-forming vegetation covers most of the area, with cushion-like plants occupying crevices on exposed rock outcrops and talus slopes.

The forests, shorelines, streams, and rivers of Southeast Alaska provide habitat for over 300 species of birds and mammals, including game and non-game animals, such as brown and black bear, Sitka black-tailed deer, moose, wolf, mountain goat, beaver, otter, and marten. The coastline provides ideal habitat for a large population of bald eagles, and wetlands provide nesting habitat for many waterfowl.

A highly productive marine environment includes an abundance of marine mammals, halibut, herring, and hundreds of shellfish. Both resident and anadromous fish are found within and adjacent to the Forest.

Socioeconomic Setting

Southeast Alaska's communities and individuals make up a variety of cultures. The abundant resources of the forests and waters have provided food, shelter, and livelihood for its peoples for thousands of years. The first inhabitants of the area, the Tlingit and Haida, adapted well to the coastal environment and developed a rich culture. The numerous waterways allowed for mobility, which aided in expanding trade and gathering food.

In the 1700s, Russian exploration began in Alaska. The fur trade, primarily sea otter pelts, was the main force driving colonization. When most of the sea otter populations were depleted, the fur industry declined and Russia lost interest in its North American colony. Alaska was sold to the United States in 1867.

Colonization continued under U.S. ownership, and new industries developed. In the late 1800s, commercial fish canning became an important part of the economy of Southeast Alaska. During that same period, the discovery of gold brought thousands of miners to the area, and many were followed by their families. The most important of the early gold discoveries occurred in Juneau. In the early 1900s, the Depression brought a decline in mining employment, and the impact of World War II resulted in the closures of the last remaining mines.

The timber resource was used by the earliest inhabitants in a variety of ways. The Russians harvested timber for building ships and structures, but commercial timber harvest was not developed until the 1900s. In the earlier part of the century, small timber mills operated in a few communities. During the 1950s, two large-scale pulp mills were developed in Ketchikan and Sitka, and the timber industry became a major economic component of Southeast Alaska's economy.

In the 1950s, Alaska focused its attention on statehood, and on January 3, 1959, became the 49th state of the United States. This resulted in an increase in government employment and, coupled with the growth of the timber industry, a gradual shift towards a more diversified economy, with less dependence on nonrenewable resources.

More than 70,000 people live in the towns, communities, and villages of Southeast Alaska. Most of the region's population is concentrated in a few communities, the largest being Juneau, Ketchikan, Sitka, and Petersburg. Services, state and local government, and retail trade were the largest economic sectors by employment in Southeast Alaska in 2005, accounting for 28, 21, and 12 percent of total employment, respectively. Employment in natural resource-based industries remains important in many of the region's communities. Tourism, which has increased in recent years, provides another important source of regional employment and income. Many small, rural communities continue to depend primarily on fishing, timber production, and subsistence uses.

Organization of Chapter 3

The remainder of Chapter 3 is divided into three parts. First, the resources that make up the physical and biological environment are described and the effects of the alternatives are analyzed. This part sets the stage for the next part—the evaluation of human uses and land management. Finally, both of these parts set the stage for the final part—the economic and social environment. The focus is on significant effects, with the analysis centered on the public issues related to the Forest Plan amendment.

Physical and Biological Environment

Climate and Air

Affected Environment

Climate

The Tongass National Forest occupies a series of islands and a narrow strip of the mainland between the Pacific Ocean and the crest of the coastal mountains. The configuration of the coastline, the warm Japanese ocean current, and the high coastal mountains combine to produce a cool, wet environment. Precipitation at sea level in Southeast Alaska ranges from 30 inches per year at Skagway to 220 inches per year at Little Port Walter. Precipitation increases with elevation. It is estimated that the average annual precipitation may be as high as 400 inches on the mountains of southern Baranof Island and about 260 inches over the Juneau Icefield. Southeast Alaska has complete cloud cover approximately 85 percent of the year. Snowfall varies according to elevation and distance inland from the coast. October is generally the wettest month. May through July are, on average, the drier months. The Pacific maritime influence holds the daily and seasonal temperatures within a narrow range. Temperatures average 32 degrees Fahrenheit (°F) in the winter and 60°F in the summer. During the warmer months, temperatures are highest inland and lowest along the coasts, while in the colder months, the reverse is true. Storms and moderate to heavy precipitation occur year-round, but most commonly from September through November. The abundant moisture supports an extensive temperate rain forest and feeds numerous streams, rivers, and lakes, which in turn provide valuable fish habitat.

Climate Change

Southeast Alaska has had considerable year-to-year and decade-to-decade variability in its weather, associated with large-scale shifts in ocean temperatures, salinity levels, and ice conditions. Even with these short-term variations in weather, some longer-term trends are evident. Southeast Alaska's climate has shown a strong warming trend since the middle of the 19th century (the end of the little ice age), as has much of the northern hemisphere. This trend accelerated in the late 1970s due to cyclical shift of the Pacific decadal oscillation (Parson et al. 2001). In addition to this natural change, anthropogenic change (human-caused change) has accelerated climate changes during the last several decades (Intergovernment Panel on Climate Change [IPCC] 2007).

Changes to the climate in Southeast Alaska have already resulted in changes to ecosystem processes and services on the Tongass National Forest. The number of days with gale-force winds has more than doubled since 1950 (U.S. Global Change Research Program [USGCRP] 2003). Juday et al. (1998) state that as of their report, the increased frequency of storms had not corresponded to an increase in large-scale blowdowns in Southeast Alaska, although the authors state that they do not know if it resulted in an increase in canopy gap formation. The 2006 Forest Health report noted very little blowdown in aerial and ground surveys (USDA Forest Service and ADNR 2007)

The Muir Glacier has retreated more than 9 miles since 1941, exposing large areas of bare rock that are starting to colonize with alder and willow. Warmer summers have led to longer growing seasons for trees and other vegetation. Warmer winters have meant more insects survive the winter, triggering insect outbreaks that affected trees on over 300,000 acres of forest in Southeast Alaska (including all ownerships) during the 1990s (USGCRP 2003). The warming trend has also reduced snowpack in low-elevation areas, which may contribute to ongoing yellow-cedar decline affecting over 500,000 acres in Southeast Alaska (Hennon and Shaw 1997). Drier summers may have contributed to the number and duration of low stream flow episodes, which can adversely affect salmon, and the increase in the amount of precipitation falling as rain instead of snow since the 1970s has reduced the frequency of low- and moderate-elevation avalanches, allowing mountain hemlock to colonize some alpine areas (Parson et al. 2001).

There are several models that have attempted to predict future trends in Alaska's climate. Most models predict warmer, wetter weather for Alaska and they generally agree that rainfall will increase and snowfall will decrease at lower elevations in Southeast Alaska over the next 50 to 100 years (Bonsal and Prowse 2006). However, these models do not always agree on the extent of climate change in Southeast Alaska. For example, two models were compared in a study by Parson et al. (2001), one from the Canadian Climate Center and the other from the Hadley Center. Both predict rising temperatures and a 10 percent decrease in summer precipitation in some portions of Southeast Alaska, but the models differ in projecting the areas affected. The Canadian scenario predicts that drier summer weather will extend across all of Southeast Alaska, while the Hadley scenario predicts that these effects will be confined to the extreme southeast. Both models predict the expansion of forests into higher elevation areas, as well as increased insect problems and decreased soil moisture, due to increased evaporation during warmer, drier summer weather. These factors may lead to an increase in fire frequency and adversely affect fish. These models are not specific to Southeast Alaska; therefore, the predicted effects may not be relevant for Southeast Alaska. While the 2007 report by the Intergovernmental Panel on Climate Change (IPCC 2007) predicts higher stream runoff at the higher latitudes, as well an increase in heavy precipitation events, a decrease in glacier size, and a slight increase in tree growth, it also concludes that not all areas will be effected the same and limits forecasts to large regions, such as western North America.

A scientific panel on climate change convened by the City and Borough of Juneau (Kelly et al. 2007) has made some site-specific predictions based on a review of several models. They concluded that the Juneau area will see overall warmer and wetter weather, particularly in fall and winter. The Juneau Icefield will continue to retreat. Global sea level will continue to rise as a result of the melting of glaciers and ice sheets and the warming of ocean waters (thermal expansion). Over the next century, global sea level is projected to rise 0.3 foot to 3.0 feet. In the City and Borough of Juneau, however, the land surface is rising as a result of the loss of glacial ice (isostatic rebound), and the rate of uplift is greater than the projected rate of global sea level rise. Over the next century, the relative sea level in the Juneau area likely will decrease between 1.0 and 3.6 feet.

Carbon Sequestration

Carbon, primarily in the form of carbon dioxide, is one of the major greenhouse gases being released into the atmosphere (McPherson and Simpson 1999). The global carbon cycle involves the earth's atmosphere, fossil fuels, the oceans, and the vegetation and soils of the earth's terrestrial ecosystems. Gases that make up the earth's atmosphere, such as carbon dioxide, methane, nitrous oxide, and water molecules, trap the sun's heat, creating a natural "greenhouse effect" that makes life on earth possible (McPherson and Simpson 1999). These gases are released into, and removed from, the atmosphere by a variety of natural sources and sinks.

The Tongass National Forest, like most forests, is considered a carbon sink, storing more carbon in its systems than is released by natural processes. As such, a critical ecosystem service sustained by the forest is *carbon sequestration*, or removal of carbon dioxide from the atmosphere and keeping that carbon inactive by storing it in biomass (live and dead plant structures, primarily) and soil organic matter. D'Amore and Lynn (2002) believed that previous methods may have underestimated the amount of carbon stored in Southeast Alaska. Subsequently, Smith et al. (2004a) estimated that mature hemlock-Sitka spruce forests of the Pacific Northwest store 184.4 tons of carbon per acre. Leighty et al. (2006) estimate that the Tongass contains approximately 2.8 billion metric tons of carbon in both above and below ground living and dead material (an estimated 83,500,000 billion metric tons of carbon are stored world-wide, primarily in the oceans and marine sediment, based on United Nations estimates). Leighty et al. (2006) also estimate that between 6.4 and 17.2 million metric tons (0.2 to 0.6 percent) of stored carbon has been lost on the Tongass since timber harvest began in the early part of the 20th century. For comparison, approximately 4.5 million metric tons of carbon was released every day to produce electric power in the United States in 2005 (DOE 2006).

Generally, the capacity for a system to sequester and store carbon depends on the location, age, and species mix of the forest (Birdsey et al. 1993). Newly established forests accumulate carbon rapidly for many years, slowing as trees mature, growth slows, and decaying material accumulates. However, the cool conditions on the Tongass inhibit decomposition, drastically slowing biomass breakdown and carbon release. Decaying plant matter is incorporated into the system's soil profile, where it accumulates and may reside indefinitely. As a result, old forests generally store considerable amounts of carbon on the forest floor, approximately 70 tons per acre in hemlock-Sitka spruce ecosystems (Smith et al. 2004a). Janisch and Harmon (2002) suggest that it can take more than 200 years following timber harvest for forests to reach equilibrium, the point where carbon released from decay equals carbon stored in the system.

Interest in enhancing ecosystem carbon sequestration and storage has intensified recently, as concerns about how to mitigate climate change have increased. This question of how active ecosystem management may contribute to, or detract from, the mitigation effort is being explored, with varying results. A few studies have shown that management of some forests with certain parameters being met, such as fertilization, may result in heightened capacity for carbon sequestration and storage (Schroeder 1991, Binkley et al. 1997). A study in the eastern United States found that thinning a 50-year-old stand from below (removing the smallest trees) resulted in more stored carbon after 25 years than resulted from thinning stands from the middle or from above (Hoover and Stout 2007). A recent Pacific Northwest study (Perez-Garcia et al. 2005) concluded that the use of wood resulted in "significant atmospheric carbon reductions by displacing more fossil fuel-intensive products in housing construction." They estimate that a rotation of 80 years would sequester the most carbon. Other studies, particularly two with application to Southeast Alaskan ecosystems (Harmon et al. 1990, Leighty et al. 2006), indicate that the

Tongass would generate a net loss of carbon to the atmosphere if active harvest of old growth is pursued. Ultimately, a net loss or gain of carbon in active management situations depends on use of harvested timber, the substitute material available, the amount of carbon emitted in harvesting activities, and the amount of carbon emitted via decomposition of on-site wood waste and soil organic matter losses. If the emissions are less than the carbon stored in utilized wood, and if the system can rapidly replace losses from decomposition through tree growth, the activity may yield a net gain of stored carbon. Whether active management of old-growth forests on the Tongass results in a net gain or loss of carbon is currently unknown.

In addition to the effects of timber management, climate change may also affect carbon sequestration in Southeast Alaska. D'Amore and Lynn (2002) note that numerous studies have shown that carbon stored in soils, including peatlands, may be released to the atmosphere in the form of carbon dioxide or methane as climate warms and that dissolved carbon may be transported to streams and the ocean due to increased rainfall. If warmer, wetter conditions occur, climate change could result in additional carbon losses.

Air Quality

The air quality of Southeast Alaska and the Tongass National Forest is generally good. The prevalent airflow from the Pacific Ocean, the relatively small amount of industrial development in Southeast Alaska, the lack of large population centers, the absence of slash burning following harvest, and environmental regulations all contribute to maintaining clean air. Forest activities have historically had little direct effect on air quality on the Tongass (USDA Forest Service 1997a). However, cruise ship emissions in certain locations and trans-Pacific pollutants such as persistent semi-volatile organic pollutants and greenhouse gases are a growing concern.

Air quality and sources of air pollution on the Tongass are described in Air Quality Monitoring on the Tongass National Forest: Methods and Baselines Using Lichens (Geiser et al. 1994) and Air Quality Biomonitoring with Lichens-Tongass National Forest (Dillman 2007). The Tongass has 127 permanent lichen biomonitoring plots that can be used to detect possible trends in the elemental content of lichen tissue and changes in lichen communities over time. Lichen biomonitoring plots are distributed across the Forest, including all but one Wilderness. Lichens serve as dynamically representative samples of the environmental conditions in which they are growing. Elements and compounds in the air are absorbed by lichens along with moisture from the surrounding environment and become concentrated in the lichen tissue. Roughly 10 percent of the biomonitoring plots on the Tongass were recently re-visited, all in wilderness areas. Little or no change in the elemental content of the lichens was detected between the first monitoring effort (Geiser et al. 1994) and the recent one (a span of about 15 years). Provisional threshold levels were generated from the most pristine areas on the Tongass for 27 elements, including sulfur and nitrogen, in four target lichen species (Dillman 2007). A provisional threshold level is the level of a pollutant of interest per lichen species that can be expected at a clean air site on the Tongass (expressed in parts per million, or ppm). Nearly half of the 127 biomonitoring plots are elevated above the threshold level in one or more elements due to natural or anthropogenic sources. Natural sources include the mineral content of the local rock and soil and salt spray from the ocean (a major factor in sites near the coast). Anthropogenic sources include dust from roads (the most comment human-cause source) as well as wood stoves, fossil fuels (specifically near Juneau), and mining (specifically near the Greens Creek Mine). Monitoring plans call for lichen biomonitoring to be done on a 5 to 10 year interval to better detect pollution trends, especially for trans-Pacific sources of nitrogen.

The Tongass National Forest partnered with the National Park Service Western Airborne Contaminants Assessment Program (WACAP), which quantifies regional and trans-Pacific semi-volatile and persistent organic pollutants in lichens, vascular plants, and other organisms. Results from the WACAP samples collected from the Stikine-LeConte Wilderness are being analyzed by the National Park Service. An aerosol sampler near Petersburg was installed in 2004 as part of the Interagency Monitoring of Protected Visual Environment (IMPROVE) program. This is the only IMPROVE site in Southeast Alaska, with the next nearest station in Tuxedni Wilderness near Anchorage. Data from the IMPROVE site will be collected for 5 years to observe trends and to determine regional, state, and national significance.

Visual inspections of cruise ship emissions by rangers in Tracy Arm/Fords Terror Wilderness occur during the summer tourist season as part of an agreement with the State using U.S. Environmental Protection Agency (EPA)-approved methods. Also, the Tongass is working with the National Park Service in the Southeast Alaska Network and Forest Service Air Resource Program in Region 6 to coordinate a Southeast Alaska cruise ship emissions monitoring effort using passive air samplers in remote locations.

Juneau Air Quality

Juneau's Mendenhall Valley is the only area in Southeast Alaska that is known to have exceeded National Ambient Air Quality Standards. The EPA listed Juneau City and Borough as a non-attainment area for particulate matter less than or equal to 10 micrometers in 1990. The area is classified as Moderate for this component of air quality, with an average daily rating of 110 out of a maximum of 500. Monitoring data indicate that air quality in Juneau has met state and federal ambient air quality standards in recent years. No state or federal ambient air quality standards have been exceeded since 1997. The last time particulate matter standards were exceeded in Juneau was in 1993. The State and EPA are currently considering re-designating the Juneau area as a maintenance area, an area in transition between non-attainment and attainment (Alaska Department of Environmental Conservation [ADEC] 2007). The ADEC has conducted ambient air monitoring in other locations in Southeast Alaska. These studies indicate these areas are within national standards for the pollutants monitored.

Lichen tissues were collected on Mt. Roberts in the downtown Juneau area at five different elevations as part of the Tongass lichen biomonitoring program and in collaboration with the State. The lichen tissues analyzed were elevated above provisional threshold levels in all five plots in three or more elements including sulfur, nitrogen, and heavy metals. Lichens from the plot at 175 feet above sea level had the greatest number of elements above threshold (12), indicating that the sources are probably local and anthropogenic (Dillman 2007).

Sources of Air Pollution

There are 36 stationary sources of air pollution in Southeast Alaska that require air quality control permits. These include diesel power plants, asphalt plants, incinerators, mining facilities, and other facilities. Some of these sources operate intermittently (e.g., back-up power plants may operate during power failures or during peak demand periods, and asphalt plants may operate seasonally), and others may be operating at full capacity (e.g., Greens Creek mine).

Other sources of air pollution in Southeast Alaska include mobile sources (such as cars, trucks, boats, cruise ships, airplanes, and helicopters) and area sources (such as home furnaces, wood stoves, and open burning). Under certain weather conditions, wildfires in Canada can affect air quality and visibility (i.e., regional haze) in parts of Southeast Alaska. The State issued an air quality advisory in July of 2004 due to extensive wildfires in western Canada.

Cruise ship traffic has greatly increased in Southeast Alaska over the last several years. More than 600 cruise ship visits occurred in Juneau during 2006, with an annual average number of visits of 591 ships for the 2003 to 2006 seasons. Cruise ship emission monitoring in Juneau by ADEC indicates that ship emissions are well within federal and state standards. The Mt. Roberts biomonitoring plots contain lichens that were elevated above threshold levels in three or more elements. Possible sources of the elevated elements are urbanization of downtown Juneau, past mining activities, and cruise ship emissions.

Cruise ship traffic in Tracy Arm creates a particular concern for air quality in Wilderness. Tracy Arm/Fords Terror Wilderness received more than 1,000 cruise ship visits between 2003 and 2006. Tracy Arm is less than a mile wide (on average) and is surrounded by high mountains. Cruise ship emissions may linger above the fiord for hours. The emissions are most heavily concentrated in upper Tracy Arm, where vessels stop near the South Sawyer Glacier for 1 to 4 hours (depending on ice conditions). Ship emissions often increase because of rapid changes in engine loading necessary for the ship to maneuver through ice and turn around. The Forest Service has received an increased number of public complaints concerning air quality within the Tracy Arm-Fords Terror Wilderness. In an effort to better address the air quality concerns in the Wilderness, the Forest Service and ADEC enters into a Memorandum of Understanding each year to train Forest Service wilderness rangers to visually monitor cruise ship emissions with EPA approved standards. ADEC annually reviews the visible emission observations and takes action on any that exceed the State Marine Vessel Emission standard (18 AAC 50.070).

Two lichen biomonitoring plots were established in 2003 near the entrance of Tracy Arm, where target lichen species are found. Results indicate no elements were elevated above threshold from this area of Tracy Arm (Dillman 2007). Future efforts to monitor air quality in the wilderness may utilize passive air samplers that measure SO_2, NHO_3, NH_3, and NO_X closer to where the cruise ships linger.

Environmental Consequences

Air Quality

Direct and Indirect Effects

The expected direct effects on air quality from forest management activities are temporary and limited in nature, resulting from dust and vehicular emissions from logging operations, administrative and harvest-related use of Forest roads, mineral development, and smoke from a limited prescribed fire program. None of the alternatives includes broadcast burning of slash following harvest. Alternatives 1, 2, 3, 6, 5, 4, and 7 would result in progressively more harvest, road construction, harvest-related vehicle use, and wood processing, as well as more emissions. No significant adverse effects on air quality are anticipated from these activities under any of the alternatives.

Indirect effects on air quality can result from the use of trees harvested from the Tongass National Forest, such as in the operation of industrial processing sites and firewood burning, as well as emissions from private vehicles using Forest unpaved roads. These indirect effects on air quality can be aesthetically displeasing or have potential health risks to both humans and the Forest. EPA and ADEC have regulatory responsibility, under the Clean Air Act, for air quality related to these kinds of sources. The enforcement of the applicable regulations by these agencies is anticipated to keep any potential adverse effects within the standards for air quality; therefore, no significant indirect effects from the uses of the Tongass National Forest should occur.

Carbon Sequestration

Estimating the effects of the proposed alternatives on carbon sequestration is complex. There are many factors that affect sequestration and storage; some components of an alternative contribute to a net removal of carbon, while some components offset those gains. Further, sequestration and carbon release happen at different time scales; therefore, while an activity may result in an immediate loss of carbon, over time, the net balance may reach zero or result in a net gain of storage.

It is generally assumed that old-growth forests considered for harvest in this analysis are currently in a "steady-state," meaning no net loss or gain of carbon. These systems are simply maintaining their storage capacity. Alternatives that propose less harvest, especially Alternatives 1 and 2, would allow this process to continue throughout most of the Tongass. In addition, much of the wood in harvested areas would be left in the Forest because there is no market for low-quality logs. Much of this wood, and the carbon it contains, would remain on the site as large woody debris for a long period of time under Alternatives 1 and 2.

Alternatives that harvest more old-growth forest have the potential to either increase or decrease the amount of stored carbon, depending on the time scale of consideration, how much of the wood is removed from the Forest for utilization, how the wood is used, and how much carbon is released in cutting, yarding, transporting, and processing the wood and in soil carbon and woody debris decomposition. Alternatives 4 and 7 have the potential to harvest the most wood and would convert both the saw timber and much of the utility wood into lumber and other building materials, such as medium density fiberboard (MDF board), assuming facilities to produce MDF board are built. This material would continue to store the sequestrated carbon for a relatively long period of time (perhaps 75 years), although this storage may be offset by harvest emissions and carbon released by on-site decomposition. If, on the other hand, the low-value logs are used to fuel bio-energy plants, carbon storage would be reduced. New stands would be regenerated and, in time, commercially thinned; these thinning activities may lead to a net gain or a net release of carbon as well, depending on how the thinning is conducted, how the products are used, and how much carbon is released during harvest, transportation, and processing. Alternatives 3, 5, and 6 are expected to be intermediate in their effects relative to Alternatives 4 and 7.

All alternatives include standards and guidelines that protect soils, such as limits on harvest on steep slopes, limits on roads built across steep slopes, and on soil disturbance. These measures would help retain carbon stored as organic material in the soil. Unlike many areas of the country, broadcast burning to reduce slash is not practiced on the Tongass; therefore, much more of carbon stored on the forest floor and in the upper layers of soil is retained compared to sites that are broadcast burned.

Cumulative Effects

Cumulative effects on air quality include harvest-related emissions from state and private land, vehicle and maritime emissions, permitted uses such as community incinerators, industrial operations, cruise ship emissions, and electricity generation. If plans for hydropower production and transmission lines linking communities are implemented, such as the Swan Lake-Lake Tyee project scheduled for completion in 2010, long-term reductions in both air pollution and carbon emissions could result because many communities would no longer rely on diesel generators. The Alaskan Energy Authority estimates that the Swan Lake-Lake Tyee intertie alone would reduce carbon dioxide emissions by approximately 486,000 tons and carbon monoxide by 3,150 tons by 2046 (comment letter submitted April 30, 2007). Most of the logs harvested on private land are expected to be exported; therefore, little additional emissions are expected due to processing wood from state and private land locally. Because of the temporary and limited effects associated with timber harvest on National Forest System (NFS) lands, the alternatives are not expected to contribute significantly to cumulative effects on air quality. Air pollution from wood processing is likely to remain low, but could increase somewhat if more wood is burned to produce energy. Air pollution from forest fires in western Canada could adversely affect air quality in Southeast Alaska, as occurred in 2004.

The cumulative effects from climate change alone and in combination with other stochastic events and with timber harvest are difficult to predict. Warmer temperatures are expected to result in a loss of carbon stored in leaf litter and soil organic matter, due to increased soil respiration (Bachelet et al. 2005). Other changes are more difficult to predict. Species will respond to changing climates individually; some species and some individuals will be more sensitive and vulnerable than others (Millar et al. 2006). Effects on forests could include expansion into alpine areas, increased loss of trees from insects, disease, windthrow, and/or fire, as well as changes in stream flow and vegetation and the animal species these habitats support; however, the degree of change is uncertain. If significant changes do occur over the next several decades, they may affect the range of wildlife, fish, and plant species in Southeast Alaska, as well as human use of these resources.

Cumulative effects on carbon sequestration depend on the amount of forest land harvested, the use to which harvested wood is put, how the non-NFS land is managed, on the amount of carbon released during harvest, processing, and transporting wood products, on-site decomposition, and factors such as the amount of new hydroelectric power (replacing diesel generated power), community expansion, and cruise ship emissions. It is likely that most of the state and private commercial forest land in Southeast Alaska, except for state parks and some other state lands, would be managed for the production of forest products under any of the alternatives considered in this analysis. The maximum amount of suitable land on the Tongass that is likely to be scheduled for harvest over the next 10 years would vary from nearly 18,000 acres under Alternative 1 to nearly 160,000 acres under Alternative 7. Higher levels of harvest would only occur if additional manufacturing facilities and markets are developed and on many other factors, such as funding and staff levels. If the products resulting from harvest are primarily lumber and other building materials, there is a potential that the carbon in these products would be stored for the life of the buildings, longer if the wood is recycled or placed in landfills. If the wood is used for paper products or fuel, carbon storage would be short term. Any temporary storage of carbon in lumber products may be completely off set by carbon released during and after harvest, transportation, and processing. Whether carbon sequestration would actually increase or decrease is unknown.

Additional research and monitoring is needed to effectively manage carbon in the forests of Southeast Alaska. In particular, information is needed on how changes in climate may affect plants, insects, and fungi in Southeast Alaska. Effects may include longer growing seasons due to warmer temperatures or shorter growing seasons due to dryer summer weather. Longer growing seasons and forest expansion into alpine areas may lead to additional carbon sequestration, though this may not always be the case. Carbon incorporated into needles, leaves, twigs, cones, and herbaceous plants that decompose quickly will not sequester much carbon (Millar et al. 2006). Carbon incorporated in the boles and main roots will be sequestered for at least the life of the tree. Climate change may result in changes in fire frequency and/or severity or may speed decomposition of dead material, either of which would release additional stored carbon. As information is gathered, adaptive management strategies can be developed to respond the environmental changes.

One monitoring effort that tracks changes in vegetation is the Forest Inventory and Analysis-Forest Health Monitoring (FIA FHM) program. The existing FIA plots containing lichen and vascular plant data could be combined with Tongass air quality biomonitoring plot data to develop air pollution and climate gradient models that predict changes in lichen communities and other vegetation due to projected climate change scenarios. Annual insect and disease surveys also provide information on how climate change may be affecting forests. Stream gauges, some of which provide long-term data on stream flow, are another tool. The Tongass will work with Pacific Northwest scientists to develop other monitoring measures to alert the Forest Service to trends that may affect the health of the Forest and the species that depend on it.

No significant cumulative effects on global carbon sequestration levels are expected under any of the alternatives considered in this analysis. Leighty et al. (2006) estimate that all the carbon stored in the forests of the Tongass represents approximately one quarter of 1 percent of the stored carbon in forests world wide. Carbon stored in forests, including forest soils, represent a small portion of total global carbon storage (terrestrial, ocean, atmospheric, and fossil carbon pools). For example, the oceans store approximately 20 times as much carbon as all terrestrial systems (IOC 2007). Therefore, it is reasonable to conclude that small changes in carbon sequestration on the Tongass, whether positive or negative, would have a minor effect on atmospheric carbon levels.

While there is general agreement among scientists that the climate is warming, there is considerable uncertainty concerning the exact effects of climate change on the forests of Southeast Alaska and how best to deal with possible changes to the many resources on the Tongass. There is a risk that climate change may result in increased blowdown, increased tree mortality from insects and disease, increased fire frequency and severity, adverse effects on air quality, changes to vegetation, streams, and fish and wildlife habitat, and, therefore, on subsistence and recreation.

The rate of decline and mortality of yellow-cedar in Southeast Alaska may be increased as a result of climate change. The snowpack in low-elevation areas may continue to be reduced as a result of the warming trend, resulting in greater exposure of fine roots to freezing, especially in the southern portion of the region (see *Forest Health* section).

The current warming trend may increase the number of severe windstorms, increasing the risk of catastrophic blowdown events. Juday et al. (1998) state that as of the date of their report, the increased frequency of storms in the last few decades has not corresponded to an increase in large-scale blowdown in Southeast Alaska and the 2006 Forest Health report noted very little blowdown in aerial and ground surveys (USDA Forest Service and ADNR 2007); however, this does not rule out the risk of increased windthrow in the future as additional warming occurs.

As noted above, climate models from both the Canadian Climate Center and the Hadley Center predict rising temperatures and a 10 percent decrease in summer precipitation in portions of Southeast Alaska. Both models also predict decreased soil moisture due to increased evaporation during warmer, drier summer weather. These factors may lead to an increase in fire frequency and severity. Both of these climate models predict an increase in the mean seasonal severity rating for fires in Southeast Alaska by 2060, ranging from 10 to 30 percent, depending on the model (Dale et al. 2001). Currently, fire is not a factor in the ecology of Southeast Alaska, and an increase of 30 percent would still result in very few fires. Given the high rainfall levels in Southeast Alaska (Ketchikan had only 2 days without rain in July 2006), a 10 percent decrease in summer rainfall would still result in wet conditions in most years. However, Southeast Alaska does occasionally experience drier conditions. For example, in July 1971 there were 23 days without rain. If warmer winter weather results in higher insect populations and increased tree defoliation (as discussed above), there is a risk that increased dead material and warmer, drier weather may spawn more fires than are normal for the area. As Berman et al. (1998) state, it is difficult to predict the magnitude of area likely to be burned in a region without an historic fire record, but they estimate that most fires would be small and of low intensity, suggesting a scenario in which 5,000 acres might burn over a period of decades (an average of approximately 100 acres per year). Juday et al. (1998) also suggest that the effects of fires on resources are likely to be low.

In addition to adversely affecting wildlife habitat and releasing additional carbon into the air, fires, either in Southeast Alaska or in neighboring British Columbia, could adversely affect air quality, as fires in western Canada did in 2004. Many scientists (Neilson 2007, Millar et al. 2006) recommend keeping forest density below full stocking to reduce stress on individual trees; this in turn may reduce insect and disease mortality, which may reduce fire risk and severity. Whether this strategy would be useful (or effective) in Southeast Alaska is uncertain.

Forest losses, either from insects, diseases, or fire, could harm wildlife habitat, which in turn could adversely affect subsistence resources. Conversely, Juday et al. (1998) suggest that warmer winters will result in sustained higher populations of Sitka black-tailed deer, one of the most important subsistence resources for residents of Southeast Alaska and a major prey species for wolves. Juday et al. (1998) also postulate that warmer, drier conditions could increase stream temperatures and cause seasonal low flows, both of which could adversely affect salmon. Berman et al. (1998) estimated that a 25 percent decline in salmon stocks would result in a loss of $25 million a year (approximately $31 million in current dollars). However, Oswood et al. 1992 state that melting glaciers would result in more runoff entering streams. This could offset any decrease in summer flows due to reduced summer precipitation, at least in the short run. In time, glacial mass would be reduced and their contribution to stream flow would decrease. Oswood et al. also believe that climate change would result in changes to the nutritional levels of leaf material entering streams, but could not predict whether this would have a positive or negative effect of fish.

In summary, general agreement exists that the climate is warming and indications are that summer precipitation may decline. However, there is considerable uncertainty surrounding specific predictions and even more uncertainty regarding the effect of these changes on the extent of fire, tree mortality, blowdown, air quality, fish and wildlife, subsistence, and recreation.

Geology, Karst, and Caves

Affected Environment

Geology

The Tongass National Forest is underlain by complex geology. Southeast Alaska is located near the boundary between the Pacific and North American tectonic plates. During the past 170 million years, tectonic movements have brought massive crustal blocks from across the Pacific Ocean and lodged and welded them onto the edge of the North American plate. The resulting southeast-northwest trending rock belts, or accreted terranes, include a wide variety of geologic materials (Nowacki et al. 2001). As the Pacific and North American plates collided, the coastal mountains of Southeast Alaska were uplifted. More recently, fault movements have offset the accreted terranes, adding further geologic complexity to the region. This tectonic plate boundary forms part of the "Ring of Fire," the area around the Pacific Ocean that is high in volcanic, mountain-building, and seismic activities. Evidence of relatively recent volcanic activity exists within the Tongass National Forest. The last certain activity of the Edgecumbe volcanic field occurred between 4 and 6 thousand years ago (Alaska Volcano Observatory 2006). Many volcanic features are also found on southwestern Suemez Island, including several surface flow types, obsidian sources, volcanic vents, and unique geomorphic features.

Together these tectonic, seismic, and volcanic forces have resulted in many different geologic formations in Southeast Alaska. Within the Tongass National Forest, generalized lithologies have been delineated and include granitics, noncarbonated sedimentary, carbonate sedimentary, metasedimentary, complex sedimentary and volcanics, volcanics, and mafics/ultramafics (Nowacki et al. 2001). During the past 12.5 million years, many of these lithologies have been affected by glaciers.

Within the Tongass National Forest, recurrent ice sheets formed and spilled from the St. Elias and Coast Mountains onto adjacent surfaces (Nowacki et al. 2001). Pushing seaward, these continental ice sheets combined with smaller alpine glaciers descended from isolated island peaks. Together, the ice sheets and glaciers reworked the topography of the land by rounding mountains, scouring bedrock, depositing glacial sediments, and carving U-shaped valleys and submarine trenches. In some areas, unconsolidated sediments were left, including glacial till (ice-contact deposits), glacial outwash, and glacial marine sediments. During the last glacial maximum, ice flowed all the way to the continental shelf. As glaciers retreated worldwide, the ice sheet receded first at coastal margins, then north and eastward along major channels and valleys into the mountains. Deglaciation was rapid and largely complete by 13,500 years ago.

The group of islands and fjords that currently make up the Tongass National Forest developed after the last major glacial retreat as seawater flooded the deeply incised valleys and trenches. Since deglaciation, coastlines have shifted dramatically due to tectonic events, worldwide sea level changes, and land rebound in the absence of the glaciers' massive weight. Elevated fossil-bearing marine beaches and deltas along the coastline indicate an uplift of the land relative to the sea since the last glacial maximum.

There are multiple sites with important vertebrate and invertebrate paleontological resources throughout the Tongass, including 220 million year-old sites on Gravina Island and the islands in Keku Strait (Baichtal 2006). Many important paleontological resources have been identified in caves on the Tongass National Forest.

As a result of the geological processes in Southeast Alaska, the region's physiography is topographically complex. Broad physiographic areas in the Tongass National Forest include icefields, recently deglaciated areas, large mainland river systems, angular mountains, rounded mountains, hills, lowlands, and recent volcanic fields. These distinct areas reflect the geomorphic and glacial history of the land. Continental ice sheets flowed, scoured, and deposited materials, tectonics added blocks of distinct geology, and volcanism superimposed younger rocks.

Karst and Caves

The geology and climate of Southeast Alaska are particularly favorable for karst development. Karst is a comprehensive term that applies to the unique topography, surface and subsurface drainage systems, and landforms that develop by the action of water on soluble rock (primarily limestone and marble [carbonates] in Southeast Alaska). The dissolution of the rock results in the development of internal drainage, producing sinking streams (streams that sink into the stream bed or karst features), closed depressions, sinkholes, collapsed channels, and caves.

Karst: A type of topography, drainage system, and landform that develops in areas underlain by soluble rocks, primarily limestone and marble (carbonates). About 3 percent of the land within the Tongass boundary is underlain by karst.

There are approximately 538,000 acres of very pure carbonates within the boundaries of the Tongass National Forest. This area includes carbonate bedrock on federal, state, and private lands. Approximately 458,000 acres of karst are on National Forest System (NFS) lands.

Because of fractures in the carbonates, high annual precipitation, and peatlands adjacent to the carbonate bedrock, karst has developed, to varying extents, within all carbonate blocks. The Tongass National Forest contains the largest known concentration of dissolution caves in Alaska.

In Southeast Alaska, the karst landscape can be characterized as an ecological unit found atop carbonate bedrock in which karst features and drainage systems have developed as a result of differential solution by surface and ground waters. These acidic waters are a direct product of abundant precipitation and passage of these waters through the organic-rich forest soil and adjacent peatlands. Recharge areas may be on carbonate or adjacent noncarbonate substrates. A few characteristics of this ecological unit include mature, well-developed spruce and hemlock forests along valley floors and lower slopes, increased productivity for plant and animal communities, extremely productive aquatic communities, well-developed subsurface drainage, and the underlying unique cave resources (Baichtal and Swanston 1996). The visible karst landscape also contains "epikarst," or surface features, particularly in the alpine and sub-alpine zones. These include deep shafts and fissures, eroded rills, and spires or spikes of limestone.

Karst lands add a vertical, underground dimension to land use planning. Karst subsurface drainage networks generally operate independently of, and with more complexity than, the surface drainage systems above, and the watershed characteristics of the surface may have little or no relationship to the subsurface system. On karst lands, the many solution-widened fissures at the surface become entry points into the subsurface drainage system, where water and sediment from surface sources move vertically downward into the underground lateral systems. Sediment and water from disturbed lands or roads may enter this system at a single point and emerge unexpectedly at one or more distant springs, sometimes crossing surface watershed boundaries. Karst groundwater systems routinely transport water for several thousands of feet to receiving caves, springs, and surface streams.

Most Tongass National Forest caves pre-date the most recent glaciation, as evidenced by the presence of glacial clays, glacial sediments, wood, Pleistocene vertebrate remains, and possibly ancient ice. Speleothems (i.e., secondary mineral deposits such as stalactites, stalagmites, flowstone, and crystal growths) from El Capitan Cave, on Prince of Wales Island, have been radiometrically dated to between 107,000 and 115,000 years old, or during the last interglacial period. Speleothem dates from other caves in the Tongass National Forest range from 53,000 to 185,800 years old. The most recent glaciation modified a pre-existing karst landscape, collapsing some passages and systems, gouging into others, and filling some with sediments. The epikarst (surface karst), which is well developed in higher elevations, has been removed in places at lower elevations by glaciation. Where low-elevation epikarst is present, primarily on the outer coast of islands seaward of Prince of Wales Island, vegetation has been re-established and a forested epikarst created. With the development of forested epikarst and peatlands, and the entrance of associated acidic waters into underground tributaries, a system of enlarged caves and vertical shafts has developed.

There is a definite tie between the karst landscape and the productivity of the spruce and hemlock forests found there. Dense stands of very large diameter spruce and hemlock at lower elevations are characteristic of many karst landscapes. The major contributors are believed to be the nutrient rich soils, well-developed subsurface drainage, and dissected bedrock surface, which allows the tree roots to hold fast and become more windfirm. The old-growth forest on this low-elevation karst provides a well structured, multi-layered canopy resulting in high-quality winter habitat for many wild species. The structure of the forest provides many forbs and shrubs, which provide forage. It is possible that this forage contains, at a minimum, higher calcium levels allowing for better bone, muscle, and antler development. The combination of quality forest structure and abundant nutritional browse make the karst landscape, in general, exceedingly important habitat.

Many wildlife species, including mammals, birds, and invertebrates, find the surface karst features and the stable environment and shelter provided within the caves to be valuable habitat (Baichtal and Swanston 1996). Cave systems provide critical summer and winter roosting and hibernating habitat for bats (Baichtal and Swanston 1996). Preliminary studies suggest that aquatic habitats associated with karst landscapes may be 8 to 10 times more productive than adjacent non-karst aquatic habitats (Baichtal and Swanston 1996). Karst aquatic habitats support a greater abundance, distribution, density, and variety of invertebrate species than non-carbonate habitats, have higher growth rates for smolts and resident fish, have less variable water temperatures and flow regimes, and contain unique habitat affecting species distribution, abundance, and adaptation.

The potential cultural and paleontological significance of the caves and karst landscape is high (Baichtal and Swanston 1996). The Pleistocene paleontology of the area is primarily known from cave and rock shelter deposits, which are often intimately related to archaeological sites. The cool, stable, non-acid environments in the caves result in exceptionally good preservation of bone and organic materials. To date, significant archaeological and paleontological materials have been discovered in over 30 caves and rock shelters within the Tongass National Forest. Evidence of human habitation, the oldest dating to nearly 9,730 years before present (BP), has been discovered in several caves on Prince of Wales and nearby seaward islands. Eighteen black bears (*Ursus americanus*), one dating to approximately 39,000 years BP, and 13 brown bears (*Ursus arctos*) ranging in age from 35,363 to 7,205 years BP and now extinct on Prince of Wales Island, have been found.

Of the 458,000 acres of NFS karst lands, approximately 303,000 acres were originally productive old growth (POG). Based on GIS queries, 95,000 of these POG acres (31 percent) have been harvested, leaving 208,000 acres of existing POG on NFS karst lands. Outside of NFS lands, approximately 77,000 acres of karst have been mapped, and about 26,000 of these acres were originally POG. At least half of these non-NFS POG acres on karst have been harvested.

Aerial and on-the-ground observations are revealing the effects of past resource management on karst systems. Hydrologic evidence suggests that timber harvest increases the amount and changes the timing of peak surface flow, resulting in accelerated sediment and debris transport. Passages have flooded, which had not flooded for centuries, and many cave entrances were infilled and/or blocked by logging slash, sediment, and debris, resulting in surface flows being rerouted into different passages. In the past, runoff generated from road surfaces commonly was diverted into karst features. It is not yet fully known what cumulative effects past timber harvest have had on the epikarst landscape. In some portions of the Tongass National Forest, 70 to 80 percent of the commercial forest land within specific karst blocks has been harvested. Overall, 38 percent of original POG on karst lands below 800 feet in elevation have been harvested on the Tongass. In the North Central Prince of Wales Biogeographic Province (which includes most of Thorne Bay Ranger District and part of the Craig Ranger District), 51 percent of the original POG on karst lands below 800 feet have been harvested.

One of the five additional “emphasis areas” identified during the 1997 Tongass Forest Plan Revision was karst and cave resource management. Responding to the need for a management strategy, standards and guidelines were developed that provided for other land uses while taking into account the function and biological significance of the karst and cave resources within the landscape. This strategy was developed during the 4 years prior to completion of the 1997 Tongass Forest Plan, beginning with the recommendations of a karst and cave resource significance assessment completed by Aley et al. (1993, as cited in USDA Forest Service 1997a) and combining the most current thinking on karst management issues. The Forest began adopting a land management strategy for the karst lands similar to “hazard area mapping” or “risk assessment.” Referred to as “vulnerability mapping” or “karst vulnerability,” this strategy assesses the susceptibility of the karst resources to any land use. Vulnerability mapping utilizes the fact that some parts of a karst landscape are more sensitive than others to planned land uses. The key elements of the strategy focus on the openness of the karst system and its ability to transport water, nutrients, soil and debris, and pollutants into the underlying hydrologic systems. The strategy strives to maintain the capability of the karst landscape to regenerate a forest after harvest, to maintain the quality of the waters issuing from the karst hydrologic systems, and to protect the many resource values within the underlying cave systems as per the requirements of the Federal Cave Resources Protection Act (FCRPA).

On the low to moderate vulnerability karst lands (defined in the Karst and Cave Resources Standards and Guidelines of Chapter 4 in the Forest Plan), where mineral or glacially derived soils fully or partially cover the epikarst, forest regeneration is exceptional. In these areas, even the complete loss of soil and litter from the surface of the limestone will not prohibit the re-establishment of a forest because the displaced surface materials are retained within the epikarst channels (Harding and Ford 1993, as cited in USDA Forest Service 1997a). On highly sensitive karst lands, the epikarst channels are too deep to allow conifer seedlings to establish themselves even if the displaced soil is retained. The bottom of the channels may also be open, directly transporting sediment and debris into the karst groundwater system. Highly sensitive or vulnerable karst areas are generally found at higher elevations, have thin organic soils that are easily displaced, are on steeper slopes, or are in areas of intense karst development. Previous harvest in such areas has increased the percentage of bare rock, resulting in less-than-desirable forest regeneration.

Recent implementation and effectiveness monitoring (USDA Forest Service 2004a) found that the Karst and Cave Standards and Guidelines outlined in Forest Plan were being implemented to the fullest extent practicable. Karst resource input was provided for a number of sales, including those on the Thorne Bay Ranger District, where forested karst lands are most extensive.

Although most caves found to date on the Tongass are not suitable for recreation purposes because of frequent flooding, instability, or presence of fragile structures, the Forest Service is seeking opportunities for surface and subsurface public access and interpretation.

Karst areas in Southeast Alaska are most comparable to those of karst lands found on Vancouver Island and the Queen Charlotte Islands of British Columbia (Canada), portions of Patagonia (Chile), Tasmania, and the west coast of the South Island of New Zealand. All of these areas have very steep surface slopes and subsurface hydraulic gradients, and very high levels of rainfall. These characteristics put them among the most dynamic karst terrains on earth, evolving and changing more rapidly and abruptly than karst in more moderate settings. The Karst Panel Report (Aley et al. 1993, as cited in USDA Forest Service 1997a) found the karst lands of the Tongass National Forest to be of national and international significance for a variety of reasons. The Karst Review Panel in the summer of 2002 confirmed these findings (Griffiths et al. 2002). Both of these panels consisted of world renowned karst experts with a breadth of karst resource backgrounds and a wide variety of international exposure to karst areas and management considerations. Not only is the level of karst development and the karst hydrology and mineralogy globally significant, the paleontological and archaeological discoveries have provided information on the prehistory of Southeastern Alaska and contributed to and challenged theories of the peopling of North America.

The natives and local inhabitants of Southeast Alaska have long known of the presence of caves. The existence of well-developed cave systems was first reported in 1975 and mapping of the caves began in 1987. The existence of vast areas in which karst had developed was fully recognized in 1990. Though noted by early foresters and geologists, the relationship between high site productivity and the presence of karst landscape became apparent at about this same time. With the passing of the FCRPA in 1988, the Forest struggled with methods to protect the many caves throughout the landscape. At first, protection focused on the large, significant karst features and cave entrances. Subsequent measures tended to look at entire karst hydrologic systems.

As of 2006, the Tongass inventory includes 611 caves (plus one state cave). Of these, 290 were listed in 1996 during the initial process of identifying significant cave resources. An additional 87 caves were added in 2003. The Tongass National Forest has received another 57 nominations that are pending. The remaining 177 caves do not have nominations. Intense karst development has been identified on northern, central, and south-central Prince of Wales Island, Kosciusko Island, Dall Island, Heceta Island, Revillagigedo Island, and on the mainland southeast of Wrangell (Baichtal 2006).

Approaches to characterizing karst areas on the Tongass National Forest in recent years have included tracer dye studies to define karst watersheds and water quality parameters, physical monitoring of karst springs, and measurement of rainfall (USDA Forest Service 2004a). These efforts provided preliminary data on how karst groundwater systems and water chemistry relates to precipitation and runoff. These data will be used to establish baseline conditions, and will be compared with karst conditions monitored after implementation of management activities. In addition, Light Distancing and Ranging (LiDAR) technology has been used in ongoing inventories of karst and cave resources.

Environmental Consequences

Geology

Updates to the Forest Plan standards and guidelines would apply under all alternatives except the Alternative 5 (No Action). The standards and guidelines related to geology would be updated under the proposed Forest Plan. The focus of the revisions would be to identify and find solutions to management problems related to geologic resources, and to develop geologic resources on the Tongass National Forest. Geologic inventories would be conducted to cover bedrock geology, surficial geology, stratigraphy, hydrogeology, geomorphic features, geological hazards, karst features, caves, and paleontology, including potential for geologic formations to yield fossil resources of scientific and other values. The focus on geologic resources could result in greater protection of unique features and greater utilization of geological resources. Refer to the *Minerals* section for more information on potential effects related to mining and mineral resources.

Karst and Caves

Karst lands have separate issues and concerns compared with other landforms because karst is a three-dimensional landform with closely integrated surface and subsurface processes. Groundwater flows relatively slowly through porous rock and soil, or via fracture flow, in non-karst terrain. In karst terrain, groundwater may flow relatively quickly through complex underground systems of solution-widened conduits that vary from fissures a few inches wide to cave systems many feet wide. Potential effects to karst systems and caves and associated drainages from timber harvest and road building include changes in hydrology, infiltration rates, sediment production, debris transport, pollutants, and introduction of organics that can lead to oxygen depletion. Issues and concerns related to karst lands primarily revolve around potential changes to groundwater flow in the underground system. Any management activity that causes sediment or organic debris to build up in the subsurface conduits decreases the capacity of these conduits and makes the formation of surface streams more likely. Similarly, any management activity that increases groundwater recharge may also affect the capacity of the conduits in the underground system and make formation of surface streams more likely. Changes in the presence of surface water can produce broad ecosystem changes both above and below ground. Groundwater recharge in karst lands occurs by either discrete or diffuse recharge. Discrete recharge refers to losing or sinking streams that enter the subsurface at specific insurgence points. Diffuse recharge refers to subsurface entry of water through the forest floor and the epikarst. Losing or sinking streams can rapidly deliver sediment into subsurface passageways.

Sediment transport into karst systems also produces concern. This concern is primarily attributed to the size of past harvest blocks and the rate at which the landscape was harvested prior to the early 1990s, when the extensiveness and significance of karst terrain on the Tongass National Forest became more fully recognized. The current standards and guidelines address these concerns to a high degree.

Potential effects on karst lands from planned timber harvesting, associated road construction, and quarry development may occur; however, with careful implementation of the current or proposed standards and guidelines (as modified through ongoing monitoring and adaptive management), and site-specific mitigation measures (designed and implemented at the project level), the Forest expects to mitigate the effects of any proposed activity. Site-specific mitigation measures include protection of the high vulnerability karst areas and features, partial cutting, reduced harvest unit size, use of logging systems that achieve at least partial suspension, reductions in rate of harvest, and other changes in logging practices.

The Karst Review Panel in the summer of 2002 found that implementation of the Karst and Cave Standards and Guidelines from the current Forest Plan had ensured a high level of protection for karst resources overall (Griffiths et al. 2002). The Panel noted high standards in both the philosophy of management and the way that specific management practices were formulated and applied. Implementation of specific policies and procedures was found to be very good and in general compliance with the stated goals and objectives of the karst program. The Panel also noted the extent to which high vulnerability karst had been protected since 1997. In addition, the Panel outlined the action required to more actively manage karst landscapes covered with second-growth stands and recommended a new procedure for assessing the autogenic (precipitation on carbonate rocks) recharge component of karst units.

Implementation and effectiveness monitoring of these karst and cave standards have brought to light a few discrepancies (USDA Forest Service 2004a). Specifically, the definition of low, moderate, and high vulnerability karst lands; the application of appropriate mitigation; the approach to catchment area management; and the resolution of conflicts with riparian management standards have surfaced as topics that need clarification. These have been addressed in the proposed Forest Plan, as discussed below. In addition, continued training and involvement of karst specialists, hydrologists, soil scientists, and other resource specialists has been identified as essential to implementing the standards and guidelines.

Several elements of the Karst and Cave Standards and Guidelines would be updated under the proposed Forest Plan as part of all alternatives except Alternative 5 (No Action). Most importantly, the issues identified as unclear in the current Forest Plan would be clarified, as described with the following explanations. The four-step process to complete a karst landscape assessment would be described in detail, including specific guidance for determining low, moderate, and high vulnerability karst. Depending on level of vulnerability, some management activities would be restricted on karst lands, and mitigation measures would be specified. Catchment areas would be explained, including allogenic (precipitation on non-carbonate rocks) and autogenic (precipitation on carbonate rocks) recharge areas. The potential effects related to second growth management (including commercial thinning), salvage of windthrown timber, and mineral development on karst lands would be addressed, and restrictions detailed based on the level of karst land vulnerability. The proposed standards and guidelines would provide detailed descriptions of factors to evaluate implementing management activities on or near karst lands; however, they also would allow flexibility depending on the professional judgment of karst-trained specialists.

The Karst Review Panel in the summer of 2002 found that implementation of the Karst and Cave Standards and Guidelines from the current Forest Plan had ensured a high level of protection for karst resources overall (Griffiths et al. 2002). The Panel suggested the proposed changes to define appropriate resource management activities in areas of karst management that were unclear in the current version of the Forest Plan. The action alternatives (Alternatives 1, 2, 3, 4, 6, and 7) would incorporate some of these changes in revised standards and guidelines and through proposed designation of new geologic Special Interest Areas. These new Special Interest Areas include all identified high vulnerability karst lands that are not already protected within non-development Land Use Designations (LUDs). Refer to the *Other Special Land Use Designations* section for more information. Significant effects to karst lands and caves have been avoided during implementation of the current Forest Plan. The proposed changes would likely protect karst lands and caves to an even greater extent.

Much of the karst land within development LUDs has been designated as high vulnerability karst land and is protected by standards and guidelines or included within geologic Special Interest Areas. It is estimated that 30 percent of the other karst lands will be determined to be high vulnerability karst with ground verification in the future.

Approximately 457,765 acres of karst underlies NFS lands inside the Tongass National Forest. Under Alternative 5 (No Action), the estimated maximum future harvest on NFS karst lands would be approximately 76,459 acres, including POG and young growth on suitable karst lands (Table 3.2-1). Alternative 6 would involve slightly less area, and Alternatives 1, 2, and 3 would include fewer areas of estimated maximum future harvest on karst lands. Alternatives 4 and 7 would include the most area of karst lands open for timber harvest activities (Table 3.2-1). Based on the current Forest Plan and proposed changes, karst inventories and vulnerability assessments would be required before timber harvest could occur on suitable lands.

Table 3.2-1
Estimated Maximum Future Tongass Harvest on Karst Lands under the Alternatives

Alternative	Old Growth on Karst Lands (acres)	Young Growth on Karst Lands (acres)	Total Area (acres)
Alternative 1	11,941	17,198	29,140
Alternative 2	17,745	42,737	60,482
Alternative 3	19,813	46,358	66,170
Alternative 4	32,512	53,310	85,822
Alternative 5	24,946	51,513	76,459
Alternative 6	22,549	50,079	72,628
Alternative 7	44,121	59,287	103,408

No additional harvest is anticipated in any areas mapped as high vulnerability karst under any of the alternatives. These areas are included in the 42,873 acres of Special Interest Areas under Alternatives 1, 2, 3, 4, 6, and 7, and are not suitable for harvest under Alternative 5. The estimated maximum amount of future POG harvest that could occur on NFS karst lands would vary by alternative, ranging from 11,941 acres under Alternative 1 to 44,121 acres under Alternative 7 (Table 3.2-1).

The maximum amount of construction of new roads on karst lands would also vary by alternative, ranging from 115 miles under Alternative 1 to 329 miles under Alternative 7 (Table 3.2-2). The percentage of new roads that would be constructed on karst lands ranges from 5 or 6 percent under Alternatives 4, 5, 6, and 7 to 15 percent under Alternative 1, where fewer roads would be constructed but a larger percentage of them would be constructed on karst lands. Of these proposed new roads on karst lands, from 1 to 2 miles would occur on slopes greater than 67 percent (Table 3.2-2).

Table 3.2-2
Estimated Maximum New Road Construction on Karst Lands under the Alternatives

New Roads on Karst Lands	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Alt. 5	Alt. 6	Alt. 7
Length of New Roads on Karst Lands (miles)	115	183	194	259	216	206	329
Percent of New Roads on Karst Lands	15%	9%	7%	5%	6%	5%	6%
Length of New Roads on Slopes >67% on Karst Lands (miles)	1	2	2	2	2	2	2

Cumulative Effects

There are approximately 537,588 acres (840 square miles) of karst lands within the boundaries of the Tongass National Forest. Approximately 457,765 acres (715 square miles) are on NFS lands. Of this, approximately 247,680 acres (387 square miles) are protected in Wilderness, LUD II, or other non-development LUDs under the current Forest Plan. The remaining high vulnerability karst on NFS lands are protected by standards and guidelines that include substantial no-harvest buffers.

Past timber harvest has affected the epikarst landscape on the Tongass National Forest. In some portions of the Tongass, 70 to 80 percent of the commercial forest land within specific karst blocks has been harvested. It is estimated that about 21 percent (95,479 acres) of the karst lands on NFS lands have been harvested (based on the GIS database). Approximately 133 square miles of karst land have been harvested on Prince of Wales Island alone. In addition, 575 miles of authorized or system roads have been mapped on karst lands (out of 3,532 total authorized road miles). These 575 miles include 116 miles at Maintenance Level 1 (closed), 338 miles at Maintenance Level 2 (for high-clearance off-road vehicles), and 112 miles at Maintenance Levels 3, 4, and 5 (the highest maintenance levels, maintained for passenger vehicles). It is likely that a few hundred miles of unauthorized roads also exist on karst terrain. Of the 575 miles of roads mapped on karst lands, 87 percent occur on slopes of less than 35 percent, 13 percent occur on slopes of between 35 and 67 percent, and less than 1 percent occur on slopes of greater than 67 percent.

Baichtal and Swanston (1996) observed sediment deposits and waterline marks in underground systems that suggested that past timber harvesting had increased sediment and debris transport and flooding of underground passages, many of which had not previously flooded for centuries. These timber harvests were conducted prior to the Karst and Cave Resources Standards and Guidelines implemented in the 1997 Forest Plan. As a result, they had more significant effects on karst lands than current and future harvest activities. At that time, many cave entrances were filled or blocked by logging slash, sediment, and debris. Additional runoff generated from road surfaces commonly had been diverted into karst features. They also noted strong evidence of greatly increased surface runoff on karst landscapes and adjacent surfaces after timber harvest, which increased sediment, nutrient, and debris transport capability of associated drainage networks.

Based on information from Prince Wales Island, Baichtal and Swanston (1996) noted few tree regeneration problems in low-elevation stands on karst landscapes. As a consequence, most easily accessible, low-elevation karst areas on the island had been harvested. After the initial timber harvests, harvest activities concentrated on steeper, higher elevation karst landscapes characterized by shallower, excessively well-drained soils. Baichtal and Swanston (1996) suggested that trees were smaller and regeneration problems were greater at these steep, upper elevation sites. This condition possibly resulted from shallow soils with low nutrient availability, excessive drainage of surface and soil waters into subsurface karst systems, removal of much of the shallow soil because of inadequate log suspension, and continued desiccation of the soil once the protective forest canopy was removed. After timber removal, high rainfall rapidly transported fragile soils into the well-developed epikarst.

More recent monitoring of karst lands near harvested areas (USDA Forest Service 2004a) have confirmed that current timber harvest practices have adjusted substantially to accommodate Karst and Cave Standards and Guidelines. For example, karst resource input was provided for timber sales projects throughout the Tongass.

Extensive landscape changes and ground disturbance have occurred and are likely to continue to occur on non-federal lands in Southeast Alaska. These include timber harvest and road construction, mining, recreation and tourism, growth of human settlements, transportation projects, and energy and transmission projects. Forest Service regulations requiring protection of karst resources do not apply to non-federal lands. Approximately 88,000 of the nearly 538,000 acres of karst lands within the Tongass National Forest boundary are on state or private lands. Assuming that none of the karst on state or private lands is protected, an estimated 69 to 74 percent of all the karst lands in Southeast Alaska would be protected in non-development LUD areas under the alternatives.

Transfers of karst lands from NFS lands to other land managers or private owners could also occur under any of the alternatives through land exchanges or other types of land adjustments (see the *Lands* section and Appendix C to the Final EIS). The karst forest lands on Prince of Wales and neighboring islands are among the candidate lands that have been discussed in the past. This type of future action could increase the amount of karst lands in Southeast Alaska that are not in a protected LUD. Any exchange or other type of adjustment (outside of legally required conveyances) would require NEPA analysis, most likely an EIS, which would include public involvement and would disclose any adverse effects to karst and cave resources, as well as to other resources.

Soils

Affected Environment

Soils in Southeast Alaska develop in parent materials originating from a variety of geological or vegetative sources. Parent material is the inorganic or organic matter in which soils develop, and in the Tongass National Forest includes volcanic ash; glacial deposits; hillslope, stream, and uplifted marine sediments; rock; and deposits of decomposed plant materials. Soils are commonly divided on the basis of their parent material. Both mineral and organic soils occur extensively within the Tongass National Forest, where more than 100 different soils have been identified. Soils cover 84 percent of the inventoried land surface area of the Tongass; the remainder consists of ice, exposed bedrock, and bodies of water.

From a resource management perspective, soil productivity (i.e., a soil's ability to support vegetative growth) and the potential loss of soils or off-site effects from erosion and landslides are the principle concerns. The productivity of soils directly or indirectly affects the productivity of other forest resources. Tree growth, wildlife and fish habitat quality, and recreation uses and potentials depend in part on the quality of soils. In Southeast Alaska, soil productivity, in terms of tree growth, is high on well-drained soils (e.g., on steep slopes and in karst areas) and decreases as latitude and elevation increase and as drainage becomes poorer.

Soil, or site, productivity is generally measured by the rate of biomass accumulation, and site index is commonly used to give a relative indication of this productivity. Site index is determined by the height of dominant trees at a specified age. The site index tables or curves available for use in Southeast Alaska were developed from trees in even-aged stands, not the uneven-aged or old-growth stands that predominate here; consequently, the resulting site index categories are more useful for comparison than as absolute numbers. Soil productivity also can be estimated from the characteristics of individual soil types. The principal characteristics are soil depth, drainage, acidity, and coarse fragment content. Over one-quarter of the total productive forest land in the Tongass National Forest has been mapped in the highest site index category (Category 4), which means that on average these sites will grow trees greater than 80 feet tall in 50 years (Table 3.3-1). Less than 10 percent of the Tongass falls into the lowest site index category (Category 1), which corresponds with trees less than 40 feet high in 50 years. Almost one-quarter of the productive old growth (POG) and two-thirds of the harvested young growth have been mapped as Category 4 (Table 3.3-1).

Table 3.3-1
Estimated Percent of the Productive Forestland on the Tongass by Site Index Category

Productive Forest Land Category	Site Index Category 1: Avg. Site Index = 0-40	2: Avg. Site Index = 41-60	3: Avg. Site Index = 61-80	4: Avg. Site Index > 80	Unmapped[1]	Total
Productive Old Growth	9%	14%	23%	24%	29%	**100%**
Young Growth – Harvested	4%	6%	21%	66%	2%	**100%**
Young Growth – Natural	13%	6%	16%	39%	26%	**100%**
Total Productive Forest land	9%	13%	23%	28%	26%	**100%**

[1] Unmapped areas are mostly in Wilderness or National Monument.

Soil erosion in the form of gully, sheet, and rill erosion is a minor occurrence under natural, undisturbed conditions in Southeast Alaska, because the thick surface duff layers that cover the mineral soils protect them from surface erosion. Mineral soils can be disturbed and exposed either by natural causes, such as landslides and blowdown, or management activities, such as timber harvest and road construction. Surface erosion can become active once the duff layer is removed and can remain active until revegetation occurs.

Landslides, both naturally occurring and human-caused, dominate soil movement processes on steep forest lands in Southeast Alaska (Swanston 1969, 1974). Although conducted more than 30 years ago, Swanston's papers present excellent characterizations of landslides in Southeast Alaska. Landslides deliver eroded material to streams more quickly, and in greater quantity, than surface erosion. Landslides can seriously retard soil productivity for forest regeneration on slopes by removing the soil mantle down to bedrock or glacial till. It can take 50 to 100 years for soil layers to be rebuilt on exposed bedrock in these landslide areas. Debris deposited on lower slopes and valley bottoms may improve site productivity locally because of incorporation of organic nutrients and improved drainage. Regeneration at such sites is rapid.

In the Tongass National Forest, several factors control soil stability on steep terrain. On steep forested slopes, the dominant failure type is debris avalanche (the failure of a finite mass of water-charged overburden material along a relatively flat surface). These landslides occur primarily at shallow depths (1 to 3 feet) in the soil overburden. The texture of the soil overburden is characteristically gravelly silt or gravelly silty sand; less commonly the texture might be sandy gravel (Swanston 1997). The dominant steep-slope soil types with these textural characteristics in Southeast Alaska have little or no cohesion. Organic content may exceed 30 percent locally because of the downward migration of organic particles into the mineral soil zone, which substantially increases cohesion at some sites. A qualitative system of indexing mass failure provides an indication of the relative frequency of mass failures when vegetation is cleared or the land is disturbed.

Approximately half of the Tongass is made up of lands with slopes less than 35 percent (Table 3.3-2). Approximately one-third of the Tongass ranges in slope from 35 to 67 percent, and the remaining 18 percent exceeds 67 percent slope. Only 13 and 3 percent of POG and harvested young growth exceed 67 percent slope, respectively. In general, these steep slopes pose greater risks for soil erosion through landslides.

Table 3.3-2
Estimated Percent of the Tongass National Forest, POG, and Young Growth by Slope Category

		Percent Slope Category			
	Acres	**0-35%**	**35-67%**	**>67%**	**Total**
Productive Old Growth	4,951,154	49%	38%	13%	**100%**
Young Growth – Harvested	454,725	68%	29%	3%	**100%**
Young Growth – Natural	233,844	81%	14%	4%	**100%**
Other Areas	11,134,085	49%	30%	22%	**100%**
Tongass National Forest	16,773,808	50%	32%	18%	**100%**

Landslides are thought to be an important natural process by which fish habitat structures and stream substrates are replenished (Meehan 1991, Reeves et al.1995, Wing 2000). Sediments and large woody debris, including gravels, are deposited in stream headwater areas. During high flow periods, some of that sediment and wood is transported through the stream system, although much wood may be stored in headwater channels. A recent study by Martin and Benda (2001) in the Game Creek Watershed found that only about 1 percent of the wood (by volume) from landslides reaches mainstem fish habitat. The wood is typically entrained in the upper reaches of fish habitat on alluvial fans and in transition channels. Sediments may more commonly flush through the stream system. Settled gravel can provide fish spawning habitat. Large wood that does reach mainstem aquatic habitat forms structures for hiding and resting. The frequency of delivery and quantity of the material delivered will determine the effect (either positive or negative) landslides will have on stream channels and fish habitat (Meehan 1991, Reeves et al. 1995, Wing 2000). It is generally thought that increased frequency of slides and quantity of material delivered, above the natural range of occurrence, moves the streams out of equilibrium and degrades fish habitat (Meehan 1991, Reeves et al. 1995, Wing 2000).

One inventory of landslides that occurred between 1963 and 1983 in Southeast Alaska (Swanston and Marion 1991) showed that roughly 10 percent (118) of the landslides occurred in clearcut harvest areas or were directly associated with timber harvesting, whereas roughly 90 percent (1,277) occurred in unlogged areas. On a per-acre basis, however, landslides occurred in clearcut areas about three times as frequently as in unlogged areas. Landslides in unlogged areas appear to be larger and longer than those in logged areas. Of the 1,277 landslides that occurred on unlogged areas, 37 affected fish streams (3 percent), while 7 of the 118 landslides on logged areas affected fish streams (6 percent). It is important to note that clearcut timber harvests conducted between 1963 and 1983 did not include the restrictions that were implemented during the past 15 years or would be implemented in the future. These harvests often involved logging large portions of watersheds with very large clearcuts and almost no buffers, slope restrictions, or other restrictions. One would expect to find more landslides after these earlier clearcuts than after the types of clearcuts expected under the current Forest Plan.

The Soil and Water Standards and Guidelines in the current Forest Plan are important for minimizing potential detrimental soil disturbance. According to results of 2004 soil and water implementation and effectiveness monitoring (USDA Forest Service 2004b), the Tongass National Forest is implementing the standards and guidelines for soil disturbance successfully during timber sale administration and road construction. Data collected on Prince of Wales Island and on the Wrangell and Petersburg Ranger Districts indicate that all timber harvest units, including cable, helicopter, and shovel yarding systems, are within the established Region 10 soil quality guideline of less than 15 percent soil disturbance that is considered potentially detrimental (as set forth in Forest Service Manual 2554).

The current Forest Plan takes a relatively conservative approach to avoid potential effects on soil resources. Seven specific items are listed in the proposed Forest Plan to ensure that land use activities avoid irreversible or serious and adverse effects on soil resources. These are based on research on the effects of management activities on soils in Southeast Alaska. For example, at the Forest Plan level, slope gradients of 72 percent or more are removed from the tentatively suitable timber base because of the high risk of soil mass movement and accelerated erosion of Class IV channel systems (see the *Water* section for more information regarding channel classes). At the project planning level, the Forest Supervisor or District Ranger may approve timber harvest on slopes of 72 percent or more on a case-by-case basis, after on-site analysis of slope and Class IV channel stability and an assessment of potential impacts of accelerated erosion on downslope and downstream fish habitat, other beneficial uses of water, and other resources. The threshold of 72 percent comes from the applicable research conducted in Southeast Alaska (Swanston 1997).

As another example, the effectiveness of standards and guidelines related to yarding methods were monitored in Landwehr (1993). This study involved 199 soil disturbance transects in timber harvest units on the Thorne Bay Ranger District. Mineral soil disturbance on individual transects averaged 4.6 percent. Shovel yarding averaged slightly higher levels of disturbance, 5.1 percent, as compared to cable yarding systems that averaged 4.0 percent. In the Coffman Cove area, where operators were less experienced, shovel yarding averaged 7.1 percent mineral soil disturbance. After operators in the Coffman Cove area were directed to reduce soil disturbance, conditions improved and total disturbance was reduced. Standards and guidelines for overall mineral soil disturbance were met in all the units involved in the study.

A Forest-wide inventory to identify, delineate, and digitize all landslides was initiated in 2001. Landslides are being digitized as an independent layer in GIS. As of 2004, landslide inventories have been completed for approximately 2.9 million acres of the Ketchikan, Petersburg, Sitka, and Wrangell Ranger Districts. Additional landslide inventories are being conducted. To date, the density of landslides is greater in managed stands than in unmanaged areas, which is consistent with the results of the Swanston and Marion (1991) inventory. However, the majority of past harvest activities were conducted under substantially lower protections than current-day harvest activities (see the subsection titled *Past Old-Growth Harvest* in the *Affected Environment* portion of the *Biodiversity* section). Continued emphasis is necessary during timber harvests to implement measures that minimize mass failures and landslides.

Environmental Consequences

Direct and Indirect Effects

Forest management activities can cause soil erosion and subsequent loss of site productivity through the exposure of mineral soil, alteration of subsurface drainage, and the concentration of soil and rock material at unstable sites. The management activities that have the greatest potential to affect soil erosion, including sheet, rill, gully, or mass movement erosion, are timber harvest-associated activities, such as road and log-landing construction, rock pit development, and some yarding methods. Forest-wide standards and guidelines protect all areas of the Forest to a high degree, as indicated by 2004 soil and water implementation and effectiveness monitoring (USDA Forest Service 2004b). Monitoring indicates that the Region 10 soil quality standard of less than 15 percent soil disturbance was achieved during timber harvest activities. Soil erosion and loss of productivity would be expected to be even lower if lands are converted from development LUDs to non-development LUDs, which prohibit timber harvest and most road construction.

Due to the substantial amount of vegetative groundcover remaining on harvest units during and following timber harvest, surface erosion from these areas is usually small (Martin and Kirtland 1995, Swanston 1969). The larger effect of harvest activities on soil erosion occurs as landslides. More than 300 landslides and debris flows were triggered by an October 1993 storm on basin-scale clearcuts on Prince of Wales Island (Johnson et al. 2000). Eroded soil from these landslides was transported as sediment in nearby channels. Channel bedload sediment after the 1993 events was 2 to 10 times greater and relatively finer compared with bedload transport in a channel that had last experienced a landslide and debris flow in 1961 (Gomi et al. 2004). Swanston and Marion (1991) mapped landslides in the Tongass National Forest during the 21-year period, 1963 through 1983. They noted an occurrence rate of 118 landslides per 980 square kilometers (242,163 acres) in harvested or roaded areas over 21 years. Based on this count, an average of one landslide occurred per 2,052 acres of harvest over 21 years, or one landslide per 43,092 acres (on average) per year. They found that landslides were 3.5 times more likely on harvested areas. A more recent study (Johnson et al. 2007) compared the effects from 100 percent tree removal to partial cuts (25, 50, and 75 percent removals). They focused on effects to soil saturation (groundwater levels) and found increasing soil saturation with increasing percent tree removal. Increased soil saturation likely correlates with increased potential for soil erosion through landsliding, although they did not model this possibility directly because of uncertainties in estimating loss of cohesion as a result of changes in root strength in partial cuts.

The effects of timber harvest on soil productivity are described in several papers in Slaughter and Gasborro 1988. Regeneration after clearcutting is excellent on all but a few sites in coastal Alaska, and, once established, growth rates of hemlock and spruce are relatively high (Farr and Ford, in Slaughter and Gasborro 1988). New stands contain several thousand stems per acre, and crown closure begins to take place by age 15 to 20 years. Crown closure approaches 100 percent by 25 to 30 years of age and remains so for 100 years or more. Silen (in Slaughter and Gasborro 1988) also states that more than 90 percent of clearcut areas densely restock naturally in Southeast Alaska. Precommercial thinnings aid in achieving desired stocking levels and increased growth (Pawuk, in Slaughter and Gasborro 1988). Klock (in Slaughter and Gasborro 1988) notes that soil compaction, most frequently by ground skidding operations, leads to reduced timber volume growth. The current and proposed Forest Plan includes standards and guidelines to avoid these effects.

Blowdown, or windthrow, can increase along the edges of regeneration harvest units, and this may expose mineral soil. Blowdown increases the potential for soil erosion and may increase the potential for landslides. According to a study by Kramer (2001), watersheds in the Tongass National Forest that experience more intense soil mixing from windthrow have lower levels of strongly humified soil carbon pools (e.g., lower levels of reprecipitated acid) than areas that have not experienced windthrow. The disturbed watersheds include more organic matter in a partially decomposed particulate form, which translates to less acidic carbon forms, higher ion exchange capacity, higher soil pH, and lower bulk density in the soil (Kramer et al. 2004). The disturbed soils are more aerated, better drained, and have higher nutrient status.

Soil productivity decreases from the construction of roads because land is taken "out of production" (i.e., removed, covered over, or compacted). Erosion increases from the construction of roads because of the destabilizing effect of cuts, fills, and drainage alterations, and the lack of protective vegetation cover on road surfaces and other disturbed areas.

The amount of road construction by alternative is used as a measure of both soil productivity losses and erosion potential. In one attempt to quantify road erosion, Kahklen and Hartsog (1999) developed a multiple regression analysis based on road erosion studies in the Tongass National Forest. They found that road erosion was highly variable. The primary variables that correlated with greater sediment yields were heavier traffic volumes, more rainfall, higher road gradients, and lack of road resurfacing. These and other site-specific variables are evaluated more precisely during project planning, based on the specific conditions found at the project site, and will vary based on soil parent materials, rock durability, slope, location within a watershed, mass movement hazard, and other factors. Paustian (1987) measured short-term effects of road building on soil erosion in the Kadashan watershed that resulted in increased suspended sediment yield equivalent to 2 percent of the estimated annual sediment yields. Potential increases in total estimated sediment yield over a 2-year post-road construction period ranged from 20 to 66 percent in three Kadashan study streams. Montgomery (1994) found that drainage concentration from ridgetop roads caused both landsliding and integration of the channel and road networks. Road drainage concentration increased the effective length of the channel network and strongly influenced the distribution of erosional processes in Southeast Alaska.

Standards and guidelines, Best Management Practices (BMPs), and other relevant mitigation measures are applied at the project level to minimize potential adverse effects. At the Forest Plan level, the overall difference in acres disturbed by roads is a good indication of how site-specific effects are likely to vary between alternatives. Refer to the *Water* and *Fish* sections for more detailed analyses of potential effects related due to roads. Table 3.3-3 displays the maximum acres to be covered by road surfaces after the first 15 years of Forest Plan implementation. In addition, it presents the cumulative acres of road surfaces—the total amount of land area covered by all roads after 100+ years - full implementation of the Forest Plan (assuming none of the roads is completely obliterated).

Under all but Alternatives 4 and 7, the cumulative acres of road surfaces would be equal to or less than expected under the current Forest Plan. The cumulative acres of road surfaces would be smallest under Alternatives 1, 2, and 3. Reductions in soil productivity losses and soil erosion would correlate with smaller cumulative roaded acres.

Table 3.3-3
Estimated Cumulative Acreage Covered by Road Surfaces on NFS Lands after the first 15 Years and after Full Implementation of the Forest Plan (100+ Years) by Alternative[1] (currently there are 14,823 acres covered)

Alternative	Estimated Maximum Cumulative Acres Covered by Road Surfaces after First 15 Years of Implementation	Estimated Maximum Cumulative Acres Covered by Road Surfaces after Full Implementation (100+ years)
1	15,239	17,148
2	16,155	21,063
3	16,822	23,223
4	18,050	29,495
5	17,848	26,448
6	17,713	26,058
7	18,903	32,300

[1] Acres covered by road surfaces are calculated based on an average of 3 acres per 1 mile of road.

Soil mass movements (e.g., slumps, earthflows, debris avalanches, and debris flows) constitute the most potentially damaging type of erosion. They are thought to be the major cause of accelerated erosion resulting from resource management activities. Landslides may adversely affect soil quality. They have the potential to affect aquatic habitats both positively and negatively. Landslides have a positive effect by providing new sources of woody debris and gravel. They negatively affect aquatic habitats by destroying viable eggs by smothering and bed load overturn, and by destroying habitat elements for fish (pools, riffles, log discharge, etc.). Resource management activities would be eliminated if lands were switched from development LUDs to Recommended Wilderness or LUD II, reducing the risk of soil mass movements. Under all alternatives, Forest-wide standards and guidelines limit timber harvest on slopes over 72 percent gradient, as well as on soils classified with an extreme mass movement index.

As part of the effects analysis, the average landslide frequency from the Swanston and Marion (1991) study was applied to the estimated harvest levels likely under each alternative over the first 15 years of Forest Plan implementation. The proposed Forest Plan includes standards and guidelines and mitigation measures that were not in effect during the period of the landslide study (e.g., Riparian Standards and Guidelines, the removal of extreme hazard soils from the suitable land base, and BMPs). The Swanston and Marion (1991) landslide study was based primarily on large-scale clearcut logging with almost no buffers. Fewer landslides would be expected, on average, under the current or proposed Forest Plan.

For the purposes of this comparison, the life of the Forest Plan (up to about 15 years) is used because the landslide occurrences reported by Swanston and Marion (1991) reflect long-term averages. Landslides typically are associated with storm events and large amounts of precipitation, which are highly variable from one year to another. For example, widespread landsliding in headwater tributaries following basin wide clear-cut logging on Prince of Wales Island was triggered by intense rainstorms in 1961 and 1993 (Gomi et al. 2004). The numbers in Table 3.3-4 are used to compare the long-term landslide estimates that may result from the individual harvest levels proposed under each alternative. Despite the limitations listed in the footnotes (i.e., landslide frequencies are anticipated to be lower for each alternative than those displayed in the table), Table 3.3-4 provides a means to compare the relative level of effects under each alternative.

Table 3.3-4
Estimated Maximum Increase in Landslide Frequency over the First 15 Years of Forest Plan Implementation[1]

Alternative	Projected Maximum Acres Old Growth Harvested in First 15 Years[2]	Estimated Maximum Increase in Number of Landslides over First 15 Years
1	26,600	7
2	81,610	20
3	108,764	27
4	186,410	46
5	152,329	38
6	148,210	37
7	242,168	60

[1] This table uses the landslide frequency of one landslide per 2,052 acres in harvested and roaded areas cited in Swanston and Marion (1991) and subtracts off an estimated 0.289 landslide per 2,052 acres for unharvested acreas (based on their estimate of landslides being 3.5 times more prevalent in harvested vs. unharvested areas), in order to estimate the increase due to harvest and roading. It should be noted that Swanston and Marion (1991) measured landslide frequency based on large-scale clearcutting of large portions of watersheds that occurred between 1963 and 1983. Almost no harvest buffers were implemented during that time. The standards and guidelines protective of soil resources that are included in the current and proposed Forest Plans were not implemented. As a result, the estimates represent a maximum that likely far exceeds the landslide frequency that would likely occur under current and proposed timber management.

[2] Based on the acres of old growth scheduled for harvest by the Spectrum model over the first 15 years. These numbers assume that the maximum allowable acres would be harvested during this period, an unlikely scenario. Most likely, fewer acres would be harvested, particularly in the first decade. Any harvest would comply with the Forest Plan standards and guidelines, including buffers, unstable slope restrictions, smaller opening sizes, and BMPs.

Alternatives 1, 2, and 3 would have lower landslide potentials, and Alternative 6 would have a slightly lower landslide potential than under the current Forest Plan (Alternative 5). Alternatives 4 and 7 would result in increased potential, with the trend of increasing risk by alternative shown in Table 3.3-4.

Soil conditions could improve with the proposed changes to off-highway vehicle (OHV) management under each action alternative. Reflecting new national policy, the revised Forest Plan would close the Tongass National Forest to OHV use except where designated as open based on resource concerns and other criteria; however, the designation of open roads will need to be consistent with ANILCA. This approach would likely reduce the localized damage caused by OHV routes. In limited parts of the Tongass National Forest, soil degradation from steadily increasing OHV use over the last 15 years has been documented (USDA Forest Service 2006). Recently developed OHVs have enough power and traction to displace several inches of wet soil in a single pass (USDA Forest Service, 2006, unpublished). Avoiding routes that cross saturated soils with low-bearing strength would prevent ruts, soil compaction, and other resource damages (USDA Forest Service 2006, unpublished). OHV routes on the Yakutat Forelands have changed wetlands, created chronic soil disturbance, and caused sedimentation (USDA Forest Service, 2006, unpublished). By limiting OHV users to defined areas, the revised Forest Plan would address these issues before degradation occurred, the preferable option both ecologically and financially (USDA Forest Service 2006).

Cumulative Effects

Cumulative effects to soils would include both the effects discussed above and other potential effects related to activities outside of NFS lands. The total area within the Tongass National Forest boundary, including both NFS and non-NFS lands, is about

17.8 million acres. Of this area, non-NFS lands make up approximately 6 percent (1.06 million acres). A high percentage of the productive old growth on the non-NFS lands has been or can be expected to be harvested over the next 100+ years (see *Biodiversity* section *Cumulative Effects* subsection). Other reasonably foreseeable future activities on these lands include mining, recreation and tourism, growth of human settlements, transportation projects, and energy and transmission projects. Management activities on non-NFS lands are not held to the Region 10 soil standards; however, BMPs are required under the Alaska Forest Resources and Practices Act, including detailed regulations related to providing notification prior to timber harvests and managing riparian areas. The state forester must protect riparian areas from the significant adverse effects of timber harvest activities on fish habitat and water quality. These measures are designed to avoid soil erosion and sedimentation near streams. Martin (1996) compared pre- and post-harvest basins on non-NFS lands and found short-term effectiveness of these BMPs. Martin (1997) evaluated BMP effectiveness, including those designed to reduce soil erosion to mitigate turbidity. He found BMPs minimized sediment delivery and effectively maintained turbidity at comparable non-harvest levels. Arians (2003) includes several studies that compared pre- and post-harvest basins and indicated that logging with the BMPs does not result in significant effects to soils that would result in stream sedimentation and damage to fish. Despite these BMPs, some landslides, soil erosion related to duff removal, and losses in site productivity likely have occurred and will continue to occur on non-NFS lands. However, cumulatively, non-NFS lands represent only 6 percent of all of the soil resources in Southeast Alaska within the Tongass boundary. Potential impacts to the remaining 94 percent of soil resources would be mitigated through implementation of standards and guidelines and BMPs associated with each of the alternatives. The 2005 monitoring (USDA Forest Service 2005b) found that overall soil and water BMPs were implemented and found to be effective in Tongass timber harvest and road construction activities. Based on monitoring results, no changes were recommended to Forest Plan standards and guidelines for attaining State of Alaska water quality standards. Furthermore, effects of harvest on soil resources would ultimately be considered at the project-specific levels, ensuring minimal adverse cumulative effects to soil resources.

Similarly, roads are more prevalent on non-NFS lands than on NFS lands. Projected future road miles and densities under each alternative on both NFS and non-NFS lands are shown in Tables 3.6-8 and 3.6-9 of the *Fish* section of this chapter. In addition to approximately 4,942 total road miles currently on NFS lands, an additional 3,762 miles currently exist on non-NFS lands within the Forest boundary, and most of these roads are associated with timber harvest activities. Road densities are relatively high (2.27 miles per square mile) on non-NFS lands, resulting in commitment of soil resources; however, cumulative future road densities inside the Forest boundary are considerably lower, ranging from 0.39 mile per square mile under Alternative 1 to 0.57 mile per square mile under Alternative 7 (see the *Fish* section for additional information). As described earlier under the discussion of the potential direct and indirect effects to soils from roads, at the Forest Plan level, the overall difference in roaded area is a good indication of how site-specific effects are likely to vary among alternatives. This approach also applies to cumulative effects. Standards and guidelines, BMPs, and other relevant mitigation measures are applied at the project level to minimize potential adverse effects. Under all but Alternatives 4 and 7, the cumulative acres of road surfaces would be equal to or less than under the current Forest Plan. Reductions in soil productivity losses and soil erosion would correlate with lower cumulative road densities.

Overall, the cumulative effects of considered alternative actions combined with other non-NFS lands actions would increase the potential for cumulative effects to soil resources. Potential cumulative effects of harvest, road building, and other actions would be evaluated on a project-specific basis ensuring that any adverse effects to soil resources would be reduced, moderated, mitigated, or eliminated.

Mitigation

Forest-wide standards and guidelines for the soils resource are the same in all alternatives (see the Chapter 4 of the current Forest Plan and the proposed Forest Plan), and will apply to all site-specific projects. Forest-wide standards and guidelines are followed to mitigate the effects of management activities. They are designed to minimize accelerated soil erosion and maintain long-term soil productivity. They include soil conservation practices and incorporate the applicable BMPs (see Soil and Water Handbook). Annual monitoring (described in Forest Service Manual 2554) of BMP implementation and effectiveness helps ensure that water quality goals, and standards and guidelines, are met during project implementation (see Forest Plan, Chapter 6).

Water

Affected Environment

The Tongass National Forest can be characterized by its abundance of water. The maritime climate brings precipitation nearly year-round, with the heaviest amounts occurring from September through January. Coastal low-elevation rain forests thrive in this maritime climate. Thousands of miles of shoreline and hundreds of bays and inlets characterize the marine environment of the Tongass. An important consideration for all water-related issues is the effect that changes in water flow and quality have on important aquatic resources, especially fish.

The water environment of the Forest can be described in terms of climate, streamflow regimen, water quality, floodplains, wetlands, riparian areas, watershed condition, and water use. There are literally thousands of watersheds within the 26,000 square miles that make up the Tongass National Forest. Climate is described in the *Climate and Air* section; other factors are summarized in the following subsections.

Streams, Lakes, and Flow Regimen

Streams and rivers on the Tongass produce a large volume of water per unit of land. Much of the flow originates or passes through thousands of small to large lakes. Both glacial and non-glacial river and stream systems occur on the Tongass, and runoff varies greatly between the two stream systems. Runoff from glacially fed streams usually starts in June in response to snow and ice melt, reaching peak flows in July and August. Runoff drops rapidly in October and low flows occur from December through April. Runoff from non-glacial streams tends to respond to high precipitation events; therefore, the highest flows tend to be in October and December and the lowest flows between January and March, and mid-May to August. Many factors influence how timber management activities may affect runoff, and most are site-specific. Roads and timber harvest can affect the amount and timing of the runoff. In studies conducted in the Pacific Northwest, factors, especially those relating to roads, affect runoff patterns; although, site-specific conditions including hillslope gradient, topography, soil type, and rainfall all influence the level of effect (Coe 2004).

Stream channels and lakes are categorized by class based on their fish production values. Although there are additional details (see the *Glossary* for full definitions), stream classes are generally defined as follows:

- Class I streams and lakes have anadromous or adfluvial fish or fish habitat: or, high-quality resident fish waters, or habitat above fish migration barriers known to provide reasonable enhancement opportunities for anadromous fish.

- Class II streams and lakes have resident fish or fish habitat and generally steep gradients (6 to 25 percent or higher) where no anadromous fish occur, and otherwise not meeting Class I criteria.
- Class III streams are perennial and intermittent streams that have no fish populations or fish habitat, but have sufficient flow or sediment and debris transport to directly influence downstream water quality or fish habitat capability.
- Class IV streams are intermittent, ephemeral, and small perennial channels with insufficient flow or sediment transport capability to directly influence downstream water quality or fish habitat capability. Class IV streams do not have characteristics of Class I, II, or III streams, and have a bankfull width of at least 0.3 meter (1 foot).

In addition, the Tongass uses a stream channel classification system based on the Alaska Region Channel Type Classification System (Paustian et al. 1992). Streams are categorized into channel types, which are grouped into nine process groups, or combinations of similar channel types based on major differences in landform, gradient, and channel shapes (see Appendix D in the Forest Plan for a full description). These are used to assess watershed conditions, fish habitat production capabilities, and sensitivity to management activities (see the *Fish* section of this chapter for additional information). Approximately 65 percent of the stream channels on the Tongass are classified in the high gradient contained process group (Table 3.4-1).

Approximately 44,000 miles of stream have been mapped on the Forest (Table 3.4-1). There are also streams on the Forest that have not been mapped because they require ground surveys to locate. Many of these are small low-flow, high-gradient Class III and IV headwater streams, but others contain valuable aquatic habitat. Additionally, some 250,000 acres of lakes are present on the Forest lands.

Water Quality

The State of Alaska sets water quality standards for chemical, physical, and biological parameters for waters on National Forest System (NFS) lands. The Alaska Department of Environmental Conservation (ADEC) and the Forest Service have agreed that the USDA Forest Service is the agency responsible for monitoring and protecting water quality on the NFS lands of Alaska for the purpose of meeting the Clean Water Act, as amended. Best Management Practices (BMPs), as described in the Soil and Water Conservation Handbook (Forest Service Handbook 2509.22, Region 10 Amendment, July 2006), the Alaska Nonpoint Source Pollution Control Strategy, and the Alaska Water Quality Standards (18 AAC 70) together form the “Forest Service Alaska Region Water Quality Management Plan,” as agreed to in the Memorandum of Agreement dated April 6, 1992 (ADEC and USDA Forest Service 1992). With implementation of this Plan, the State of Alaska recognizes that the Forest Service BMPs are the primary means to protect water quality from nonpoint sources of pollution. In 1997, ADEC determined that the Forest Service BMPs meet or exceed the BMPs contained in the Alaska Forest Resources and Practices Act and Regulations (11 AAC 95) (Brown 1997).

Stream Temperature

Maintaining proper water temperature is critical for the health of aquatic ecosystems. Anadromous fish and other aquatic species are sensitive to water temperature with very low or high temperatures causing adverse conditions. Often in streams with salmon and trout, high water temperature is of greatest concern. Timber harvest and road construction have the potential to reduce stream shade and raise water temperatures. Forest Plan standards and guidelines minimize riparian harvest (see the subsection on Riparian Areas below) in order to maintain stream-side shade.

Table 3.4-1
Mapped Stream Miles by Process Group and Stream Class[1] for each Ranger District Group[2]

Stream Process Group	Class	Northern Ranger Districts	Central Ranger Districts	Southern Ranger Districts	Total
Alluvial Fan	I	236	47	134	**416**

[1] Miles are only those currently mapped and in the GIS database excluding lake channels. Additional unmappable streams are present, but have not been located through on-the-ground surveys, especially Class 3 and 4 streams that are greatly underrepresented in the database. Numbers may not add up precisely because of rounding. See Paustian et al. 1992 for a description of the stream process groups and the glossary for a definition of stream classes.
[2] Northern Districts=Admiralty, Hoonah, Juneau, Sitka, and Yakutat; Central Districts=Petersburg and Wrangell; Southern Districts=Ketchikan-Misty Fiords, Thorne Bay, and Craig
[3] Includes areas such as ice fields, connector streams not field surveyed, braided glacial river channels, culverts, and karst
Source: GIS database, July 2006

An analysis of legacy stream temperature data collected on Prince of Wales Island was completed in 2004. From 1997 to 2002, state water quality criteria for stream temperature were exceeded during warm weather in both harvested and unharvested watersheds (Walters and Prefontaine 2005). In 2004, state water quality criteria were exceeded in all three case study watersheds, two of which are unharvested (USDA Forest Service 2004c). Konopacky Environmental (1996) also did not detect stream temperature increased that could be characterized as differing significantly between logged and unlogged watersheds. High stream temperatures in Southeast Alaska are likely to occur under natural conditions during warm, rainless weather and result in low stream flow periods regardless of watershed harvest levels or extent of past riparian harvest.

Sediment and Other Factors

Sediment is solid materials that were derived from the natural weathering of rock or from erosion of areas modified by man, such as roads, agricultural lands, or urban areas. Sediments are carried and deposited by wind, water, and ice, and may be transported as either suspended load or bedload in streams. Suspended sediment is carried within the water column, while bedload material moves via rolling or bouncing along the bottom of the stream or riverbed. Suspended sediment causes water to have a turbid or murky appearance. Under natural conditions, the great majority of suspended load and bedload transport occurs during storm runoff events.

Soil mass movements (landslides), streams cutting new channels, and bank erosion are the main natural processes creating sediment. Landslides cause large, but temporary, increases in suspended and bedload sediments. Stream and riverbed or bank erosion may contribute to sediment over long periods of time. Steep terrain and large amounts of rainfall make the soil sensitive to erosion if the organic material covering the soil is disturbed. High rainfall also makes soils sensitive to sediment production by road construction and timber harvest activities.

In Southeast Alaska, suspended sediment loads in non-glacial streams in undisturbed watersheds are very low. Concentrations of suspended sediments range from less than 10 parts per million (ppm) in the winter to occasionally over 100 ppm in the fall during storm runoff periods (Schmeige et al. 1974). Suspended sediment in glacial streams is highly dependent on the volume of water flow from snow and ice melt. At high flows, concentrations may reach from 200 to more than 600 ppm; at low flows during winter, suspended sediment concentrations seldom exceed 20 ppm (Schmeige et al. 1974).

ADEC has established numeric criteria for turbidity standards (ADEC 2006a). Turbidity in Alaska correlates with suspended sediment, although the exact relationship varies by region and stream type (Lloyd 1987, Lloyd et al. 1987) and has not been determined in Southeast Alaska. Turbidity data collected during culvert installation or road construction suggests few instances where the state criteria have been exceeded (USDA Forest Service 2004c).

Changes in any of the physical or chemical properties of water can directly affect water use by people, fish, and wildlife. Sediment input to streams and turbidity are the two water quality factors most likely to be affected by alternatives. Other factors, such as temperature and dissolved oxygen, are not expected to change appreciably by alternative and, therefore, they are not discussed further in this section.

Current road construction methods and culvert installation activities have little effects on stream turbidity. The most recent monitoring of turbidity relative to various forestry activities have found few exceedances of the state turbidity standards (USDA Forest Service 2004, Monitoring reports). Of 12 replacement culvert installations monitored in 2004, 10 always met the turbidity standard for drinking water and 11 of the sites met the standard for fish propagation within 48 hours of the construction activity. Typically water returned to less than 5 nephelometric turbidity unit (NTUs) over background shortly after construction.

Recent monitoring was conducted to determine effects of road construction (including a bridge) on meeting turbidity criteria. The study was done on Upper Shaheen Creek in 2004 using the more stringent drinking water criteria. The results are preliminary, but suggest some short-term exceedance of the 5 NTU criteria. Of 50 days of continuous monitoring (when upstream and downstream sites were both monitored) , 11 days had some exceedance; of these, 9 were short term (less than 15 minute spikes in turbidity), while the remaining 2 exceedances were up to 30 minutes. Similar results were found in 2003, when 32 and 51 of 54 monitored culvert installations met drinking water, and fish production turbidity criteria, respectively (Monitoring Report summary for 2003)

Floodplains

Executive Order 11988 directs federal agencies to provide leadership and take action on federal lands to avoid, to the extent practicable, the long- and short-term adverse impacts associated with the occupancy and modification of floodplains. The Forest's floodplains are typically found in broad, flat, alluvial U-shaped valleys, are forested, and usually support plant communities having an overstory of Sitka spruce or Sitka spruce and western hemlock. The shrub understory is variable and may include blueberry, skunk cabbage, devil's club, salmonberry, and alder. Supporting this vegetation are well-, moderately well-, or somewhat poorly-drained, deep mineral soils with thin organic surface layers. Based on channel type characteristics, floodplains are associated with 9 percent of the 42,700 linear miles of the streams mapped on the Forest and are typically protected through identification and designation of riparian management areas and associated Riparian Standards and Guidelines.

Riparian Areas

Riparian areas include the stream channel and any stream-associated vegetation (plants dependent on a continuous source of water), and may include additional stream channel features such as floodplains and alluvial fans. Riparian ecosystems previously harvested for timber are now in various stages of secondary plant succession. With the exception of where the ground is highly disturbed, the species composition on these secondary successional riparian areas is very similar to the riparian vegetation prior to timber harvest, with Sitka spruce, red alder, and western hemlock dominating the tree canopy (USDA Forest Service 1997a). On the more disturbed sites, the vegetation is often similar to primary successional species, such as what occurs following deglaciation, with red alder the most common component.

Current management emphasis under the current Forest Plan is to maintain riparian areas in mostly natural conditions for fish and other riparian-associated resources. Management direction requires no-harvest buffers for Class I, II, and III streams with the widths depending on stream channel process groups. In addition, reasonable assurance of windfirmness must be provided for buffers, which may or may not include additional buffer width depending on site conditions. An evaluation of how well reasonable assurances of wind-firm buffers are working in high-gradient streams on the Tongass was recently conducted (Paustian et al. 2006). Additionally, recent literature was reviewed as part of this study to help assess the need for buffers on these streams (Landwehr 2006). Although field survey information is preliminary, blowdown has averaged about 5 percent in these buffers, which include standard buffers to slope break. The reasonable assurance of wind-firm buffer portion could not be determined at most of the sites. Based on the relative stability of these buffers, and considering recent literature that helps indicate the likely benefit to water and ecology of the systems from these buffers, the recommendation by these authors was to retain these wind-firm buffers as part of the standards and guidelines.

Prior to implementation of the current Forest Plan, approximately 66,000 acres of riparian productive old-growth forest were harvested, including approximately 295 acres that are now within Wilderness (USDA Forest Service 1997a). This represents about 13 percent of the original 490,000 acres of riparian productive old growth (POG) outside wilderness (USDA Forest Service 1997a). Most of this harvest, approximately 63,800 acres, took place between 1950 and 1997. This is approximately 1,329 acres per year. However, following implementation of the current Forest Plan, beginning in 1997, recent harvest in riparian areas has been much lower because it has been limited to road crossings (because no other harvest is allowed in riparian areas).

Watershed Condition

For land within the Tongass National Forest boundary, including all ownerships, 77 percent of the watersheds were classified as healthy in 1992 (i.e., having watershed functions and conditions generally in balance) (USDA Forest Service 1995a). For Tongass NFS land in 1992 (excluding other ownerships), 87 percent of the watersheds were classified as having satisfactory watershed conditions, 10 percent were classified as having declining watershed conditions, and 3 percent were classified as having unsatisfactory watershed conditions (USDA Forest Service 1995b). Watershed evaluation, has continued in recent periods. Assessments have included a GIS database evaluation that identified 25 watersheds of concern (USDA Forest Service 2001a). Follow-up on these evaluations are underway (Paustian 2005). The 1997 Forest Plan included increased protection for headwater streams and their watersheds. Standards and guidelines considered to be important for protection of watersheds by the Alaska Anadromous Fisheries Habitat Assessment (USDA Forest Service 1995a) have been implemented Forest-wide. Also, harvest and road construction have greatly decreased since the early 1990s (refer to the *Timber* section), and 94 miles of roads have been decommissioned between 1997 and 2005 (refer to the *Transportation and Utilities* section); therefore, watershed conditions (e.g., sediment input, stream temperature, fish passage) in many watersheds on the Tongass are likely to have remained stable or improved, although some ongoing impacts remain (e.g., large woody debris input, road and hillslope failures).

There has been about 28,000 acres of harvest in Riparian Management Areas across the Tongass (USDA Forest Service 2006a, Tongass Young-Growth Management Strategy, Exhibit 7). Approximately 15,000 acres of the total contain riparian young-growth stands that will potentially benefit from thinning treatments designed to promote future large wood recruitment. Sustained input of large wood is necessary to maintain stream channel functions and productive fish habitat conditions in Southeast Alaska watersheds. Storing and decommissioning of additional roads would improve habitat quality, fish passage, and water quality as they are treated.

ADEC is responsible for providing a list to the U.S. Environmental Protection Agency (EPA) of the status of water quality within the state. The state makes a determination of which state waters (e.g., streams, rivers, bays) exceed state water quality standards and are limited by point and/or non-point sources of pollution, which may require additional controls to meet state water quality standards. Waters that fit this definition are put on a list as designated under Section 303(d) of the Clean Water Act, which is published by the state and sent to EPA. State waters in this category are known as waters on the 303(d) list. The most recent list for 2004 (ADEC 2006b) includes seven water bodies in Southeast Alaska that are directly or indirectly impaired due to forest management practices. This includes two water bodies (Katlian River and Nakwasina River) listed as impaired for non-attainment of the sediment and turbidity standards due to harvest activities, including road maintenance and riparian harvest. Four locations (Hobart Bay, Schultz Cove, Thorne Bay, and Twelve Mile Arm) have marine nearshore bottom areas impaired from past log transfer facility operations. One location, Ward Cove, is indirectly affected from log processing operations as part of the local pulp mill activity that is no longer occurring. All five exceed state residue standards; Ward Cove also exceeds dissolved gas standards. However, water quality conditions at sites formerly affected by forest practices have been improving because three sites that were included on the previous 303(d) 2 years earlier were removed in the latest report. These include Cube Cove, East Port Frederick, and Klawock Inlet, which are all log transfer facilities. Additionally, part of Ward Cove has been removed due to restoration actions related to pulp mill water quality impacts.

Water Use

Key water uses on the Forest include public water supply, recreation, growth and propagation of fish, and hydroelectric power generation. The Forest supplies domestic water for 23 permanent communities, and about 55 Class A and B public water systems are located in the vicinity of the Tongass National Forest Boundary. Ketchikan, Sitka, and Petersburg have congressionally designated municipal watersheds, and another six communities have non-congressionally designated municipal watersheds. In addition, water is supplied from the Forest to fish hatcheries, industrial sites, and resorts. Hydroelectric generation continues to be used in many places throughout the Forest to provide electricity for mining, sawmills, communities, and other uses. There are six major power installations on the Tongass National Forest: the Snettisham and Gold Creek south of Juneau; Beaver Falls, Ketchikan Lakes, and Swan Lake east of Ketchikan; Lake Tyee near the Bradfield River; and Blue and Green Lakes south and east of Sitka. Additional installations and interties between installations are proposed. The *Lands* and the *Transportation and Utilities* sections of this chapter address planned hydroelectric projects.

Environmental Consequences

Direct and Indirect Effects

This section considers the effects of forest management activities on stream flows, wetlands, public and private water supplies, water quality, and cumulative effects. The effects of timber harvest and roads on fish habitat and riparian resources are discussed in the *Fish* section of this chapter. The effects of sedimentation caused by soil erosion and landslides are discussed in the *Soils* section of this chapter. The effects on potential hydroelectric projects are discussed in the *Lands* section, and the effects of log transfer facilities on the marine environment are discussed in the *Transportation and Utilities* section of this chapter.

Forest management activities affect water quality and quantity, as well as the timing of water flows through alteration of soil and watershed conditions. Most watersheds are in a state of dynamic equilibrium where changes occur naturally because of changes in weather patterns. Because of the overriding influence of climate and basin resiliency, changes in streamflow and sediment delivery resulting from management activities (e.g., timber harvest) are difficult to measure.

Water Quantity

Little is known about the effects of timber harvest and roads on stream flows in Southeast Alaska watersheds. However, many studies in the Pacific Northwest indicate roads and harvest may affect runoff timing and quantity of peak flow depending on many factors, including precipitation, soil depth, lithology, road design, hillslope gradient, and topography (Coe 2004). The potential effects of changes in stream flows within watersheds Forest-wide are expected to vary depending on the noted factors, as well as the relative amount of harvest and roads and the applicable Forest-wide standards and guidelines. The effects from changes in stream flows in a particular watershed can only be estimated during project planning, at which point the rate of entry into watersheds and locations of proposed roads and harvest units would be analyzed. The actual effects on stream flows can only be determined by site-specific monitoring.

Water Use

The Municipal Watershed Land Use Designation (LUD) is applied to 45,236 acres in 11 watersheds serving 9 incorporated cities and boroughs (Ketchikan, Petersburg, Sitka, Juneau, Wrangell, Kake, Klowock, Craig, and Hydaburg [see the amended Forest Plan, Chapter 3, Municipal Watershed under all Alternatives]). All of the alternatives would include the same protections to these watersheds. Watersheds serving unincorporated communities and other non-municipal water systems would be managed under Forest-wide standards and guidelines (see the amended Forest Plan, Chapter 4, Soil and Water). These stream locations are designated by ADEC as drinking water streams Class A or B, which include municipal and non-municipal water intakes. Other than the municipal sites, other streams could be affected by Forest Service actions that include harvest and road building in the watersheds where these streams are located. While most of the current sites have LUD designations that do not allow timber harvest under any alternative, many of the watersheds where these sites occur (Class A and B drinking water designations) have LUD designations of timber harvest. Among sites with timber harvest LUD designation in watersheds with these Class A or B designations, Alternative 1 has the least and Alternative 7 has the most. Prior to actions in any of these watersheds, the Forest Plan (Chapter 4, Soils and Water Standards) requires the Forest Service to conduct a watershed analysis and consult with ADEC as well as with owners and operators of public water systems prior to authorizing management activities that may cause pollution.

Water Quality

Riparian areas, as a component of aquatic and riparian ecosystems, would continue to be protected through use of the Riparian Standards and Guidelines under all alternatives, which protects water quality parameters such as stream turbidity, temperature, and nutrients. Protection for riparian areas would be the same under all alternatives at site levels. In addition, the application of BMPs would minimize or prevent adverse effects on water quality from the limited amount of riparian area within yarding corridors and stream road crossings, and from any non-commercial timber harvest that may occur. See the *Soils* section for further discussion on potential affects to water quality.

Cumulative Effects

One of the main cumulative factors affecting water quantity, use, and quality, in addition to actions taken on NFS lands, is ongoing and additional regional land development actions on non-NFS lands. These actions, in addition to the various effects of the considered alternatives, may have compounding effects on water conditions. While BMPs applied on NFS lands would moderate these effects, some effects on water may remain, and with the addition of other actions, may increase risk to water resources. One of the factors associated with potentially adverse effects to water are roads and associated actions such as timber harvest, culvert and bridge installation, and potential hazardous substance spills. While the effects would vary with location and type of activity, the amount of road miles is a partial indicator of cumulative effects region-wide. Table 3.4-2 shows the change in road miles on a regional basis, including non-NFS roads. Currently, there are about 4,941 total road miles (including all authorized and non-system roads) on NFS lands and an additional 3,756 miles on non-NFS lands within the Forest boundary. Many of these roads are associated with non-NFS timber harvest activities. In general, timber harvest activities on non-NFS areas are not as protective of stream riparian areas. Reduced protection of these areas has a greater risk of increasing impacts to water quality. Therefore, roads constructed on non-NFS lands may be associated with greater water quality and quantity impacts per mile of road than on NFS lands. Generally, however, the amount of roads may be an indicator of cumulative effects on water resources of the Tongass National Forest and adjacent areas; therefore, the cumulative effects to water resources would generally be proportional to overall changes in road miles. NFS road development under Alternative 1 would have the lowest contribution to cumulative effects by increasing total NFS road miles by about 16 percent over existing conditions; however, road construction on both NFS and non-NFS lands together would result in a total increase in road miles of 34 percent because non-NFS road development would likely increase substantially. Alternatives 4 and 7 would have the largest cumulative effect when including all roads, resulting in an increase in road miles equal to about 82 and 92 percent over existing conditions, respectively. The other alternatives (2, 3, 5, and 6) would result in a cumulative increase in road miles between 49 and 70 percent over existing conditions, when both NFS and non-NFS roads are included.

Table 3.4-2
Estimated Number of Road Miles on All Lands within the Tongass Forest Boundary for Each Alternative after Full Implementation of the Forest Plan (approximately 100+ years)[1]

		Alternative						
Road Categories	**Existing**	**1**	**2**	**3**	**4**	**5**	**6**	**7**
Total New Miles on NFS Lands		774	2,079	2,799	4,890	3,874	3,744	5,825
Total Miles on NFS Lands	4,941	5,715	7,020	7,740	9,831	8,815	8,685	10,766
Total Miles on Non-NFS Lands[2]	3,756	5,970	5,970	5,970	5,970	5,970	5,970	5,970
Total Miles on All Lands	**8,697**	**11,685**	**12,990**	**13,710**	**15,801**	**14,785**	**14,655**	**16,736**

[1] Assumes full implementation of Forest Plan at ASQ levels plus future non-NFS harvest. Roads on NFS lands adjusted for fall down.
[2] Assumes an increase of 2,214 road miles on non-NFS lands over 100+ years. Annette Island is included because it is surrounded by areas within the Forest boundary.

While less directly tied to water quality and quantity conditions, the amount of timber harvest may also be an indicator of cumulative effects to water conditions because of potential effects on sediment input, water temperature, stream detritus input, and flow patterns. Tree harvest areas in the Tongass National Forest are primarily characterized as POG vegetation regions. POG in 1954 accounted for about 34 percent of the land area within the Tongass National Forest boundary, which includes NFS lands as well as state and private lands. Therefore, land disturbance related to harvest is primarily limited to a small portion of the total land area. Non-POG areas include areas with small trees, muskeg, or wetlands; all regions where streams may be common; and ice fields and rocky mountainous areas where few streams may be present.

Table 3.4-3 indicates the cumulative portion of POG area that would be harvested within the Forest boundary (including all non-NFS lands) under each alternative, and the portion of all lands inside the Forest boundary that would potentially be disturbed by timber harvest. (This latter analysis represents an index of overall watershed disturbance associated with vegetation removal by timber harvest and does not consider roads outside of harvest units, urban areas, etc., which are a minor portion of the total disturbance area.) Currently, most (87 percent) of the POG acreage within the Forest boundary has not been harvested. Considering all lands inside the Forest boundary, 95 percent of the total land base has not been subjected to vegetation removal by timber harvest (Table 3.4-3). Alternative 1, including non-NFS harvest, would result in a reduction in POG area to 82 percent of the original acreage; 94 percent of all lands inside the Forest boundary would remain undisturbed by direct timber harvest. Alternatives 2, 3, 5, and 6 would result in 76 to 80 percent of the POG remaining; 92 to 93 percent of all lands would remain undisturbed by direct timber harvest after over 100 years of projected harvest. Alternatives 4 and 7 would have the greatest effect; POG would be reduced to 70 to 72 percent of the original area; 90 to 91 percent of the total land base would remain undisturbed by direct harvest. It is likely some local effects on water quality and, possibly, quantity, from all alternatives. On a Forest-wide basis, however, the overall effects would be very minor for all alternatives. As noted above for roads, lesser riparian protections on state and private lands would have a greater likelihood of causing adverse effects to water quality and quantity in watersheds on non-NFS lands, which could be compounded if NFS lands are harvested in the same watersheds. Potential cumulative effects of harvest, road building, and other actions would be evaluated at the project-specific level in order to ensure that any adverse effects to water resources would be reduced, moderated, mitigated, or eliminated.

Table 3.4-3.
Percent of Original POG Remaining on All Lands within the Tongass Forest Boundary and Percent of All Lands inside the Boundary that are Not Directly Disturbed by Timber Harvest after Full Implementation of the Forest Plan (approximately 100+ years)[1]

Alternative	Percent of All Original POG Remaining [2]	Approximate Percent of All Lands Not Disturbed by Timber Harvest [3]
Existing	87%	95%
1	82%	94%
2	80%	93%
3	78%	92%
4	72%	91%
5	76%	92%
6	76%	92%
7	70%	90%

[1] Assumes full implementation of Forest Plan at ASQ levels plus future non-NFS harvest.
[2] Original POG equals about 34 percent of all land area (17,869,000 acres) of this region.
[3] Value represents the percent of all 17,869,000 acres inside the Tongass boundary (plus Annette Island) that would be disturbed by timber harvest and is used as an index of overall watershed disturbance associated with timber harvest. It does not include the acreage of other forms of ground disturbance (e.g., roads, towns) beyond the harvest of POG.

The potential for future climate change is a factor that could affect water quality and quantity conditions on the Tongass. Some of the models developed for the region predict both changes in precipitaion and air temperature. The details of recent climate models (see the *Cumulative Effects* subsection in the *Fish* section) project slight decreases in summer rainfall (about 10 percent) and increased temperature.

Southeast Alaska is characterized by high rainfall, so small reductions have limited potential to significantly reduce stream flows. Streams, both in harvested and unharvested watersheds, have occasionally been documented with brief periods of temperature standard exceedances. Theoretically, if air temperature changes were large enough, these exceedances could become more frequent. Currently there are no 303(d) streams listed for temperature exceedance. Whether temperature changes would be large enough to cause changes to this level are unknown. However, in the short term that the amended Forest Plan will be in place before being modified again (likely 10 to 15 years), large magnitude changes in both stream flow and stream temperature are hightly unlikely. In summary, there is general agreement that the climate is warming and that summer precipitation is likely to decline. However, there is considerable uncertainty surrounding specific predictions of when and the magnitude, and even more uncertainty regarding the effect of these changes on water quantity and quality.

Wetlands

Affected Environment

Definition and Regulatory Aspects

The U.S. Environmental Protection Agency (EPA) and the U.S. Army Corps of Engineers (Corps) jointly define wetlands as "those areas that are inundated or saturated by surface or groundwater with a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, bogs, and similar areas." Wetlands are considered to be ecologically important for the physical, biological, and chemical functions they provide. The functions include flood flow moderation, groundwater recharge and discharge, wildlife and fish habitat, and water quality protection.

The Corps' Wetlands Delineation Manual (Experimental Laboratory 1987) provides the standards for determining areas of wetlands and deepwater habitats. Land areas are defined as wetlands when soil, hydrology, and vegetation all meet the technical criteria for establishing wetlands.

For federal regulatory purposes, wetlands are considered a subclass of Special Aquatic Sites (40 Code of Federal Regulations [CFR] Section 230.3) and have been deemed Waters of the United States (33 CFR 328.3). All waters of the United States are subject to regulation through the Clean Water Act by the Corps and EPA. Sections 404 and 401 of the Clean Water Act were created specifically with the intent "to restore and maintain the chemical, physical, and biological integrity of our Nation's waters." Executive Order 11990, as amended (42 U.S.C. 4321 et. seq.), requires federal agencies "to avoid...adverse impacts associated with the destruction or modification of wetlands...wherever there is a practicable alternative" and to "include all practicable measures to minimize harm to wetlands." Further, the agencies are required to preserve and enhance the natural and beneficial values of wetlands in carrying out their responsibilities.

Wetland Classification

The classification system, as described below, is based on U.S. Fisn and Wildlife Service's (USFWS's) classification of wetlands and deepwater habitats of the United States, developed by Cowardin et al. (1979).

Palustrine wetlands include the vegetated wetlands traditionally referred to as marshes, swamps, bogs, fens, and prairies. They include all nontidal wetlands dominated by trees, shrubs, persistent emergent plants, mosses or lichens, and all such wetlands that occur in tidal areas where salinity due to ocean-derived salts is below 0.5 percent. Palustrine wetland classes on the Tongass include emergent wetlands (including peatlands), scrub-shrub wetlands, and forested wetlands. Classes are described in the following paragraphs.

Forested class. Over half (53 percent) of the National Wetland Inventory (NWI)-mapped wetland acres on the Tongass are forested wetlands. Vegetation ranges from scrubby mixed conifer forests (greater than 20 feet high) to moderately productive mixed conifer, western, or mountain hemlock stands. Shrubs and forbs dominate the understory.

Emergent class. Approximately 25 percent of the NWI-mapped wetland acres are emergent. The emergent class is characterized by erect, rooted herbaceous plants, and mosses and lichens. Peatlands (muskegs) are included in the emergent class of wetland area on the Forest. In Southeast Alaska, all relatively open bogs that have a groundcover high in sphagnum mosses and/or sedges are called “muskegs,” and are a type of peatland.

Scrub-Shrub class. Approximately 13 percent of the NWI-mapped wetland acres are scrub-shrub. This class is the most vegetatively varied wetland class in Southeast Alaska. Plant species may include true shrubs, young trees, and tree and/or shrubs that are small or stunted because of environmental conditions. Scrub-shrub wetlands are associated with three broad wetland plant communities: scrub-shrub alder/willow, scrub-shrub evergreen/emergent, and forested scrub-shrub evergreen/emergent.

Lacustrine wetlands include all permanently flooded lakes, reservoirs, and tidal lakes with ocean-derived salinities below 0.5 parts per thousand. Approximately 5 percent of the NWI-mapped wetland acres are lacustrine.

Estuarine wetland system. Estuarine wetlands are those areas that are predominantly intertidal, and are those parts of the rivers or streams or other bodies of water having an unimpaired connection with the open sea, where the sea water is diluted with freshwater derived from land drainage. Less than 2 percent of the NWI-mapped wetland acres are estuarine.

Riverine wetland system. The riverine wetland system includes all channel-contained streams and rivers. These areas are bounded by uplands, channel banks, or palustrine wetlands dominated by trees, shrubs, emergent mosses or lichens. In braided streams, the riverine wetland system is bounded by the banks forming the outer limits of the depression within which the braiding occurs. Less than 2 percent of the NWI-mapped wetland acres are riverine.

Wetland Mapping and Distribution

On the Tongass, wetlands may be found from sea level to alpine elevations, and may include estuaries and riparian areas. Wetland acreage shown in Table 3.5-1 is from the NWI, which is available through USFWS. The NWI database wetland identification map is based on geography, visible hydrology, and vegetation as seen in high altitude imagery (USFWS 2006).

Table 3.5-1
Mapped Acres of Wetlands on the Tongass National Forest by Wetland System and Class

Wetland Systems	Wetland Classes	Acres
Palustrine	Forested	2,123,440
	Emergent (including peatlands/muskegs)	1,009,777
	Scrub-shrub	535,325
	Palustrine - undistinguished	51,675
Lacustrine		181,746
Estuarine		64,792
Riverine		46,427
Marine		9,092
Total Wetlands		**4,022,272**

Environmental Consequences

Direct and Indirect Effects

The physical, biological, and chemical integrity of wetlands in the Tongass is affected mainly through timber harvest operations, which include the construction and maintenance of roads, landings, stream crossing structures, marine access points, and log transfer facilities (LTFs). The magnitude of timber harvest-related effects to wetlands depends, in part, on the intensity, location, and duration of the timber harvest activity or road construction.

Limited research studies have been conducted on the effects of timber harvest or road building on wetlands in Southeast Alaska. The research on the effects of harvest on wetland systems have been primarily focused on regeneration of trees (Julin and D'Amore 2003, Duncan 2002). Studies on road construction on wetland sites have been focused on the effects to hydrology, and only a few wetland sites were studied (Glaser 1999, Kahklen and Moll 1999, McGee 2000). Wetlands are complex natural systems and these few studies may not represent the breadth of the potential effects to wetland functioning that could occur across the Tongass National Forest. Additionally, processes in a complex natural system, such as regrowth of a forest after harvest, contain random components and are not predictable at every scale or for every location.

Silvicultural operations, such as harvesting trees, are generally exempted from Corps permitting requirements. The construction or maintenance of forest roads in support of silvicultural practices, and temporary roads for moving mining equipment, are also generally covered under this exemption for the discharge of dredged or fill material into waters of the United States. This exemption is contingent on the construction and maintenance being conducted in accordance with the Corps' Best Management Practices (BMPs) as stated in 33 CFR 323.4(a)(6). These practices have been incorporated into BMP 12.5 of the Alaska Region's BMP Handbook (Forest Service Handbook 2509.22).

In each of the seven alternatives, the Forest-wide standards and guidelines (including BMPs) would be applied to activities in and around wetlands. The standards and guidelines that apply to wetlands are the same for all alternatives. They provide direction to avoid development activities in wetlands to the extent feasible, minimize effects on wetlands, and locate and design roads to minimize effects on wetlands. Project-level analysis and planning would be used to avoid construction in wetlands, and would provide site-specific plans to minimize effects.

Tree harvesting on wetland sites would have direct effects on the sites themselves and indirect effects on adjacent or nearby wetlands. The effects would include potentially altering hydrology, changing nutrient pathways, delivering sediment (which can diminish water quality), changing plant species composition and growth, and reducing shading. Harvesting trees in wetlands is not expected to convert wetlands to uplands. However, harvest would result in a short-term reduction in hydrologic and biogeochemical wetland functions that begin to return as soon as there is tree revegetation. The habitat functions provided by forest areas may require more time and forest regrowth to return. Habitat values for many species using forested habitat are discussed in the *Wildlife* section of this chapter.

In Southeast Alaska, forested wetlands have been found to successfully regenerate and grow into dense, differentiated stands after clearcutting (Julin and D'Amore 2003, Duncan 2002). Some of the habitat functions are dependant on, or related to, characteristics of the old-growth ecosystem, which would not develop over the life of the Forest Plan (10 to 15 years).

According to a study on regeneration of forested wetlands, tree growth was slow in Histosols (wet, organic soils), but it proceeded regularly and exceeded the minimum USDA Forest Service volume-production standard for commercial timberland (Julin and D'Amore 2003). Revegetation of forested wetland sites is expected to occur in the same timeframe as other forested sites, usually within 3 to 5 years. Site quality on wetland soils, however, may be lower than on sites with better drainage, and may require additional time for trees to reach merchantable size on wetlands compared to drier sites.

Construction of roads within wetlands permanently removes the wetland area and its functions under the roadbed itself. Additionally, crossing wetlands with roads without adequate provision for cross-drainage could lead to sedimentation from road construction or changes in hydrologic patterns.

There are approximately 1,079 existing road miles on wetlands on the Tongass, including non-system roads and closed roads. This represents 22 percent of the 4,941 total road miles. Table 3.5-2 shows the road miles by wetland classification that exist on the Tongass. The majority of these roads were constructed as part of forestry activities. There have been limited research studies done on the effects of forestry roads constructed in the past on wetlands or uplands in the Tongass National Forest. The results of the wetland and upland studies on the Tongass suggest that the hydrologic effects of roads remain within a few meters of the road (Glaser 1999, Kahklen and Moll 1999, McGee 2000). The results are similar to studies done in other areas with similar climates (cool, moist, and year-round precipitation). Researchers have studied the effects of ditching on peatlands in northern climates. In northern England, they found that the measurable effects of ditches on peatland hydrology were limited to less than 3 meters from the ditches (Stewart and Lance 1991, Coulson et al. 1990).

Table 3.5-2
Existing Roads and Maximum Miles of New Roads in Wetlands by Alternative after 100+ Years[1]

Reconstruction of a road for timber harvest maintains the original investment and makes it suitable and safe for the intended use. Reconstruction involves rehabilitation of the original roadbed. It can include cleaning ditches, replacing drainage structures, reinstalling bridges, and grading and shaping. Generally, reconstruction of existing roadbeds for timber harvest would not add impermeable surface to wetlands. However, some reconstruction can include upgrading a road and widening the roadbed. In the Forest-Level Roads Analysis, a few roads, specifically on Prince of Wales Island, have been recommended for upgrading and widening the roadbed (USDA Forest Service 2003c). Widening an existing roadbed in wetlands would add to the impermeable surface and increase the total effects to wetlands. The recommendations in the Forest-Level Roads Analysis would be the same for all alternatives. The estimated road miles to be reconstructed would vary by alternative, however, ranging from 925 total miles under Alternative 1 to 2,371 miles under Alternative 7. Alternatives 2 through 6 would reconstruct an estimated 1,784 to 2,100 total road miles (see Table 3.12-2 in the *Transportation and Utilities* section).

Some activities in road reconstruction have potential to affect wetland hydrology, such as replacing drainage structures or cleaning road ditches. This may have a positive or negative effect on wetland hydrology, depending on the condition of the existing road in the wetland. Road maintenance can include reconditioning the original road template, grading the road surface, cleaning roadside ditches, and removing vegetation that may encroach upon the road or block vision. In general, this would have no effect, or it could improve wetland hydrology in areas where drainage has become blocked.

The difference between alternatives in effects to wetlands generally falls within two categories: 1) short-term or long-term effects due to timber harvest, and 2) loss of wetland acres and function due to road construction. Acres of harvest and miles of roads proposed in wetlands can be used to provide comparisons between alternatives. However, actual acres of harvest in wetlands are likely to be lower, particularly in scrub-shrub and emergent wetlands, when acres are dropped in units with poor volume. Miles of road would likely be less than shown in this analysis because road layout for individual projects would avoid wetlands to the extent feasible, as required in the Forest-wide standards and guidelines. Also, there are standards and guidelines to protect beach and estuarine, riverine, and lacustrine areas. The beach and estuary fringe, an area of 1,000 feet slope distance around all identified estuaries and from all saltwater shorelines, is classified as unsuitable for timber activities and roads are discouraged. Riparian area protection varies depending on the classification of the stream. The Forest-wide standards and guidelines include a restriction on programmed timber harvest in riparian management zones and within 100 feet of Class I fish-bearing streams as well as Class II streams that flow into Class I streams. These standards and guidelines would provide further protection for wetlands that occur in estuarine, riparian, and lacustrine areas.

Tables 3.5-2 and 3.5-3 show the proposed maximum miles of road and acres for harvest under the alternatives. Alternative 5, the No-Action Alternative, would conduct harvest activities on a maximum of 123,000 acres and construct a maximum of 1,240 new miles of roads in wetlands. Alternatives 1 and 2 would maintain the most acres of undisturbed forest with less risk of adverse effects to wetlands due to harvest. Alternatives 1 and 2 include harvesting on approximately 18 and 52 percent of the wetland acreage proposed in Alternative 5, respectively. Alternatives 1 and 2 also propose constructing approximately 18 and 50 percent of the road miles in wetland proposed by Alternative 5, respectively. Alternative 3 is in the middle of the alternatives in terms of harvest acres and road construction in wetlands. It would include harvest activity on 71 percent of the acres in wetlands shown in Alternative 5 and construct 68 percent of the road miles. Alternative 6 proposes slightly less harvesting and road construction (97 percent of Alternative 5 for both). Alternatives 4 and 7 propose the highest level of harvest and road construction in wetlands. They would include approximately 36 and 65 percent more acres of harvest in wetlands than in Alternative 5, respectively, and 35 and 65 percent more miles of roads in wetlands to achieve that harvest, respectively.

Therefore, over time, Alternatives 7 and 4 would have a higher risk of direct and indirect effects to wetlands due to harvest and road work than Alternative 5, the current Forest Plan. Alternatives 1 and 2 would have the least risk of effects to wetlands. The acres of harvest and miles of road construction for Alternative 3 would be intermediate and its potential to affect wetlands would be somewhat lower than Alternative 5, while Alternative 6 would have slightly lower effects.

Table 3.5-3
Maximum Harvest Area in Mapped Wetlands by Alternative before after 100+ Years of Full Implementation[1]

Alternative	Palustrine Wetlands: Forested	Palustrine Wetlands: Scrub-Shrub	Palustrine Wetlands: Emergent (including peatlands and muskegs)	Lacustrine Wetlands	Estuarine/ Marine[2] Wetlands	Riverine Wetlands	Total Wetlands

Cumulative Effects

When considering effects to wetlands, it is important to look at both the land outside the National Forest System (NFS) lands and the cumulative effects of past, present, and reasonably foreseeable future activities. Individual wetlands provide important physical, biological, and chemical functions, and are not isolated from other resources when viewed on a larger scale. Surface and subsurface water, along with many organisms, move through the landscape. As discussed in the direct and indirect effects section, changes to or loss of functions in an individual wetland can have effects that extend beyond individual wetlands as they contribute to the overall functioning within a watershed and landscape.

Each landscape area or watershed has different physical, chemical, and biological characteristics and vegetation patterns. The significance of an addition to cumulative effects from a change in an individual wetland would depend on the amount and type of disturbance in the analysis area, wetland locations and distribution in the watersheds, the distance to other wetlands and waterbodies, and connectivity of hydrology and habitat between them. Assessing cumulative effects to wetlands will be done for individual projects for the relevant analysis area as part of the National Environmental Policy Act process in all alternatives. However, past plus expected harvest and road construction for forestry and other uses on all land ownerships can be used to compare the risk of the alternatives adding to cumulative effects.

Non-NFS lands comprise approximately 6 percent of the lands within the Tongass National Forest boundary and 22 percent of Southeast Alaska. Silviculture on non-NFS lands are generally exempt from the Corps' permitting requirements contingent on the construction and maintenance of roads being conducted in accordance with the general Corps' BMPs as stated in 33 CFR 323.4(a)(6). Timber harvesting on state, municipal, and private land is also governed by the Alaska Forest Resources and Practices Act of 1979 (AS 41.17). Alaska Forest Resources and Practices Regulations (Alaska Department of Natural Resources [ADNR] 2004) includes regulations designed to prevent adverse impacts to fish habitat and water quality from timber operations. The regulations are less extensive than the standards and guidelines that direct activities on the Forest. The state regulations provide direction to avoid and minimize road building, sedimentation, establishment of landings, and damage to vegetative cover when yarding across marshes and non-forested muskegs. The regulations also provide buffers for forested wetlands if classified as anadromous water bodies or tributaries to anadromous water bodies. Harvest and associated activities are not specifically regulated on forested wetlands that are otherwise classified.

Timber harvest can alter wetland function and type but is not expected to convert wetlands to uplands. The hydrologic and biogeochemical functions begin to return as soon as there is tree revegetation, but the habitat functions provided by forested areas may take longer and more forest regrowth to return. Some of the habitat functions are dependent on, or related to, characteristics of the old-growth ecosystem, which will not develop during the life of the Forest Plan (10 to 15 years). Therefore, the effects of a project may add to cumulative effects to wetlands or their functions, particularly habitat functions in an area. Habitat and habitat changes are discussed in greater depth in the *Biodiversity* section.

To compare the potential for cumulative effects due to harvest on wetlands, harvest was analyzed on lands of all ownerships within the Tongass Forest Boundary (plus Annette Island, which is surrounded by the Forest). There are approximately 17.87 million acres of land inside the Forest boundary. Approximately 30 percent of that land is currently in productive old growth (POG). Approximately 13 percent of the original POG on all ownerships in this area has been harvested through 2006. Thus, approximately 87 percent of POG on all ownerships is remaining. The percent of POG remaining on NFS lands is higher than for non-NFS lands (92 and 66 percent, respectively) due to the concentrated timber harvest areas on non-NFS lands. Looking at all land ownerships within the Forest boundary, the POG remaining in 100 years under full implementation of the Forest Plan would be greatest for Alternative 1, followed by Alternatives 2, 3, 6, 5, 4, and 7 in that order (Table 3.5-4). Therefore, the risk of cumulative effects to wetlands due to harvest would follow that same order.

Alteration of water flow in wetlands through increases in impervious surfaces reduces the time that water resides in wetlands or streams in a watershed and can lead to more severe flooding or more dry spells in streams. The effect of a road on an individual wetland, when added to other alterations to the hydrology in an area, could result in water flow alterations. In the Tongass, the impervious surfaces are generally forestry roads. These can be used to examine cumulative effects.

Table 3.5-4
Cumulative Percent of Original POG Remaining on All Ownerships in 2006 and Estimated Minimum Percent Remaining after 100+ Years[1] for All Lands within the Tongass Forest Boundary[2]

Remaining POG on All Ownerships in 2006 as a Percent of all Original POG	Remaining POG after 100+ Years as a Percent of Original POG						
	Alternative						
	1	2	3	4	5	6	7
87%	82%	80%	78%	72%	76%	76%	70%

[1] Assumes full implementation of Forest Plan at ASQ levels plus future non-NFS harvest.
[2] Annette Island is included because it is surrounded by areas within the Forest boundary.
Source: Tongass National Forest GIS database.

Road density is greater on the non-NFS lands within the Forest boundary than on the Tongass NFS lands due to concentrated harvest and more populated areas. Road density averages 0.19 mile per square mile on the Tongass NFS and 2.19 miles per square mile for non-NFS lands. The average for land of all ownerships is 0.31 mile per square mile; however, those are averages over a very large area and there is considerable variability. Table 3.6-9 in the *Fish* section of this chapter (percent frequency of Value Comparison Units [VCUs]) by road density categories for the Tongass and land of all ownerships) shows the large variability in road density across the Tongass. VCUs are roughly equal to a watershed.

No documentation was found regarding a threshold at which impervious surfaces interact to an extent to have a qualitatively or quantitatively different effect for wetlands in Southeast Alaska. In Washington State, a literature search to determine the best available science with which to evaluate cumulative effects of activities in wetlands revealed that there is disagreement about a specific threshold. The opinions in one report about the threshold to use, range from 10 to 20 percent impervious surfaces within a watershed. There were also scientists whose opinion was that specific thresholds were not accurate and that deterioration began immediately (Sheldon et al. 2005). The most conservative idea is that there is no accurate threshold, and that deterioration begins immediately. While cumulative effects will be analyzed during project analysis, comparisons can be made about the risk of adding to cumulative effects on wetlands associated with each alternative.

Table 3.5-5 shows the average future road density for each alternative for all ownerships. It includes forestry and other roads proposed for construction on NFS land and reasonably foreseeable roads on non-NFS lands. Alternatives 7 and 4 would result in the highest average road density. Therefore, in those alternatives, there is a greater risk of management actions adding to cumulative effects to wetlands. The average road densities for Alternatives 3, 5, and 6 are intermediate and their risk of cumulative effects would fall in the mid-range when compared to the other alternatives. Alternatives 1 and 2 would have the lowest risk of cumulative effects due to an individual project.

Table 3.5-5
Existing and Estimated Future Maximum Road Density (miles per square mile) for NFS Lands and for All Ownerships within the Forest Boundary by Alternative after 100+ Years[1]

		Alternative						
	Existing	**1**	**2**	**3**	**4**	**5**	**6**	**7**
National Forest Land	**0.19**	0.22	0.27	0.30	0.38	0.34	0.33	0.41
All Ownerships	**0.31**	0.42	0.47	0.49	0.57	0.53	0.52	0.60

Source: Tongass National Forest GIS database

Other activities also need to be considered when determining cumulative effects for past, present, and foreseeable future effects to wetlands. They include mineral extraction, transmission line projects, hydroelectric projects, transportation developments, expansion of cities, and recreational site development. Existing mining is at Greens Creek on Admiralty Island, Berner’s Bay north of Juneau, and other locations. Given the level of world pricing, an increase in exploration is expected. There are also several regional transportation projects and regional energy and transmission projects planned for construction. Each of these activities can include clearing vegetation and disturbing wetlands with construction and maintenance. Therefore, the activities have the potential to affect wetlands and their functions and would be considered during individual project analysis. The effects of these projects would be the same for each alternative.

Changes in Southeast Alaska’s climate (discussed in the *Climate and Air* section) could affect the size, type, and functions of wetlands and, therefore, could add to cumulative effects. While the models do not fully agree on the climate change predictions for Southeast Alaska, they generally predict warmer weather, with more winter rainfall, less snowfall, and a decrease in summer rain in some areas. That would likely result in lower soil moisture due to increased evaporation during warmer, dryer summer months. Also, a precipitation shift from snow to rain could lead to more water running off the landscape rather than being stored as snow. Snowmelt is an important water source for wetlands in the spring and summer.

Thus, increased evaporation and less water storage could lead to drier meadows or bogs and, possibly, fewer wetlands.

Changes in temperature could favor some plants and stress others. Longer growing seasons with warmer temperatures would likely result in faster growth. Those conditions would also favor more decomposition that could lead to changes in the organic matter in soils and bogs. Changes in climate could shift wetlands from being carbon sinks to sources of aerial and aquatic carbon due to more rapid decomposition during warmer summers. All of these factors could lead to changes in wetland types, such as shifts in vegetation from herbaceous to shrub, from shrubs to trees, or from bogs to more productive forests. However, as discussed in the *Climate and Air* section, the models do not always agree and the predictions for total precipitation in portions of Southeast Alaska differ.

This page is intentionally left blank.

Fish

Affected Environment

Fish and the aquatic resources on the Tongass National Forest provide major subsistence, commercial, and sport fisheries, as well as support traditional and cultural values. Abundant rainfall, streams with glacial origins, and watersheds with high stream densities provide an unusual number and diversity of freshwater fish habitats. These abundant aquatic systems of the Tongass provide spawning and rearing habitats for the majority of fish produced in Southeast Alaska. Maintenance of this habitat, and associated high-quality water, is a focal point of public, state, and federal natural resource agencies, as well as user groups, Native organizations, and individuals.

Approximately 12,700 stream miles and 4,100 lakes and ponds are mapped as Class I water bodies (based on Tongass GIS data); these water bodies are considered to be anadromous or high-value resident fish habitat. Another 8,800 stream miles and 4,700 lakes and ponds are mapped as resident fish habitat. Most of the Forest's streams and rivers empty into bays or estuaries, which are important during some life stages of anadromous species, as well as for many saltwater fish species. Marine invertebrates, such as clams and crabs, are commonly found in the estuaries and nearshore marine environment of Southeast Alaska. Some marine animals, including, Dungeness (*Cancer magister*), butter clams (*Saxidomes giganteus*), and other benthic and epibenthic organisms may be affected by upland management activities, such as timber harvest, road construction, and related log transfer and storage facilities.

Subsistence, commercial, and sport fisheries are all important to the way of life for Southeast Alaskan residents. Sport fishing is a favorite activity of residents and visitors. Hatcheries, and the enhancement of wild fish, among other aquaculture projects, contribute to resource availability and abundance. The primary fish species harvested in these fisheries are shown in Table 3.6-1.

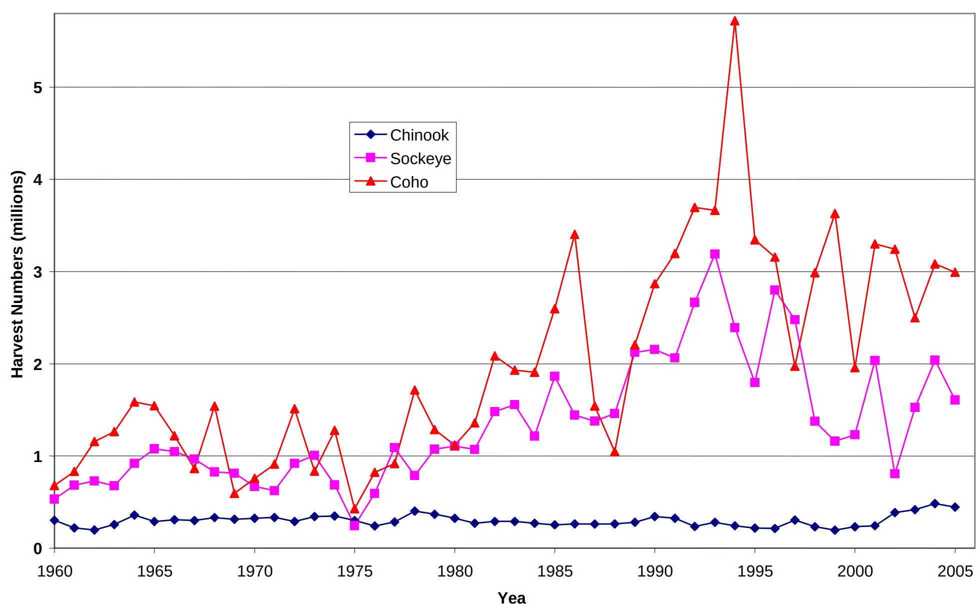
Table 3.6-1
Commonly Harvested Sport, Subsistence, and Commercial Fish

Species[1]	Sport	Subsistence	Commercial
Pink salmon (*Oncorhynchus gorbuscha*)	X	X	X
Chum salmon (*Oncorhynchus keta*)	X	X	X
Coho salmon (*Oncorhynchus kisutch*)	X	X	X
Sockeye salmon (*Oncorhynchus nerka*)	X	X	X
Chinook salmon (*Oncorhynchus tshawytscha*)	X	X	X
Cutthroat trout (*Oncorhynchus clarki*)	X	X	
Rainbow trout and steelhead (*Oncorhynchus mykiss*)	X	X	
Dolly Varden char (*Salvelinus malma*)	X	X	
Eulachon smelt (*Thaleichthys pacificus*)		X	

[1] Alternate names commonly used for the same species include pink or humpback; chum or dog; coho or silver; sockeye or red; Chinook or king; and eulachon, hooligan, or candlefish.

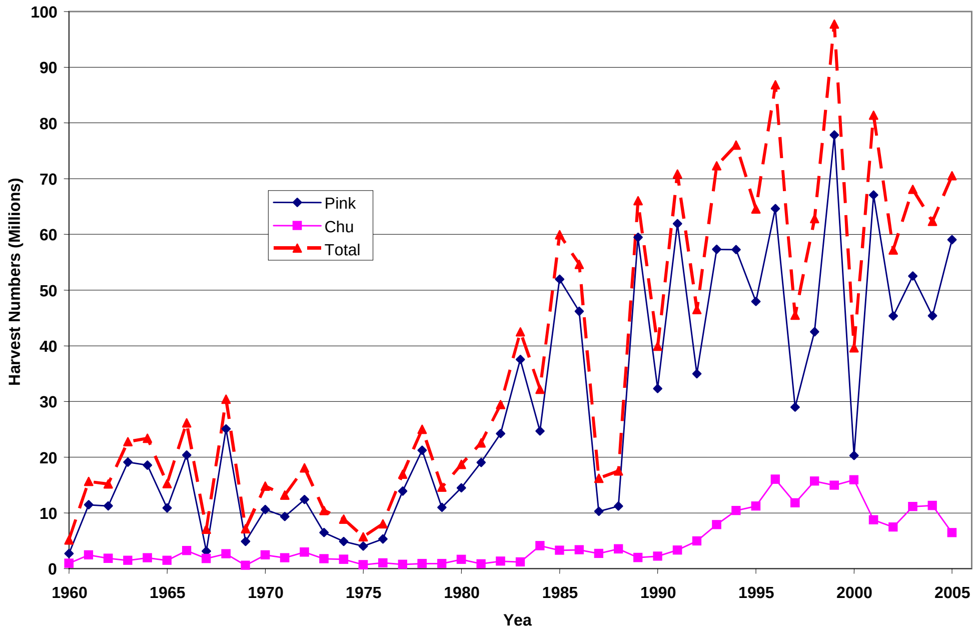
Commercial fish harvest in the waters of Southeast Alaska can fluctuate widely from year to year. For example, salmon harvest in Southeast Alaska averaged approximately 50 million fish between 1935 and 1940. It then declined steadily to less than 20 million fish in 1950. From 1950 to 1975, harvests were generally low, falling below 6 million fish in 1975 (Figures 3.6-1 and 3.6-2). Since 1975, harvest has been increasing in Southeast Alaska. Recent years where record harvest occurred for each of the main species were: Chinook (2004), sockeye (1993), coho (1994), pink (1999), and chum salmon (1996) (Bachman et al. 2005). Overall record harvest of total salmon occurred in 1999, when 98 million salmon were captured (Bachman et al. 2005). Overall, recent commercial salmon harvest (since early to mid-1990s) has remained high (Figures 3.6-1 and 3.6-2).

Figure 3.6-1
Commercial Harvest of Chinook, Sockeye and Coho Salmon in Southeast Alaska 1960 to 2005



Source: Bachman et al. 2005

Figure 3.6-2
Commercial Harvest of Pink, Chum and Total Salmon in Southeast Alaska 1960-2005



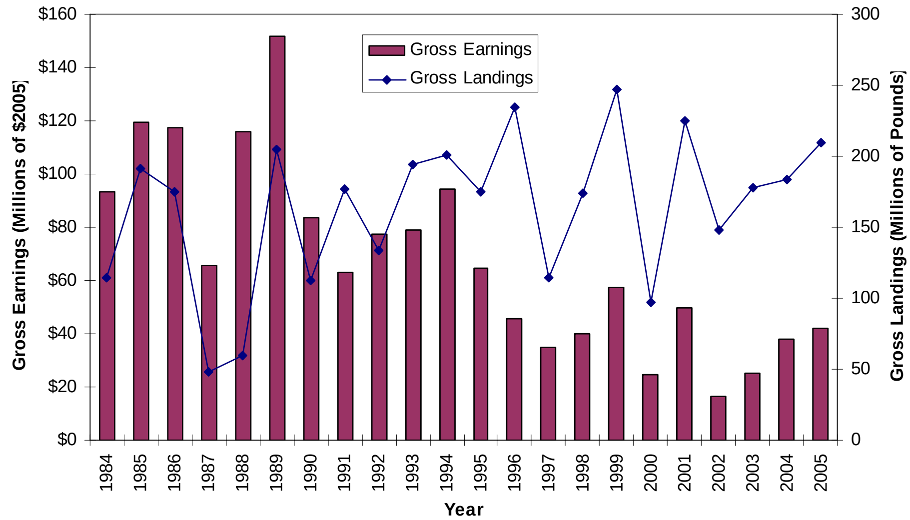
Source: Bachman et al. 2005

Based on estimated portions of each species originating from the Tongass National Forest, over 70 percent of the total harvested fish began their life in streams and lakes within the Forest boundaries. Fluctuations in commercial harvest trends are partly attributable to changes in ocean productivity. The productivity of marine waters in the Gulf of Alaska, and the survival of salmon and steelhead trout, is both highly variable and cyclic. From the mid-1970s into the mid-1990s, favorable ocean currents have resulted in high productivity and, consequently, high marine survival of salmon (USDA Forest Service 1995a). These favorable conditions have been more variable in more recent years and may not be following past cyclic patterns (Kruse 1998).

Based on the estimate of salmon produced from streams originating in the Tongass National Forest, estimated annual commercial salmon harvest (1984 to 2005) averaged over 164 million pounds, with a wholesale value (ex-vessel value) over $68 million (adjusted to 2005 dollars). The harvesting and processing of these salmon provided a substantial number of direct and indirect jobs in Southeast Alaska. In the most recent year reported, 2005, more than 210 million pounds of salmon were harvested worth more than $41 million in Southeast Alaska (Figure 3.6-3)

Hatchery production has also contributed substantially in overall fish production regionally. Hatchery production state-wide has greatly increased since 1977 with releases of more than 1 billion fish occurring annually since 1988, peaking in 2003 with more than 1.6 billion juvenile fish released state-wide (White 2006). These hatchery-released fish have contributing substantially to harvest statewide, with the number of returning fish increasing from less than 5 million in 1980 to more than 80 million statewide in both 2003 and 2005. A substantial portion of hatchery

Figure 3.6-3
Commercial Harvest and Wholesale (Exvessel) CPI Adjusted Value of Salmon Produced from the Tongass National Forest, Southeast Alaska (1984-2005)



Data Sources: Don Martin, Personal Communication, July 2006: Backman et al. 2005,http://www.cf.adfg.state.ak.us/geninfo/finfish/salmon/catchval/blusheet/94exvesl.php;http://www.cf.adfg.state.ak.us/geninfo/finfish/salmon/catchval/history/1970-2004s.php, Duffy (2004) http://www.cf.adfg.state.ak.us/geninfo/pubs/csepseak/csepseak.pdf

production and harvest occurs in Southeast Alaska with juvenile salmon releases equaling about one-third of total state release in 2005 (White 2006). Harvest of hatchery fish is a substantial portion of total salmon harvest in the Southeast Alaska region, averaging about 13 percent of the total number of commercially harvest fish (including cost recovery harvest) in recent years (1994 to 2005), or about 12 million fish annually (Alaska Department of Fish and Game [ADF&G] 2004a, White 2006). In some recent years, over 90 percent of the total commercial harvest of chum salmon, and a lesser percentage other salmon species, have resulted from enhancement projects in Southeast Alaska (ADF&G 2004a).

Approximately 85 percent of Southeast Alaska's sport fishing occurs in the vicinity of the Tongass National Forest. Sport fishing use has increased over the last four decades. For example, sport harvest of salmon in Southeast Alaska more than doubled in the last decade (from 1995 to 2004) (ADF&G 2004b). The economics of commercial and sport fishing is discussed in detail in the 1997 Tongass Forest Plan Revision Final EIS (USDA Forest Service 1997a) and updated in the *Economics and Social Environment* section of this chapter.

Fish Habitat

With more than 42,700 miles of streams and 250,000 acres of ponds and lakes (based on GIS measurements), the Forest provides abundant fish habitat. The habitat has been inventoried and classified, and estimates have been made of fish production. This section begins with a description of key habitat components, then presents a review of information on the effects of past harvest in Southeast Alaska on salmonid stocks, and finishes with a description of how fish habitat is mapped and classified on the Tongass.

Important Components of Fish Habitat

Stream Temperature and Dissolved Oxygen

Salmon and trout have optimum temperature ranges for rearing, spawning, and adult migration. Generally salmonid require cool stream temperature to thrive in most stream conditions (Bjornn and Reiser 1991). While very cool water conditions can be a limiting factor to salmon and trout survival and production, warmer temperatures are most often the more limiting condition within most of the range of Pacific salmon. However, in much of Southeast Alaska, increased summer temperature is much less of a concern than for more southerly regions due to the normal cool climatic conditions (Murphy and Milner 1997). Heating of streams also affects the amount of dissolved oxygen in the water, another important component for salmonid production and survival.

Stream temperatures are affected by solar radiation, evaporation, advection, conduction, and convection (Adams and Sullivan 1989, Brown 1983). Streams have a general tendency to warm as flow moves from upstream to downstream. The natural heating from solar radiation, increased air temperatures, and natural decreased stream flow tend to result in higher temperatures in the summer (Zwieniecki and Newton 1999). Timber harvest can have its greatest effect on stream temperature by removal of shade trees that reduce direct solar heating. Increased temperature results in reduced oxygen, but other factors such as decaying organic matter or abundance of salmon in a stream can also have large effects on dissolved oxygen concentrations (Pentec Environmental 1991, Welch et al. 1998, Spence et al. 1996).

Lack of stream shading buffers has been found to cause increases in stream temperature over 10 degrees Celcius (°C) in some small streams of the Pacific Northwest (Everest and Reeves 2007). Additionally lack of buffers can result in elevated microclimate temperatures that contribute to this heating (Spence et al. 1996, Chen 1991, Chen et al. 1992, Sullivan et al. 1990). However, effects in Southeast Alaska on stream temperature from past and resent harvest have not been of this magnitude and are often not significantly different than similar unaffected streams.

Murphy and Milner (1997) summarized the results of many of the studies on effects on stream temperature, of earlier past harvest in Southeast Alaska, when streams were typically not buffered. They noted a wide range of results. Some very small streams with timber harvest approached lethal levels (over 25°C). But most studies found no effect or only modest (e.g., 2°C) increases with stream temperatures not approaching lethal levels. These studies were all on streams that were harvested under old rules that did not require buffers. Effects on winter temperature also showed varied results in Southeast Alaska, some ranging from a slight increase, to no change, to a slight decrease in temperature in streams traversing clearcuts (Meehan et al. 1969 and Thedinga et al. 1989). Recent watershed monitoring on the Tongass (1997 to 2002) found that state water temperature standards were exceeded at similar rates in both harvested and unharvested watersheds (Walters and Prefontaine 2005). This suggests that elevated summer stream temperature is affected more by other environmental conditions than past timber and riparian harvest.

Situations where elevated temperature and low dissolved oxygen have been found to occur, and associated with fish die-offs, have been related mostly to the characteristics of stream morphology, hydrology, season, and number of fish present, not past timber harvest (Pentec 1991, Murphy 1985, Murphy and Milner 1997). Generally small basins of low elevation, low stream flow, confined intertidal conditions, with high numbers of adult fish, during warm weather periods were areas that occasionally had die-offs of adult salmon due to low oxygen (Murphy and Milner 1997).

Sediment

Sediment, includes both the coarse (gravel, cobble, bolder, bedrock) and fine (sand, silt) substrate composition in the stream channel. The relative composition affects many factors in stream production, including spawning areas and spawning success for salmon and trout, and benthic organism composition, which is an important food resource for fish. The amount of coarse sediment affects available spawning habitat and influences pool filling and bank stability (Spence et al. 1996). High levels of fines also affect pool filling, but also greatly influence survival of eggs and fry in spawning nests of salmon and trout (Chapman and McLeod 1987, Chapman 1988, Iwamoto et al. 1978, Gregory and Bisson 1997, McNeil 1964). Generally, the greater the portion of fines in spawning areas, the lower the survival of eggs and fry (McNeil 1964, Koski 1972, Chapman 1988). Increased fines in streams also reduce interstitial spaces in large substrate that are important habitat for many common cool water mountain stream aquatic insects.

Sources of sediment include input from banks, downstream movement from tributaries, and slumping and slides that enter or are near streams. The stream bed composition is a function of stream slope, roughness elements (e.g., amount and size of large woody debris [LWD]), and local adjacent geomorphic composition.

Several timber harvest related activities may affect stream substrate composition, including road construction, road drainage structures, level of use and maintenance of roads, number of stream crossings by roads, density of roads in the watershed, erosion and slumping of hill slopes following harvest, bank erosion where trees have been removed, and hydrology changes (Swanson et al. 1987, Furniss et al. 1991, Spence et al. 1996, Everest et al. 1987).

Past timber harvest practices have affected sediment levels in Southeast Alaska streams in some situations (Pentec 1990, Murphy and Milner 1997). Timber harvest in other regions have produced substantial increases in sediment and changes in composition; these are generally related to intensive timber harvest activities (Holtby and Scrivener, 1989, Cederholm et al. 1981). However, many studies of the effects of timber harvest and amount of sediment in Southeast Alaska streams have been inconclusive (Murphy and Milner 1997, Sheridan et al. 1984). Nevertheless, models developed by the Forest Service suggest that timber harvest activities, especially related to road construction, would increase fine sediment inputs to streams potentially affecting spawning success (Murphy and Milner 1997).

Large Woody Debris

LWD in stream channels includes entire trees, rootwads, and larger branches. LWD is an important component of fish habitat for good trout and salmon habitat, especially in heavily wooded regions (Swanson et al. 1976, Bisson et al. 1987, Naiman et al. 1992, Beechie and Sibley 1997, Spence et al. 1996, Murphy et al. 1986). LWD provides channel complexity, cover, and is especially important in the formation of pools (Bisson et al. 1987, Sullivan et al 1987, Benda et al. 2003). LWD has been found to form over 70 percent of all pools in a typical Alaskan valley bottom stream (Heifetz et al. 1986). The benefits of LWD in streams include critical sediment retention (Keller and Swanson 1979, Sedell et al. 1988), structural diversity (Ralph et al. 1994), gradient modification (Bilby 1979), nutrient production (Cummins 1974), and protective cover from predators. Its presence is often critical for overwinter habitat for various salmon and trout (Murphy and Milner 1997, Murphy et al. 1985, Koski et al.1984). Wood controls sediment movement downstream, minimizing the risk of debris flows in small headwater streams. In large streams, coarse sediment accumulated behind LWD often provides spawning gravels (Bilby and Bisson 1998, Montgomery et al. 2003). Newly entered LWD plays an important role in stream by providing inputs of leaf litter and needles and as it ages enhances nutrient dynamics.

Sources of LWD to streams include a variety of processes such as windthrow, wildfires, stream bank erosion, tree natural mortality, and debris slides, deep-seated mass soil movement, and input from upstream areas (Swanson and Lienkamper 1978, Benda et al 2003). Small headwater streams can provide wood to larger channels downstream (Potts and Anderson 1990, Prichard et al. 1998, Coho and Burges 1991, Benda et al 2003, Reeves et al. 2003).

Debris flows and dam-break floods during high flow occurrences can cause the transport of wood from upstream to downstream regions (Swanson and Lienkaemper, 1978). Because of the large size of much of the wood that enters streams, its ability to float during this type of event is limited to larger third- to fifth-order streams (Swanson and Lienkaemper 1978). While much less frequent than high flow events, large amounts of LWD can be added by debris torrents (Lamberti et al. 1991). The entry of LWD and coarse sediment at tributary junctions by debris torrents can form complex habitat, including pools and cover, and add spawning gravel to the main channel (Benda et al. 2003).

In streams of the Tongass, Murphy and Koski (1986) found that 40 percent of LWD in streams originated within 3 feet of the bank and 99 percent within 100 feet of stream channel. Martin et al. (1998) found similar results estimating that 94 percent of LWD entered streams in unharvested Southeast Alaska areas originated within 98 feet of the stream channel. There may be exceptions to this in certain streams. Reeves et al. (2003) found that about 65 percent of the LWD pieces in Oregon coastal streams originated in upslope areas, primarily from steep intersecting stream channel. Reeves et al. (2003) noted that similar conditions were observed in California and Washington states. The width of the stream valley and the slope of intersecting tributaires were the main factors determining the portion of wood entering from side streams.

The primary timber-related actions that may affect LWD supply to streams include buffer width along streams, stream class and channel characteristics that buffers are placed on, size of trees remaining in the buffer area, and effects on windthrow from adjacent harvest.

Murphy and Koski (1989) used a model to estimate that for moderate-sized valley bottom streams in Southeast Alaska with no buffers, LWD would decrease to about 30 percent of pre-harvest levels in about 90 years. Some studies have documented reduced LWD in Alaska clearcut streams relative to old-growth stream channels over time (Heifetz et al. 1986, Johnson et al. 1986, Murphy et al. 1986, Murphy and Milner 1997). But in the short term, LWD may be higher in clearcut areas (Lisle 1986). Limited long-term monitoring has occurred on Southeast Alaska streams to document changes. However, it was found that Maybeso Creek had a decrease in number and size of LWD, 30 years after harvest (Bryant 1980) with similar changes in Harris River (Bryant 1985, cited in Murphy and Milner 1997). However, these watersheds were intensively logged under conditions that had no buffer strips on streams; buffers were almost completely absent during timber harvest until the late 1980s. Buffer strips have greatly increased in frequency and size since then.

Buffer strip blowdown affects timing of LWD entry to streams. Several studies have shown that blowdown in buffers increases after harvest, primarily in the short term

(Pentec 1996, Martin 1996). Effects were short term, however, with rate of blowdown decreasing over time and the effects on total LWD loading to streams slight. There has been some documentation of a large increase in rootwads in a stream due to blowdown, which was considered beneficial to fish habitat (Murphy and Milner 1997). Recent monitoring of harvest areas since 2000 have found highly variable rates and amounts of windthrow adjacent to harvest units, but effects on stream LWD supply was not assessed (USDA Forest Service 2007). However, Martin and Grotefendt (2007) found that windthrow on non-NFS lands with 20-meter buffers would, on average, reduce the long-term LWD supply in Southeast Alaska forest streams by about 5 percent relative to unharvested areas (an additional 5 percent would be lost due to harvest).

Food Sources

Food sources for stream fish can originate directly within the stream or enter from the adjacent terrestrial environment or upstream aquatic environment. The main sources are from leaf and litter deposits from the adjacent riparian vegetation, algae growth and production on the stream bottom, and from returning salmon carcasses. This is ultimately the food base for smaller aquatic organisms (e.g., aquatic insects) that become food sources for stream fish. Detrital input is the main source from heavily shaded small- and medium-sized streams (Richardson 1992, Gregory et al. 1991). Larger streams in contrast derive much more of their food sources from algae production. Nutrient and organic input from returning salmon are also important (Wipfli et al. 1998). Small streams, many of which are not fish-bearing, supply nutrients that contribute substantially to larger streams (Independent Multidisciplinary Science Team 1999). When riparian trees are removed, the primary source of food is initially shifted to algae production within the stream and is derived less from leaf and needle organic matter (Murphy and Milner 1997). Overall production along many streams with canopy removal in Southeast Alaska actually increased (those where light was limiting), while in some there was no change (Murphy and Milner 1997). When second-growth areas regrow, however, production may be reduced due to shade greater than was produced by the original old growth. Small streams in Alaska have been found to also contribute substantially to larger streams through downstream transport of terrestrial and aquatic prey directly and detritus resources indirectly for fish (Wipfli 1996, Wipfli and Gregovich, Piccolo and Wipfli 2002). The type of riparian forest along these small streams affects both the amount and type of resources passed down stream. In some cases, the regrowth of alder trees along streams following harvest has resulted in higher amount of resources to downstream fish streams (Piccolo and Wipfli 2002). While changes to riparian areas will change the composition of the downstream transported food sources, the final overall effect of total removal, or complete retention of riparian vegetation on fishless streams on downstream fish streams over the long term is not clear, as actions near these small stream may have additional effects (e.g. sedimentation) on stream production (Wipfli and Gregovich 2002).

Effects of Past Forest Management Practices on Salmonid Fish Stocks

Past timber harvest practices and related actions in many regions of native Pacific salmon distribution range have been associated with declines of fish stocks (Everest and Reeves 2007). Similar reductions in stocks, however, have not been observed in Alaska (Byrant and Everest 1998). This may be partly because other human-induced disturbances (e.g. agriculture, dams, urban development), which are common in other regions, are rare in Southeast Alaska. As noted above, older forest practices (mostly prior to 1980) in the Tongass National Forest have had documented adverse effects to anadromous fish habitat conditions, including spawning habitat, rearing habitat, and migration conditions (Murphy and Milner 1997). Harvest during this timeframe accounts for about 60 percent of all timber harvest on the Tongass National Forest (see Tables 3.9-8 and 3.9-9 in the *Biodiversity* section). In one study of multiple streams in Southeast Alaska, summer fry numbers of coho salmon increased in clearcut areas, but had reduced or similar numbers of fall and winter stages of juveniles relative to old-growth systems (Murphy et al 1986). In another study, increased summer abundance of coho juveniles in clearcut areas had reduced the number of outmigrating coho smolts relative to old-growth areas (Thedinga et al. 1989). Similarly, juvenile steelhead abundance, while high in unbuffered clearcut streams in the summer, became very low in the winter as these fish moved to buffered and old-growth habitats where cover was higher (Johnson et al. 1986).

However, studies addressing potential long-term effects of timber harvest and related actions on actual numbers of fish produced are rare within the range of Pacific salmon, including Alaska (Brant and Wright in press). Brant and Wright (in press) compiled and analyzed the data from multiple juvenile fish studies in 26 streams in Southeast Alaska in an attempt to determine what long-term effects past harvest management actions have had on fish production by comparing fish abundance in managed and old-growth watershed streams. The managed watershed all had timber harvest activity prior to 1980, which generally included clearcutting of riparian trees. Partly because most studies examined were not specifically designed to address long-term effects, overall results of this analysis were limited. They examined population densities of juvenile fish from studies conducted from 1978 to 2000, including data on coho salmon, Dolly Varden char, steelhead, and cutthroat trout. Even with the variability of data, they found statistically significant differences between the managed and old-growth watersheds. Coho salmon and Dolly Varden densities were significantly lower in harvested areas, while steelhead density was greater in harvested areas. Where long-term trends were significant, they were downward in harvested areas. There were many differences in overall production among regions, differences between seasons, and morphological differences among streams that contributed to much overlap in abundance between treatment groups and the lack of clear results. Overall, this study suggests some negative effects on some populations from older harvest practices (prior to 1980). New forest practices in the Tongass National Forest are intended to prevent the habitat degradation in riparian areas and headwater streams that have contributed to these adverse effects on populations (Bryant and Wright in press).

Recent monitoring of stream fish populations, based on specific sampling designs intended to assess effects of recent timber harvest practices, is not at the stage where determinations can be made about effects of these newer practices on fish populations (USDA Forest Service 2007), but, as shown earlier (Figures 3.6-1, and 3.6-2), overall trends in Southeast Alaska commercial harvests from 1960 to 2005, including coho, pink, chum, and sockeye salmon, do not indicate specific downward trends in these populations, or specific trends that could be correlated with amounts of timber harvest activity. While many factors outside of forest management practices in Southeast Alaska (e.g., ocean conditions, weather, hatchery releases, harvest management, watershed conditions in other areas) influence these numbers, no obvious effects can be discerned from harvest data. However, the effects of these moderating factors may be too great to permit harvest data to demonstrate any effects on fish populations resulting from timber harvest in specific Southeast Alaska watersheds, particularly if they are relatively small (Bryant and Wright in press, Bryant and Everest 1998).

Stream Classification on the Tongass

Fish habitat on the Tongass is classified, for management purposes, using two classification systems (see the *Water* section of this chapter). The first is stream class, which relates primarily to presence or absence of fish, type of fish, and water quality. The second category is stream process group, which characterizes streams based on channel and drainage basin morphological conditions.

Stream Class Inventory

Streams are categorized by stream class, a classification primarily associated with fish use. Stream classes describe stream values, such as whether anadromous or resident fish inhabit a particular stream. Class I streams are anadromous and high-value resident fish streams, Class II streams are other resident fish streams, Class III streams are managed for water quality and, where appropriate, downstream aquatic resources, and Class IV are small streams that do not influence downstream water quality or fish habitat. Refer to the *Water* section for more detailed descriptions (also see the *Glossary* in the Proposed Forest Plan volume for more complete definitions.)

Channel Type Inventory

Perennial and many intermittent streams on the Forest have been inventoried for channel-type. The channel types provide a system to estimate the amount and quality of fish habitat, and can be used to predict their physical response and sensitivity to different management activities. Channel types have been categorized into distinct groups, called “stream process groups.” Process groups describe the interrelationship between watershed runoff, landform relief, geology, and glacial or tidal influences on fluvial erosion or depositional processes. They are described in Channel Type User Guide Tongass National Forest Southeast Alaska (Paustian et al. 1992). Process groups, in conjunction with stream class, are used for assigning the Riparian Standards and Guidelines. The estimated miles of stream by process group and class within the Tongass National Forest are shown in Table 3.4-1 in the *Water* section of this chapter.

Fish Habitat Enhancement

Much emphasis has been placed on the enhancement of fish habitat on the Tongass National Forest. From 1980 to 1995, the Forest Service implemented 176 fisheries habitat enhancement projects on the Tongass (USDA Forest Service 1997a).

Many of the fish habitat enhancement projects implemented on the Tongass National Forest are cooperative projects involving multiple agencies and organizations, including the Forest Service, ADF&G, Regional Aquaculture Associations, timber companies, and other non-profit hatcheries.

Types of enhancement projects have included:

- Fishways
- Falls Modification
- Spawning Channels
- Debris Removal
- Lake Fertilization

- Lake Stocking
- Stream Stocking
- Rearing Ponds
- Incubation Boxes
- Large Woody Debris (LWD) Management

In more recent years, emphasis has included a reduced array of projects across the Forest. Specific ongoing projects include the following:

- Fishways: Currently one is actively being developed at Snow Pass Creek;
- Falls Modification: One site is being evaluated at Kanalku Creek;
- Spawning Channels: One new site is being evaluated at Fish Creek;
- Lake Fertilization: Currently one lake (Redoubt) is being fertilized annually;
- Lake Fish Stocking: One pen-rearing/lake stocking site is planned for implementation in 2007 at Bakewell Lake; and
- LWD: Several LWD projects are being implemented associated with watershed restoration.

Additionally, habitat access to streams has been improved through replacement of culverts that did not meet current juvenile fish passage design criteria. About 88 percent of all stream crossings (about 80 percent of the crossings are culverts or similar structures) have been assessed as to suitability to ensure juvenile fish passage. Among the crossings assessed, about 1,200 crossings, or 37 percent of all crossings (mostly culverts), did not meet current juvenile fish passage standards (USDA Forest Service 2006b). Of those not meeting standards, more than 75 percent were on Class II streams. Habitat above the crossings with potential passage problems was estimated to equal about 0.5 percent and 3.2 percent of all Class I and Class II stream miles on the Tongass, respectively. Based on the restrictive criteria used to determine whether a culvert is suitable for juvenile fish passage, the known distribution of fish above culverts designated as not meeting passage criteria (about 85 percent of those reaches have fish populations), and the small size of most of these streams, the habitat area affected would actually be much less than the percentages imply (USDA Forest Service 2006b). However, even though the habitat area may be small, the effect on an individual stock may be important. Most of these culverts were installed prior to implementation of the 1997 Forest Plan standards and guidelines for culvert installation. A recent survey of 29 culverts installed since the 1997 standards and guidelines began to be implemented found that two (7 percent) did not meet current juvenile fish passage criteria (Dick Aho, USDA Forest Service Biologist, Personal Communications August 23, 2007). To reduce these effects, culverts are being replaced, removed, or bypassed.

Approximately 240 culverts have been replaced through 2006 to improve fish passage. The Tongass National Forest estimated that it spent $1.5 to $2.0 million a year for culvert replacement for approximately 50 sites per year through 2005 (USDA Forest Service 2006b). The culvert replacement program declined in 2006 due to funding reductions, and is projected to continue to decline in future years. However, the intention is to continue this program of culvert replacement when funding supply is reinstated as part of road maintenance funding.

Fisheries Habitat Enhancement Opportunities

The anticipated salmon production from fish habitat enhancement projects on the Tongass National Forest is calculated based on site-specific habitat conditions and an analysis of limiting factors for salmon production. The test for these habitat production estimates consists of monitoring conducted on individual projects and the subsequent feedback of the monitoring results into the project planning process.

The 1997 Tongass Land Management Plan Revision Final EIS identified 158 potential projects for initiation during the first 10 years of implementation of the Forest Plan (USDA Forest Service 1997a). The extent of implementation of these projects has been considerably less. The public continues to expect the maintenance or improvement of fish habitat values. Public interest for subsistence, commercial, and sport-harvested fish remains high.

Demand for subsistence fish is discussed in the *Subsistence* section of this chapter, while commercial and sport fish demand are reviewed in this section. Commercial fish demand is calculated based on goals set by Regional Salmon Planning Teams for annual fish production for several species. Some of the “year 2000” goals were set in 1981 in the Comprehensive Salmon Plan for Southeast Alaska, Phase I, and have not been updated. Annual common property commercial harvest usually achieved these goals for pink salmon (92 percent), coho salmon (61 percent), and sockeye salmon (58 percent), but infrequently for chum salmon (31 percent) for the period of 1991 through 2003 (ADF&G 2004a). Harvest has been highly variable during this period. National Forest habitats were estimated to contribute approximately 80 percent of the fisheries in Southeast Alaska (USDA Forest Service 1997a), although the relative contribution has decreased in more recent years due to increased hatchery production.

There has been a tenfold increase in state-wide angler participation from 1961 through 2004, with total license sales in Alaska increasing from 55,564 to 503,422 during this period (Jennings et al. 2007). Overall, the number of anglers increased in Southeast Alaska by about 40 percent between 1991 and 2004 (from about 93,000 to 130,000 angler licenses) (Howe et al. 1995, Howe et al. 2001, Jennings et al. 2006, 2007). This equates to about a 4.5 percent increase in total licenses sales in Southeast Alaska annually. However, the number of Southeast Alaska resident anglers declined slightly since 1991 (about 10 percent), while the number of non-resident anglers increased from about 58,000 to 98,000 between 1991 and 2004; a 70 percent increase. The rate of increase exceeds that for sport fishing participation in all of Alaska for this same period (1991 to 2004) with total state fishing license sales increasing about 29 percent (from about 391,000 to over 503,000) (Jennings et al. 2007).

Fish Management Indicator Species

National Forest Management Act (NFMA) regulations direct the use of Management Indicator Species (MIS) in forest planning to help display the effects of forest management. MIS are species whose population changes are believed to indicate the effects of land management activities. For the 1997 Forest Plan, pink salmon, coho salmon, Dolly Varden char, and cutthroat trout were selected as MIS. Pink salmon were selected to represent anadromous fish that are limited in their freshwater life period by spawning gravel quality and quantity; coho salmon to represent anadromous fish that are generally limited in their freshwater life period by stream and lake rearing area; Dolly Varden char because of their ubiquitous distribution in freshwater habitats; and cutthroat trout because of their dependency on small freshwater stream systems, which are most susceptible to effects from management activities. These MIS fish species, and their habitats, are described in the 1997 Forest Plan Revision Final EIS.

Threatened and Endangered Fish Species

Federally listed threatened and endangered species are those plant and animal species formally listed by the U.S. Fish and Wildlife Service (USFWS) or the National Marine Fisheries Service (NMFS), under authority of the Endangered Species Act (ESA) of 1973, as amended. An endangered species is defined as one that is in danger of extinction throughout all or a significant portion of its range. A threatened species is defined as one that is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range.

No federally listed fish species or stocks originate from Alaska streams. However, some federally listed fish stocks may occur in marine waters within the boundary of the Tongass National Forest. These fish include the following:

Endangered species:

- Snake River sockeye salmon
- Upper Columbia River spring-run Chinook salmon
- Upper Columbia River steelhead

Threatened species:

- Snake River spring/summer Chinook salmon
- Snake River fall Chinook salmon
- Puget Sound Chinook salmon
- Lower Columbia River Chinook salmon
- Upper Willamette River Chinook salmon
- Columbia River chum salmon
- Snake River Basin steelhead
- Lower Columbia River steelhead
- Upper Willamette River steelhead
- Middle Columbia River steelhead
- Puget Sound steelhead

These listed stocks of salmon and steelhead do not spawn in Alaska, but are known to seasonally inhabit marine waters on the outside coast to the west and occasionally in inside waters of the Tongass National Forest. They may feed on fish that are dependent on coastal marine waters of the Tongass National Forest at some stages of their lives.

Pursuant to Section 7 of the ESA, a biological assessment was prepared to assess the effects of the 1997 Forest Plan revision on the endangered Snake River sockeye salmon and the threatened Snake River spring/summer Chinook salmon and Snake River fall Chinook salmon, and submitted to NMFS for review and concurrence in the Tongass Forest Plan process (Appendix J of the 1997 Tongass Forest Plan Revision EIS). This assessment has been updated to address the currently listed fish species relative to the alternatives considered in the Forest Plan amendment (Appendix F).

Essential Fish Habitat

The *Magnuson–Stevens Fishery Conservation and Management Act* mandates that agencies initiate consultation with NMFS for any activities that could affect essential fish habitat (EFH). EFH has been broadly defined by Congress for federally managed species to be "those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity".

NMFS (2005) clarified what the specific definition is for EFH in Alaskan waters. EFH is the general distribution of a species described by life stage. It is generally the habitat area that includes 95 percent of that life stage, where it is known, to occur. Where distribution data is unknown, surrogate species may be assumed. Maps were presented in NMFS (2005) defining EFH for species and life stages; other than for salmon species, little EFH is present in the inside waters of Southeast Alaska. Those groundfish species that are present include some sole species life stages only. Several other species, however, have some life stages located in the marine waters offshore of Southeast Alaska and some enter outer nearshore waters. In general, EFH for marine groundfish species (e.g., rockfish, sablefish, sole, plaice, cod, pollock), are extremely limited near Tongass waters.

Salmon EFH covers freshwater, estuarine, and marine waters from the high tide level to 200 meters deep and out to the 200 nautical mile U.S. exclusion zone, depending on life stage. The freshwater EFH is defined primarily by what is present in the ADF&G's Catalogue of Waters Important for Spawning, Rearing, or Migrations of Anadromous Fishes (ADF&G 1998). Freshwater EFH for salmon in the Tongass would include all streams, lakes, ponds, and wetlands currently or historically accessible to salmon. The shallow marine waters adjacent to forest lands are considered EFH for salmon, but little of this area is EFH for most groundfish species.

Sensitive Fish Species

Sensitive species are those plant and animal species identified by the Regional Forester for which population viability is a concern on National Forest Service (NFS) lands within the region. The goal of the Forest Service Sensitive Species Program (Forest Service Manual 2670) is to ensure that species numbers and population distribution are adequate so that no federal listing will be required and no extirpation will occur on NFS lands.

The Alaska Region Sensitive Species List was updated in June 2002. There are three fish species currently designated as sensitive species in the Alaska Region.

Northern Pike

Northern pike are found in five lakes, referred to as Pike Lakes, approximately 23 miles east of Yakutat in Roadless Area 341 (Browning 1986). These lakes are shallow, with high concentrations of humic acid and peat-filled margins. The northern pike in Pike Lakes are the only naturally occurring pike in Southeast Alaska and are probably remnant populations that survived only because the most recent glacial advance missed the Pike Lakes area. Relatively little information is available on the life history and population dynamics of these pike populations. Their presence in any other regional waters would be considered as an invasive species (see the *Invasive Aquatic Species* subsection below).

Large Chum Salmon

Near Hyder on the Portland Canal, Fish Creek produces very large chum salmon, probably the largest chum salmon in North America. Several fish over 38 pounds have been weighed by biologists; fish weighing 25 pounds are common. The average size of large chum salmon is close to 20 pounds (the average chum salmon from other areas weighs around 10 pounds). A high percentage of the returning fish have spent 4 and 5 years in the ocean, accounting for the large average size. Normally, chum salmon stay at sea for 2 to 5 years (Salo 1991). Fish Creek is a low-gradient stream, dominated by high-quality spawning gravels and extensive areas of groundwater upwelling. The predominant upwelling and high-quality spawning gravels appear to be the reasons for the remarkable production levels. Populations have been stable or increasing, with a reported escapement of more than 60,000 in 1993.

Island Run King Salmon

King Salmon River and Wheeler Creek populations of king salmon are island genetic stocks. No other naturally occurring runs of island king salmon stocks are known to exist in Southeast Alaska. King Salmon River and Wheeler Creek are both within Kootznoowoo Wilderness. Information on these populations is limited, although recent escapement counts suggest the population is stable or slightly decreasing. The King Salmon River stock serves as an important king salmon transplant source for other streams and rivers.

Invasive Aquatic Species

Species are considered invasive if they are not native to an ecosystem, and if they are likely to cause harm to human health, the economy, or the environment (Executive Order 13112). Due to its remote landscape, northern climate, small human population, and few concentrated disturbed habitat areas, Alaska has relatively few invasive species compared to the rest of the United States, according to ADF&G's Alaska Aquatic Nuisance Species Management Plan (Fay 2002). However, factors such as altered disturbance patterns, constant flow of marine-based shipping and cruise ships, fishing and recreational boating traffic, and climate change may increase the prevalence of invasive aquatic species. Global climate change may create conditions suitable for new invasives, as well as range expansions, by altering geographic range limits and making habitats no longer as suitable for existing native species.

Invasive aquatic species can affect native species by eating them, competing with them, hybridizing with them, disrupting or destroying their habitat, or introducing pathogens or parasites that sicken or kill them (Schrader and Hennon 2005). In addition to natural range extension, several potential pathways exist for introduction of invasive aquatic species. These pathways included fish farms, international and local movement of bait and game fish, trade in live seafood, aquaculture, and contaminated sport angle gear brought into Alaska, as well as ballast discharge from international vessels (Fay 2002, Schrader and Hennon 2005). Several aquatic species have been noted as potential threats to Alaska, including fish (northern pike, Atlantic salmon, yellow perch, ornamental aquarium fish), invertebrates (green crab, New Zealand mudsnail, Chinese mitten crab, zebra mussel, signal crayfish, spiny water flea), plant (cordgrass), and several additional miscellaneous taxa (Fay 2002, Schrader and Hennon 2005). Additionally, eastern brook trout (non-native) and non-endemic rainbow trout have been stocked in many areas where they were not native and compete or hybridize with native trout (Schrader and Hennon 2005). Of these fish, transplanted northern pike and Atlantic salmon are the two fish species of greatest concern (Fay 2002). The invertebrates Chinese mitten crab, green crab, and New Zealand mudsnail, even though they have not been found in Alaska, are of major concern because of their potential to do serious damage to the Alaskan ecosystems (Hines et al. 2004, Schrader and Hennon 2005). Atlantic salmon that have escaped from fish farms pose a threat to native salmon by competing for habitat and introducing diseases and parasites. This species has been observed in Southeast Alaska marine waters and, rarely, in streams (Fay 2002). Also, northern pike, which has not appeared in Southeast Alaska (with the exception of a native stock in Yakutat), have caused widespread damage to resident trout where they have been introduced, and could potentially affect coho salmon through predation. Northern pike have the potential to cause serious environmental and economic damage to highly productive salmon streams in Southeast Alaska (Fay 2002). In the Tongass, there is a risk that these and possibly other non-native sport fish may be introduced into lakes and rivers by individuals seeking to increase sport fishing opportunities. As the road network is extended into more areas of Southeast Alaska, this risk increases. Refer to the ADF&G aquatic species management plan for additional details.

Environmental Consequences

Direct and Indirect Effects

Many of the standards and guidelines in the current Forest Plan were based, to a large extent, on the recommendations of the Anadromous Fisheries Habitat Assessment (AFHA) (USDA Forest Service 1995a). AFHA is considered the most comprehensive scientific review available for the Tongass. The 1997 ROD notes that the standards and guidelines and other direction included in the current Forest Plan meet or exceed all of the recommendations by AFHA. The AFHA evaluation is still relevant for the current EIS.

Additionally, two separate panels assessed effects of alternatives on fish-related issues (Dunlap 1996, 1997). The two panel assessments were completed, one in 1996, which was used for the 1997 EIS assessment, and a more limited assessment completed in 1997 that added additional panel assessments for a subset of the alternatives included in the 1997 EIS. While the current alternatives being evaluated have differences from the alternatives evaluated by these panels, four of them are based on the 1997 alternatives and differ only in specific ways. Where the similarities are comparable, the results of the assessments can be used to help evaluate relative effects of the considered alternatives.

The panel assessments were based on activities that are part of timber management among the alternatives. The main activities included roads and harvest. The location and amount of road miles have historically affected slope stability and runoff to steams having major effects on water quality and fish passage, which are both factors that affect fish habitat and abundance. Additionally, the location and amount of timber harvest can affect riparian vegetation and slope stability, especially on unstable soils, which also have substantial influence fish habitat. These two items, as well as aquatic habitat enhancement, will be discussed first under General Effects. They will set the stage for the discussion of how the alternatives compare to the past panel assessments. The Fish/Riparian Assessment Panel summary reports (Dunlap 1996, 1997) serve as the basis for the second part of the following discussion of environmental consequences.

In general, with the exception of Alternatives 4 and 7, the effects of all alternatives on fish resources are expected to be at or below those predicted for the selected alternative in the 1997 Tongass FEIS, which represents the current Forest Plan. The Forest Plan is very similar to Alternatives 5 and 6.

General Effects

Roads

Roads pose the greatest risk to fish resources on the Tongass (Dunlap 1996, USDA Forest Service and U.S. Department of the Interior (USDI), Bureau of Land Management 1995), partly because they pose the largest risk of management-caused sediment input to streams (Reid and Dunne 1984, Furniss et al. 1991, Gomi et al. 2005, Hassan et al. 2005). Roads can potentially create areas of hillslope instability resulting in landslide generation, contribute fine sediment from surface erosion, and alter surface and subsurface water flow patterns. Landslide debris (sediment, large wood) that enters streams may block or shift channels, fill pools, and increase fines in spawning areas. Increased sediment yield, including yields during road construction, road use during timber harvest activities, and lack of sufficient maintenance or proper closure following timber harvest activities, are all viewed as potential areas of risk for maintaining fish resources. Roads may also increase risk to fish movement due to improper construction relative to fish passage (Gibson et al 2005) and blocked culverts. Stream-rearing fish, particularly cutthroat trout and Dolly Varden, that occupy the smaller headwater streams during some parts of their lives are at the greatest risk. Juveniles of stream-rearing fish are often highly mobile during their freshwater stage, moving seasonally between stream reaches.

While riparian protection (e.g., buffers) can greatly reduce sediment delivery to streams (Belt et al. 1992, Chamberlin et al. 1991), they provide little reduction in the risks to fish or stream channels caused by roads during construction. Road construction practices require additional attention to ensure that risks to fish and stream channels are not excessively high. Roads also increase the risk that improved access would contribute to over-harvest of fish by anglers. These potential effects are best addressed at the site-specific level during project design.

USDA Forest Service and USDI, Bureau of Land Management (1995) concluded that watersheds with fewer roads generally have healthier fish populations. NMFS, as part of their working guidance document for comprehensive salmon restoration initiatives on the Pacific coast, developed a matrix of key habitat indicators of watershed conditions to determine where adverse effects may occur, and identify factors that limit salmonid production (NMFS 1996). NMFS indicted that these factors are appropriate for use at watershed, reach, and site scales. One of these habitat indicators was road density. NMFS noted the following: 1) a watershed with road density of less than 2 miles per square mile and no valley bottom roads would be considered “properly functioning,” 2) watersheds with road density of 2 to 3 miles per square mile and some valley bottom roads were “at risk,” and 3) watersheds with road density greater than 3 miles per square mile and many valley bottom roads were rated as “not properly functioning.” Based on this information, the frequency of occurrence of road densities exceeding the “properly functioning” value of 2 miles of road per square miles, not considering road location, was used as a general index of relative effects of roads on aquatic resources.

Total road miles and road density would increase under all alternatives and follow a similar pattern (Table 3.6-2). The increase in road miles over existing conditions could range from 16 to 118 percent for the alternatives over the next 100+ years. This percentage increase would be 16 to 57 percent for Alternatives 1, 2, and 3; 76 to 78 percent for Alternatives 5 and 6; and 99 to 118 percent for Alternatives 4 and 7. Currently, the Value Comparison Units (VCUs) containing at least some harvest account for about 41 percent of all VCUs on the Tongass; however, total harvest in each VCU is highly variable ranging from just a few acres to several thousand. Currently, the average road density on NFS lands on all VCUs is 0.19 mile per square mile, while the average road density in only VCUs with some past harvest is approximately 0.46 mile per square mile. After more than 100 years of Forest Plan implementation, the estimated overall road density on NFS lands would range from 0.22 mile per square mile under Alternative 1 to 0.41 mile per square mile under Alternative 7. On average, all of these densities are within the range of what NMFS (1996) characterized as “properly functioning” watershed road densities for west coast salmon. Currently, about 98 percent of all VCUs have road densities in the “properly functioning” range (less than 2 miles of road per square mile) for NFS lands. The alternatives would reduce the portion of VCUs with this road density on NFS lands to about 96 percent (Alternative 1) to 90 percent (Alternative 7) (Table 3.6-2). Alternatives 1 and 2 would have the lowest frequency of VCUs with road density over 2 miles per square mile. The largest relative increase in the percentage of VCUs with high road density would occur between existing conditions and Alternative 7. Additionally, the number of VCUs that have no roads on NFS lands is currently about 68 percent; this percentage would remain about the same under Alternative 1 and decrease to 60 to 66 percent under Alternatives 2, 3, and 6, and to 51 to 59 percent under Alternatives 4, 5, and 7. Increases in road densities are primarily in watersheds that already have roads. Potential effects that additional road construction and increases in density would have on any specific VCU and related watershed condition would ultimately be addressed on a project-specific level.

Table 3.6-2
Estimated Road Miles and Percent of VCUs in Road Density Categories on NFS Lands under Existing Conditions and after 100+ years of Full Implementation[1]

Road Type	Existing	Alternative 1	Alternative 2	Alternative 3	Alternative 4	Alternative 5	Alternative 6	Alternative 7
Existing Roads	4,941	4,941	4,941	4,941	4,941	4,941	4,941	4,941
New Road Construction	-	774	2,079	2,799	4,890	3,874	3,744	5,825

Total Roads	4,941	5,716	7,021	7,741	9,832	8,816	8,686	10,767
Percent Increase	-	16%	42%	57%	99%	78%	76%	118%
Road Density Categories (Mi /Sq. Mi.)[3]								
0	68.0%	67.8%	66.0%	63.6%	52.1%	58.9%	60.0%	51.4%
>0 - 1.0	21.5%	20.4%	19.4%	20.2%	26.1%	22.4%	21.1%	24.9%
>1.0 - 2.0	8.0%	7.3%	8.7%	9.3%	13.5%	11.0%	11.4%	13.5%
>2.0 - 3.0	2.0%	3.5%	4.8%	5.5%	6.6%	6.3%	6.1%	7.6%
>3.0 - 4.0	0.4%	1.0%	1.2%	1.4%	1.7%	1.4%	1.4%	2.5%
>4.0	0.0%	0.0%	0.0%	0.0%	0.0%	0.0%	0.0%	0.1%
Percent of VCUs with Average Road Density less than 2 miles/mi^2	98%	96%	94%	93%	92%	92%	93%	90%
Average Road Density (miles /mi^2) for all NFS Lands	0.19	0.22	0.27	0.30	0.38	0.34	0.33	0.41

[1] Assumes full implementation of Forest Plan at ASQ levels plus future non-NFS harvest. Includes adjusted road miles estimated to be needed to harvest all suitable timber in the alternative allowing for approximation of fall down (the reduction between the planned and the actual roads needed due to discovering additional streams, soils issues, etc, during timber sale layout). See Appendix B for details of estimating methods.
[2] Estimated existing road miles that would need to be reconstructed.
[3] Percentages are based on 935 VCUs that contain at least 100 acres of NFS lands.

It should be noted that these projected road densities are based on harvesting at the ASQ level, including both non-interchangeable components (NIC) I and II, over the next 100 years or so. Some adjustment has been made to the harvest acres to account for normal “fall down” that would result from actual on-the-ground surveys during layout when more streams, unsuitable soils, and other factors greatly reduce the actual amount of road and harvest that would occur on these lands. However, based on past harvest practices, even these adjustments may overestimate the future amount of harvest area, these road densities represent maximums and are not likely to be achieved.

Soils of high risk for landslide or mass wasting failure are those indicated as a mass movement index of 3 (MMI 3) (generally gradient of 55 to 72 percent). The upper ranges of these soils (65 to 72 percent) generally have the higher risk of slope failure. Those soils with slopes greater than 72 percent mass movement index of 4 (MMI 4) are removed from the suitable timber base, but may have small inclusions within the MMI 3 layer. Also, current standards and guidelines, in consideration of these concerns, recommend avoiding building roads on slopes greater than 67 percent. Therefore, roads built on soils with slopes greater than about 67 percent are considered at greater risk of slumping or mass failure, increasing the chance of large amounts of sediment entering streams. The miles of road likely to be constructed on soils of this type are shown in Table 3.6-3. While the area is small among all alternatives, due to standards and guidelines that restrict construction of roads in regions of this slope category, there are differences among the alternatives. Overall, Alternative 1 has the lowest portion of new roads in this category.

Table 3.6-3
Estimated Maximum Road Miles on Potentially Unstable Soils Based on Slopes Greater Than 67 Percent over the Length of the Project (approximately 100+ years)[1]

Road Type	Alternative						
	1	**2**	**3**	**4**	**5**	**6**	**7**
Road mile > 67% Slope	9	30	41	66	53	51	80

[1] Includes adjusted roads miles estimated to be needed to harvest all suitable timber in the alternative allowing for approximation of fall down (the reduction between the planned and the actual roads needed due to discovering additional streams, soils issues, etc, during timber sale layout).

Alternative 2 and 3 areas are also moderately low, while Alternatives 5 and 6 are intermediate and Alternatives 4 and 7 are the highest.

The number of road crossings of streams increases the risk of both adding sediment to streams and impeding fish passage (Class I and II streams). While the BMP for construction methods of culverts and bridges reduce these risk for sediment and turbidity, monitoring of some streams, which have mostly compliance with water quality standards, have found occasional increases in turbidity at least in the short term as described in the USDA Forest Service Tongass Monitoring Reports (USDA Forest Service 2004c). Also, new fish passage guidelines (Forest Service Handbook 2090.21 Aquatic Habitat Management Handbook as USDA Forest Service 2001a) for culvert design greatly reduce risk of new culvert installation impeding fish passage on Class I and II streams. But some risks still remain. An index of these risks to both added sediment from road crossings and impedance of fish passage is shown in Table 3.6-4. Currently about 3,600 fish stream crossings exist on the Tongass. The various alternatives would add moderately to this number increasing risk. Alternative 1 would have the least risk, while Alternatives 4 and 7 would have the most risk. Alternatives 5 and 6 would be similar, and intermediate. In general the trend follows that of road miles constructed.

Table 3.6-4
Estimated Number of Existing and Maximum New Stream Crossings for New Roads by Alternative over the Length of the Project (approximately 100+ years)[1]

Stream Class	Alternative							
	Existing[2]	1	2	3	4	5	6	7
I	1,300	47	137	193	377	296	293	472
II	2,300	121	293	389	769	621	603	958
III	-	650	1,783	2,371	3,917	3,186	3,093	4,899
Total	**3,600**	**817**	**2,213**	**2,952**	**5,064**	**4,103**	**3,989**	**6,328**

[1] Based on adjusted roads estimated to be needed to harvest all suitable timber in the alternative allowing for approximation of fall down (the reduction between the planned and the actual roads needed due to discovering additional streams, soils issues, etc, during timber sale layout). See Appendix B for details of estimation methods.
[2] Approximate estimate based on USDA Forest Service 2006 data. Values expanded based on portion of road miles assessed and known portion of Class I and II crossing in the Tongass. Class III stream crossing not assessed.

Timber Harvest

Timber harvest activities can increase risk to fish resources. Protection of riparian areas, including floodplains, areas of riparian vegetation, and certain wetlands associated with riparian systems are of particular concern. As discussed earlier, riparian vegetation serves many important functions for stream fish habitat, including supplying LWD, food input, and stream shade to name a few. Also of concern is the amount of protection afforded steeper channels (often not fish-bearing) in the headwaters areas and protection of steep hillslope areas. These streams (e.g. class III streams) also require LWD to properly function (Paustian et al. 2006), as well as contributing nutrients, food resources, and, in some situation, LWD to downstream fish streams. Protection of estuaries is also important when locating roads and timber harvest units. Although Forest Plan standards and guidelines associated with riparian areas, wetlands, and beach and estuary fringe are expected to protect fish resources from significant impacts associated with timber harvest, there is still some level of risk. The risk is related to the level of harvest, portion of streams in the harvest area, and quantity of potentially unstable slopes in the harvest area associated with each alternative.

Timber harvest activities on the Forest could potentially affect as many as 144,000 (Alternative 1) to 1,070,000 total acres (Alternative 7) after full implementation of the Forest Plan (100+ years) (Table 3.6-5). Alternatives 1, 2, and 3 would harvest the least acreage and Alternatives 4 and 7 the most, while Alternative 5 (No Action) and Alternative 6 (Proposed Action) would be in the higher portion of the intermediate range of alternatives. Projected acreages are based on harvesting at the Allowable Sale Quantity (ASQ) level, but with adjustment for probable fall down rates to account for reductions from on the ground surveys during project examination during specific project National Environmental Policy Act (NEPA) evaluation and final project layout. Therefore, the values are expected to reasonably approximate Forest-wide harvest (see the *Timber* section).

As harvested forest areas mature, young growth is predicted to become an increasingly larger portion of the harvest. When this occurs, the alternatives with lowest overall harvest have the highest portion of second-growth harvest reducing areas of new ground disturbance related to harvest. Alternatives 1, 2, and 3 would have at least 39 percent as young-growth harvest, while Alternatives 5 and 6 would have 33 percent. Altenatives 4 and 7 would have only 25 to 26 percent of the harvest as young growth. Actual acres of young growth would range from about 58,000 under Alternative 1 to 262,000 under Alternative 7.

Table 3.6-5
Estimated Maximum Acres of Timber Harvest after 100+ Years of Full Forest Plan Implementation[1]

Alternative	Maximum Acres Likely to be Harvested Over the Life of the Forest Plan[2]	Percent of Likely Harvest that is Young Growth
Alternative 1	144,265	40%
Alternative 2	393,937	46%
Alternative 3	513,676	39%
Alternative 4	891,986	26%
Alternative 5	686,583	33%
Alternative 6	663,471	33%
Alternative 7	1,069,624	25%

[1] Based on the ASQ. Incorporates adjustments for falldown.
[2] Includes productive old growth and young-growth harvest.

The number of stream miles within development LUDs can be used as an index to risk for fish resources from harvest-related actions. As shown in Table 3.6-6, the stream habitat at risk closely follows the quantity of harvest. The total stream miles in development LUDs ranges from a low of 4,300 miles for Alternative 1 to 19,900 miles for Alternative 7 (Table 3.6-6). Class I streams are considered most important because these are anadromous and high-quality resident fish streams. Class I stream miles range from about 1,300 miles under Alternative 1 to 5,300 miles under Alternative 7. Total fish stream miles (Class I and II) range from 2,300 under Alternative 1 to 9,500 under Alternative 7. Streams receive substantial protection from riparian buffers and the beach fringe under all of the alternatives. In general, the riparian protections would greatly reduce direct effects to fish resources. However, the greater the miles of streams in development LUDs, the greater the risk to fish resources. The lower reaches of all streams under Alternatives 1, 2, 3, 4, 5, and 6 would be protected within a 1,000-foot beach fringe and Class I, II, and III streams would all receive buffers. Alternative 7 would fully protect a smaller portion of lower stream reaches because of only a 500-foot beach fringe. Alterntive 7 would not require buffers on Class III streams, which may affect downstream fish-bearing streams through a reduction in LWD contributions in certain situations (Paustian et al. 2006).

Table 3.6-6
Mapped Stream Miles[1] within Development LUDs by Alternative

	Alternative						
Stream Class	1	2	3	4	5	6	7
I	1,341	2,364	3,037	4,841	3,752	3,628	5,274
II	951	1,772	2,321	3,912	3,117	2,983	4,216
III	2,004	4,582	6,318	9,657	7,618	7,344	10,425
Total	4,295	8,718	11,676	18,411	14,487	13,954	19,915

[1] Note: Streams have been inventoried more completely in areas that were proposed as Development LUDs compared with areas in Non-development LUDs. Development LUDs include Timber Management, Modified Landscape, Scenic Viewshed, and Experimental Forest.

As noted under the road section, disturbance to hillslope regions with potentially unstable soils could cause slumping and mass wasting. While most of the soil types of highest risk potential would be excluded from the timber base, some areas may still be harvested. Regions greater than 67 percent slope are areas with higher potential for slumping (see the *Roads* discussion in this section). The old-growth acreage of these areas that may be harvested is shown in Table 3.6-7. Because of very limited harvest, Alternative 1 has the least area of potential harvest on steep slopes and Alternative 2 is also relatively low. The larger area of harvest on steep slopes would be under Alternatives 4 and 7, while Alternatives 3, 5, and 6 are intermediate.

Table 3.6-7
Estimated Maximum Acres of Old-Growth Harvest on Potentially Unstable Soils (Slopes > 67%) after Full Implementation of the Forest Plan (approximately 100+ years)[1]

Hill Slope	Alternative 1	2	3	4	5	6	7
Harvest Acres on Slopes > 67%	2,414	8,176	12,391	21,592	17,445	16,626	30,036

[1] Includes adjusted harvest acres estimated in the alternatives allowing for approximation of fall down (the reduction between the planned and the actual harvest area due to discovering additional streams, soils issues, etc, during timber sale layout). See Appendix B for details of estimating methods.

Fish Habitat Enhancement and Log Tranfer Facilities

Fish enhancement projects, such as fish passage, stream and lake stocking, and lake fertilization would not be affected by any of the considered alternatives. Project enhancement funding and selection of projects is primarily independent of amount or location of timber harvest; therefore, all alternatives would have similar effects on enhancement activities.

Effects of LTFs on marine aquatic species are addressed in the *Transportation and Utilities* section of this chapter. Generally, effects would be somewhat proportional to the amount of harvest and include slight coverage of shallow (less than 60 feet deep) regions of nearshore habitat with wood debris (primarily bark), affecting primarily benthic marine organisms in very small areas of tidal and subtidal habitat.

Fish/Riparian Panel Assessment Elements

The panel process is described in the *Introduction* to this chapter. The 1995 Fish/Riparian Assessment panel included four fisheries scientists and two physical scientists (hydrology and geomorphology). The 1997 assessment meeting included just the original four fisheries scientists. The first panel assessed both effects to fish and stream physical attributes (relating to riparian conditions), while the second panel only assessed effects to fish of a subset of the alternatives included in the 1997 EIS.

The detailed results of the first assessment panel analysis is presented in the 1997 FEIS (USDA Forest Service 1997a) and will only be summarized here because many of the factors among current and past alternatives differ. At the time of the first panel meeting, the 1997 Alternative 11 (Alternative 5 [No Action] in this analysis) was not available to the panels. The second panel, however, included this alternative in its assessment. The 2007 alternatives that are based on a corresponding 1997 alternative are as follows:

- 2007 Alternative 4 was based on 1997 Alternative 6
- 2007 Alternative 5 was based on 1997 Alternative 11
- 2007 Alternative 6 was based on 1997 Alternative 11
- 2007 Alternative 7 was based on 1997 Alternative 2

The extension of the panel assessments from the 1997 alternatives to the corresponding 2007 alternatives are primarily based on similarities in acres and locations of potential harvest, miles of proposed roads, and the level of riparian protection and beach/estuary protection between the alternative pairs. In general, the acres and locations of harvest and the miles of proposed roads are very similar for each alternative pair. Similarly, the beach/estuary protection level is the same within each pair. The level of riparian protection is also the same between the 2007 Alternatives 5 and 6 and the 1997 Alternative 11. However, the 2007 Alternative 4 has slightly greater riparian protection than the 1997 Alternative 6, and the 2007 Alternative 7 has the same riparian protection as the 1997 Alternative 2. The extension of panel assessment conclusions is qualified below, where appropriate.

The fisheries and physical scientists rated five possible outcomes for each of eight species of fish, including both resident and anadromous life strategies for two of the species. The fish considered included all five salmon species, cutthroat trout, steelhead, and Dolly Varden char. The physical scientist rated the effects of each alternative on natural stream conditions based on stream attributes, including amount of large woody debris, percent pool area, and stream width-to-depth ratio; residual pool depth; and stream bed grain size for a similar five possible outcomes.

The panels for fish and riparian estimated the effect of each alternative in one of five outcomes (categories) of effects to fish and riparian conditions. Alternatives rated in the first two outcomes (Outcome I and II) generally had mostly no or minimal adverse effects to fish or riparian conditions. Alternatives that had greater portion of ratings in Outcomes III, IV, and V had moderate to severe rated adverse effects to fish or riparian conditions (Dunlap 1996, 1997).

Generally, adverse effects of any alternative in the 1997 EIS were lower and varied less among alternatives on Chinook and sockeye salmon than other species. This is because most Chinook salmon in the Tongass region are present in large river systems (mostly flowing out of Canada) or on Admiralty Island, and most of these systems would have little management activity that could affect them. Sockeye salmon primarily spawn and rear in lakes (although some stream spawning does occur), and lake areas are well protected under all alternatives. Other species, including coho, pink and chum salmon, cutthroat trout, steelhead, and Dolly Varden char are more at risk from management activities because of their greater reliance on stream habitats for spawning, rearing (fry, juvenile), and immigration. The outcome rating for these species was more varied among alternatives and varied among species, mostly based on the amount time and number of life stages spent within streams of the Tongass. Generally, the panel assessments concluded that the level of road construction and timber harvest was positively related to the level of risk to fish and fish habitats. This same trend would hold for the 2007 alternatives.

The scientists in the panels noted several factors they considered important in their evaluation of risks for these alternatives (Dunlap 1996, 1997). These parameters are relevant for evaluation of the current alternatives. Generally, roads were considered the greatest risk to fish resources. Amount, location, and type of timber harvest, especially relative to steep slopes, soil type, stream type, and estuaries were also considered very important in affecting risk. Watershed analysis was important where guidelines would be modified. Also, high levels of riparian protection were a major item considered important for protection of fish resources and their habitat. Firm standards, guidelines, and adequate monitoring were all considered important. Most of the panel's concerns and recommendation were considered and adopted into the final alternative selected for 1997 and are incorporated into Alternatives 1, 2, 3, 5, and 6, to a slightly lesser extent into Alternative 4, and even less into Alternative 7.

The panels described the significant characteristics of each of the alternatives that affected their evaluation. Below is a summary of the 2007 alternatives presented with reference to the panel assessments.

Alternative 1: This alternative would have future harvest and road construction concentrated in a relatively small part of the Forest, which would reduce additional degradation and facilitate recovery of degraded habitat in some watersheds. Riparian and beach/estuary protection would be high because the Alternative's Riparian and Beach/Estuary Standards and Guidelines are essentially the same as the current Forest Plan standards and guidelines. These are the same as the 1997 Alternative 11 standards and guidelines, which were highly rated by the expert panel. Overall, harvest and road construction levels would be the lowest among the alternatives. Because of the low level of harvest and road construction as well as the level of riparian protection, if this alternative were to be evaluated by the panel today, it would likely rank as the lowest risk alternative among the alternatives considered in this EIS, and would generally rank between the two lowest risk alternatives of the 1997 alternatives.

Alternative 2: This alternative is similar to Alternative 1, but with moderately greater distribution of harvest area and increase in roads. Riparian and beach/estuary protection would remain high for the same reasons as for Alternative 1. Harvest and road construction would be increased moderately over Alternative 1 expanding into some new area, but still remain relatively low. It would rank second lowest risk among alternatives evaluated in this EIS and would likely have been between the second and third lowest risk alternative evaluated by the panel in the 1997 EIS.

Alternative 3: This alternative increases harvest considerably over Alternative 1 by expanding into many more watershed areas. However, riparian and beach/estuary protection would remain high for the same reasons as Alternative 1. The moderate network of roads and harvest would increase likelihood of areas of habitat degradation and reduce likelihood of habitat recovery. This alternative, based on riparian protections and moderate harvest, would be ranked third lowest for risk among this EIS alternatives and likely would have been ranked between the third and fourth among alternatives for the 1997 EIS by the panel.

Alternative 4: This alternative is based on the 1997 Alternative 6. The panel assessments concluded that the relatively large area harvested and moderate road network in this alternative would increase the chance of gaps in fish distribution and fish habitat recovery (Dunlap 1996). The old-growth reserves and retention proposed in this alternative may offset some of the harvest and road effects. However, if this alternative were evaluated by the panel today, it would likely rank as the second highest risk alternative among the alternatives considered in this EIS; it ranked in the middle of the 1997 alternatives evaluated (Dunlap 1996).

Alternative 5 (No Action): This alternative is the 1997 Forest Plan (Alternative 11) as amended. The panel assessment concluded that the relatively few miles of roads and moderate levels of timber harvest over the next 100 years in this alternative would reduce risk to fish habitat (Dunlap 1997). Further, the panel noted that the Forest-wide relatively high riparian protections would have relatively low risks to fish habitat (Dunlap 1997). If this alternative were evaluated by the panel today, it would likely rank as the third highest risk alternative among the alternatives considered in this EIS; it ranked in the lower risk group of alternatives in 1997 (Dunlap 1997).

Alternative 6 (Proposed Action): This alternative was based on the 1997 Alternative 11. This alternative would have very slightly lower harvest and roads than the current Alternative 5. The panel assessment concluded that the relatively few miles of roads and moderate levels of timber harvest over the next 100 years in this alternative would have relatively low risk to fish habitat (Dunlap 1997). Further, the panel noted that the Forest-wide relatively high riparian protections would reduce the risks to fish habitat (Dunlap 1997). If this alternative were evaluated by the panel today, it would likely rank as the fourth highest risk alternative among the alternatives considered in this EIS; it would have ranked in the lower risk group of alternatives in 1997 (Dunlap 1997).

Alternative 7: This alternative was based on the 1997 Alternative 2. The panel assessment concluded that the road network and area harvested would increase the likelihood of areas of future habitat degradation and reduce the likelihood of habitat recovery (Dunlap 1996). Of particular concern was harvest on MMI 3 soils, which has greater potential to increase stream habitat degradation and increase risks to stream channels and fish habitat due to lower riparian protection along Class III streams (Dunlap 1996, 1997). In addition, the 1997 panel assessment concluded that management of slopes around steep-gradient Class III streams could change the rate of wood and sediment delivery and affect downstream fish habitat over the long term (Dunlap 1997). This alternative was thought to result in degradation of fish habitat and increase gaps in fish distribution in the next 100 years (Dunlap 1997). Estuary protection would be high because of the essential continuation of current Forest Plan standards and guidelines for estuaries, which were highly rated by the panel (Dunlap 1997). Although beach protections are reduced for this alternative relative to others. Overall, harvest and road development would be the highest, and riparian protections the lowest, of all alternatives. If the panel were to assess this alternative it would likely rate it as the highest risk to fish resources of any in this EIS. The comparable 1997 alternative was rated second highest for risk among all alternatives evaluated in 1997.

Species Assessments

Threatened and Endangered Species

Consultation requirements for the Forest Plan Revision under Section 7 of the ESA, as amended, were completed with the USFWS and NMFS for the 1997 Forest Plan EIS. Both USFWS and NMFS reviewed the biological assessments for threatened and endangered species under their regulatory jurisdiction and concluded that the Tongass Forest Plan Revision was “not likely to adversely effect” threatened or endangered species occurring on the Tongass for the 1997 Plan. These findings were made subject to the programmatic scope of the Forest Plan Revision and following the associated Forest-wide standards and guidelines (see Chapter 4 of the 1997 Forest Plan).

Formal and informal consultation procedures (as directed by the ESA, as amended in 50 CFR 17.7, and Forest Service Manual 2670) are used with NMFS and USFWS on all projects that implement the 1997 Forest Plan. Forest-wide standards and guidelines (see Chapter 4 of the amended Forest Plan) for threatened, endangered, and sensitive species direct that all projects would comply with requirements of the ESA, as amended, and Forest Service policy (Forest Service Manual 2670).

Because Alternative 11 of the 1997 Forest Plan Revision Final EIS was deemed not likely to adversely affect threatened or endangered species occurring on the Tongass, the alternatives being examined in this EIS would also likely fall in this category because they have the same or similar protective measures as Alternative 11 from the 1997 Final EIS, with the exception of greater acreage harvested under Alternatives 4 and 7.

Most of the currently ESA-listed salmon and steelhead are unlikely to be in marine waters near the Tongass Forest because their migration routes and rearing areas mostly to the west of the forest boundaries, although a small number may be present in the inner waters. Because of this very limited distribution relative to the project and lack of affects to the marine environment, it is not anticipated that adverse effects would occur to listed fish species from any of the alternatives. The Biological Assessment for the considered actions is presented in Appendix F. The conclusion of this Biological Assessment is that the considered actions for the Tongass Land and Resource Management Plan are "not likely to adversely effect" any endangered or threatened salmon or steelhead ESU/DPS.

Essential Fish Habitat Assessment

Section 305(b)(2) of the Magnuson-Stevens Act requires all federal agencies to consult with the Secretary on all actions or proposed actions authorized, funded, or undertaken by the agency that may adversely affect EFH. This consultation is done for site-specific projects with ground-disturbing activity. The application of Forest-wide standards and guidelines and BMPs developed to meet soil protection, water quality standards, and fish habitat protection will help protect EFH on the Tongass National Forest and adjacent estuarine and marine waters. Because adoption of the Forest Plan does not specifically result in any actions that could affect EFH, and any action that would be taken following adoption of the Plan that could affect EFH would have a formal EFH developed, no formal EFH was developed for the considered actions in this EIS.

Sensitive Species

Northern Pike

Northern Pike are found in five lakes east of Yakutat. Forest-wide standards and guidelines for wetlands and riparian management generally cover these areas. Although road access exists within 0.5 mile of Pike Lakes, there is no land suitable for timber harvest immediately around the lakes. Natural habitat conditions associated with the lakes are expected to be maintained under all alternatives; therefore, no effects are anticipated.

Fish Creek Chum Salmon

The habitat for the Fish Creek chum salmon, near Hyder on the Portland Canal, would be managed in accordance with the Forest-wide standards and guidelines for wetlands and riparian management (see Chapter 4 of the amended Forest Plan) under all alternatives; one exception is the elimination of Class III stream buffers under Alternative 7. Additional standards and guidelines for chum salmon that apply to the Fish Creek chum salmon include coordination with appropriate agencies to protect, maintain, and preserve this run of chum salmon, and to provide for habitat improvement as necessary to maintain the viability of the run. Alternative 1 is expected to have no effect on the Fish Creek chum salmon. Alternatives 2, 3, 4, 5, and 6 would have a slight risk of effects, but if effects occur, they are not expected to be significant. Alternative 7 would have a larger risk of effects because of the elimination of Class III stream buffers under this alternative; but the potential for significant effects is still small.

There have been improvement projects to increase spawning habitat for this population. With these improvement projects, the habitat for these chum salmon is expected to be improved in the future. Alternatives 2, 3, 4, 5, 6, and 7 would maintain the current LUD as Scenic Viewshed, which would allow continued habitat improvements. Alternative 1 would convert this area to Remote Recreation, which may limit continued enhancement activities and/or the ability to conduct stream habitat improvement projects.

Island Run King Salmon

King Salmon River and Wheeler Creek habitats for island run king salmon are both within Kootznoowoo Wilderness. Natural habitat conditions are to be maintained, and specific Forest-wide standards and guidelines also apply (see Chapter 4 of the amended Forest Plan). None of the alternatives would change how this area would be managed. Application of the wilderness prescription and Forest-wide standards and guidelines to sustain habitat conditions would not result in any affects on these island run king salmon.

Invasive Aquatic Species

ADF&G lists four species of fish that are non-native to Alaska found in Alaskan waters (Fay 2002). Only two, the Eastern Brook trout and Atlantic salmon, have been found in the aquatic habitats of the Tongass National Forest. Additionally, northern pike, which has only been found in apparently native waters in the Yakutat area in the Tongass, is of greatest concern because of its potential to directly impact native salmon species. Other aquatic species, including the Chinese mitten crab and New Zealand mudsnail, both of which can inhabit freshwater, are a major concern for impacts they would cause if they invaded these aquatic habitats (Schrader and Hennon 2005, Fay 2002). While no alternative would have substantial effects on invasion or establishment of non-native aquatic species, some actions could have potential indirect effects. One of the biggest concerns for invasive fish is active stocking of waters primarily with species often considered game fish in other areas. This would apply primarily to northern pike, which can inhabit lakes and rivers. In general then, alternatives that increase human access to fresh waters within the Forest would have the greatest risk of increasing invasive aquatic species in aquatic habitat of the Forest. The major form of increased access to aquatic habitats of the Forest would be through increased roads where people may travel with invasive species either intentionally, such as northern pike, or by accident, such as in the case of some aquatic species, like the New Zealand mudsnail. Based on this criterion, the relative risk would be proportional to road miles (Table 3.6-2) with Alternative 1 having the least and Alternative 7 having the most risk.

Some negative effects, or more appropriately, increased risk to, the natural range of variation in stream processes and fish habitat would likely occur by management activities over the long term for all alternatives. The extent of harvest activity and associated road development are likely to result in decreases of some fish populations in managed watersheds. Measures taken to mitigate, or moderate, the negative effects have been incorporated into the alternatives in ways to reduce levels of risk to the fisheries resource. All alternatives have the same or substantially similar standards and guidelines that influence fish habitat as were adopted following the 1997 EIS. While the standards and guidelines do supply substantial protection of fisheries resources, some risk of impacts would remain, and these are generally proportional primarily to the amount of road miles and to a lesser degree on acres harvested. Therefore, the major difference between the alternative is the relative risk from the construction of roads and harvest, which are directly proportional to the quantity of these two parameters by alternative. In general, Alternatives 1, 2, and 3 would have the lowest risk because of low harvest and road miles, 5 and 6 would be intermediate and similar because harvest is very similar, and Alternative 4 and especially 7 would have most risk to fish resources due to the relatively high portion of harvest and road building.

Conclusions – Direct and Indirect Effects

Much of this EIS evaluation has been based on the conclusions, derived from scientific literature, monitoring reports, and expert evaluations, that current Forest Plan standards and guidelines, practices, and related BMPs are adequate to ensure minimal or no harm to fish resources, at least for most of the alternatives considered. However, there is a degree of scientific uncertainty associated with these conclusions. The current Plan has only been in place for 10 years, although many of the practices have been in place longer. The active monitoring that has been occurring does not suggest marked problems with water quality or fish resources as a result of these actions (USDA Forest Service 2004c, 2006b). While active monitoring has been occurring, the full effect of these types of actions has not had an extensive period of evaluation. Even though relevant information indicates protections would be adequate under most of the alternatives, there is some risk to fisheries resources in implementing any of the considered alternatives.

Based on best available science, it can be concluded that there is a relatively low long-term risk to fish habitat from Alternatives 1, 2, 3, 5, and 6 because of low to moderate levels of timber harvest and road construction, and the relatively high riparian protections offered by Forest Plan standards and guidelines. Under Alternative 4, the risks are higher because of an increase in harvest and road development, and the risks are higher yet under Alternative 7 because of further increases in harvest and road development, and a decrease in riparian protections for Class III streams.

Cumulative Effects

General

The effects of the alternatives on fish resources may be influenced by other actions occurring in the project area. The main cumulative factors affecting fish are related to land development actions that occur regionally. This includes primarily other timber harvest-related actions on non-NFS lands, especially associated roads. The total lands within the Tongass National Forest boundary, which includes all NFS lands and other non-NFS lands, equals about 17.8 million acres. Of this, only about 6 percent (1.1 million acres) are non-NFS lands. However, development actions on these non-NFS lands, which include most cities and towns in Southeast Alaska, are moderately intense.

As discussed previously, one of the main factors affecting fish resources in the Tongass is the level of road development. Generally, the greater the density of roads in the watershed, the greater risk there is to fish resources. Among several indicators used by NMFS (1996) to characterize status of watershed conditions, they recommended a maximum road density threshold levels for maintaining “properly functioning” watersheds for coastal salmon as 2 miles per square mile, with increased risk to salmon as road densities increase beyond this value. There are 947 VCUs inside the Tongass boundary, including both NFS and non-NFS lands. VCUs approximate watershed sizes, so road densities by VCU would be comparable for evaluating conditions relative to NMFS threshold road densities.

The average road densities by alternative and for the region are shown in Table 3.6-8. For this assessment, we have assumed an increase in road miles on non-NFS lands for the life of the project (100+ years). The average road density on non-NFS lands is much higher than on NFS lands. This high average density is partly the result of the high number of road miles in city areas, as well as concentrated timber harvest areas. Even though the amount of non-NFS land area is relatively low, high density on these lands results in the overall average densities increasing sharply relative to NFS lands. However, even with these increases, overall averages remain relatively low for any alternative, ranging from 0.42 (Alternative 1) to 0.60 (Alternative 7).

Table 3.6-8
Estimated Average Total Road Density on Tongass NFS Lands and Non-NFS Lands within the Tongass National Forest Boundary by Alternative over 100+ years[1]

	Road Density as Miles/Square Mile		
Alternative	Road Density on NFS Lands	Road Density on Non-NFS Lands[2]	Total Road Density All Lands
Existing	0.19	2.19	0.31
Alternative 1	0.22	3.49	0.42
Alternative 2	0.29	3.49	0.47
Alternative 3	0.32	3.49	0.49
Alternative 4	0.40	3.49	0.57
Alternative 5	0.35	3.49	0.53
Alternative 6	0.35	3.49	0.52
Alternative 7	0.43	3.49	0.60

[1] Assumes full implementation of Forest Plan at ASQ levels plus future non-NFS harvest. Includes adjusted roads miles estimated to be needed to harvest all suitable timber in the alternative allowing for approximation of fall down (the reduction between the planned and the actual roads needed due to discovering additional streams, soils issues, etc, during timber sale layout). Annette Island is included because it is surrounded by areas within the Forest boundary.
[2] Assumes an estimated the increase in non-NFS road miles within the Forest boundary from 3,756 miles at present to 5,970 after 100+ years.

However, there are VCUs that have higher road densities that are increased by the addition of roads from the alternatives (Table 3.6-9). Currently, most (68 percent) of the VCUs on NFS lands have no roads and only just over 2 percent have road densities exceeding 2 miles per square mile. The inclusion of non-NFS lands reduces the percentage of VCUs with no roads to 61 percent and pushes the portion of VCUs exceeding 2 miles per square mile to almost 6 percent under existing conditions. Under Alternatives 1 and 2 for all lands combined, the percentage of VCUs exceeding 2 miles per square mile would increase to a maximum of 10 to 12 percent after 100+ years. The largest increase in the percentage of VCUs with high density would occur under Alternative 7, which would have a maximum of 16 percent of VCUs exceeding the 2 miles per square mile threshold.

After 100+ years, Alternatives 3 through 6 would have a maximum of 12 to 14 percent of VCUs with density greater than 2 miles per square mile when roads on non-NFS lands are included. When roads on all lands are included, a minimum of about 37 to 46 percent of the VCUs would still have no roads after 100+ years (Table 3.6-9).

The effect on fish resources are less directly tied to amount of harvest than to roads, but harvest may influence them through effects on water quality, riparian management, and regions where harvest is allowed, as discussed under direct effects. The cumulative effects of timber harvest were discussed in the *Water* section on water quality for all lands (including non-NFS lands) within the Forest boundary and relate to potential effect to fish resources. Existing conditions include retention of 87 percent of the original productive old-growth forest inside the Forest boundary and with 95 percent of the land area remaining undisturbed from direct timber harvest (Table 3.4-3 of the *Water* section). Overall the cumulative effects to fish relating directly to quantity of timber harvest would be least for Alternative 1 as 82 percent of the original productive old growth on all lands within the Forest boundary would be retained and greatest for Alternative 7 as productive old growth would be reduced to 70 percent, in addition to reduced riparian protections for Alternative 7. Even with highest harvest alternative, the majority of productive old

[1] Assumes full implementation of Forest Plan at ASQ levels plus future non-NFS harvest. Roads on NFS lands adjusted for fall down. Estimated the increase in non-NFS road miles within the Forest boundary from 3,756 miles at present to 5,970 after 100+ years. Annette Island is included as a VCU because it is surrounded by areas within the Forest boundary.
[2] For NFS lands, percentages are based on 935 VCUs that contain at least 100 acres of NFS lands. For all lands, percentages are based on all 947 VCUs inside the Forest boundary, including Annette Island.

growth would remain unaffected for the full implementations of the Forest Plan over more than a 100-year period (Table 3.4-3 of the *Water* section). Total cumulative effects to fish resources, based on relative amount of area disturbed, would be relatively low as 90 to 94 percent of the land base would remain undisturbed by direct timber harvest for all alternatives. However, some local regions may have fish resources affected where watershed harvest levels and road density are high. Additionally, with less protections for riparian areas on state and private land (e.g., no required buffers on non-fish bearing streams, and some fish bearing streams), a greater risk to fish resources would occur in watersheds that have a high portion of non-NFS harvest occurring. Again, effects of harvest activities on fish resources would ultimately be considered at the project-specific levels, ensuring minimal adverse cumulative effects.

Climate Change

Climate change is one factor that has some unquantifiable potential to affect fishery resources on the Tongass. While the models do not fully agree on the climate change predictions for Southeast Alaska, they generally predict warmer weather, with more winter rainfall, less snowfall, and a decrease in summer rain in some areas. Both factors, if large enough, have the potential to affect fish resources. Climate models from both the Canadian Climate Center and the Hadley Center predict rising temperatures and a 10 percent decrease in summer precipitation in portions of Southeast Alaska (though they differ on the areas affected). Given the high summer rainfall levels in Southeast Alaska (Ketchikan averages over 7 inches of rain per month in the summer), a 10 percent decrease in summer rainfall would still result in wet conditions in most years. However, Southeast Alaska does occasionally experience dryer conditions. For example, in July 1971 there were 23 days without rain. Juday et al. (1998) postulate that warmer, dryer conditions could increase stream temperatures and cause reduced seasonal low flows, both of which could adversely affect salmon. Reduced stream flow in summer months and high water temperatures during this same period have been a common concern for salmonid populations in much of their native range. These types of concerns are less prominent in the cool wet environment common in Southeast Alaska, although some conditions of low flow and higher stream temperature resulting in adverse effects have been observed. Specific concerns, for example, include changes in the timing of emerging pink and chum salmon and the potential for not being properly timed with early marine planktons supplies (Heard and Salo 1991), and elevated temperatures and lower summer flows reducing holding pool survival of adults because of dissolved oxygen depletion.

In the case of coho salmon, sidechannels may have lower flows and increased temperatures, which could reduce their usability. However, increased temperature could reduce rearing time in freshwater for coho salmon from 2 years to 1, which may have advantages (less overwinter mortality) and disadvantages (smaller size on marine water entry, reducing marine survival). Sea-level rise could inundate estuarine rearing areas. However, the Southeast Alaska land mass is rising in many areas, and the potential change in water level over the next century is 0.3 to 3 feet, while some areas, particularly in northern Southeast Alaska, may rise several feet 1 to 4 feet (Kelly et al 2007). Changes in the next decade or two, will obviously be much less. So overall effects on estuarine areas and fish stocks will vary considerably and, within the timeframe covered by this Forest Plan amendment (i.e., 10 to 15 years) changes are difficult to predict and may even be difficult to detect.

In summary, there is general agreement that the climate is warming and that summer precipitation is may decline. However, there is considerable uncertainty surrounding specific predictions and even more uncertainty regarding the effect of these changes on resources including fish.

Conclusions – Cumulative Effects

Overall, the cumulative effects of considered alternative actions in conjunction with other non-NFS lands and actions associated with timber harvest would increase the regions of greatest risk for fish resources. While all alternatives would increase high road density areas, overall the number of VCUs of increased risks to fish remains relatively small, at 16 percent for the entire region, even for Alternative 7, which has the highest average density and the highest frequency of high road density areas. Other alternatives would have less risk with high road density areas ranging from about 10 to 14 percent for all lands combined. Cumulative effects of actual timber harvest would follow a similar trend among the alternatives; however, the potential cumulative effects of harvest, road building, and other actions would be evaluated on a project-specific basis so that the potential for adverse cumulative effects to fish resources within a given watershed could be reduced or eliminated.

Plants

Affected Environment

This section describes the affected environment for plants on the Tongass National Forest. It is divided into three areas of focus: Plant Communities, Threatened, Endangered, and Sensitive (TES) Species, and Invasive Plants. The *Plant Communities* subsection below provides an overview of vegetation and describes the process and status of vegetation classification and vegetation mapping on the Tongass. The *Threatened, Endangered, Sensitive, and Rare Plant* and *Invasive Plant Species* subsections below include an overview of current conditions.

Plant Communities

The composition, age, and structure of the plant communities present today on the Tongass are the result of interactions between biological and physical environments, natural disturbances, and land use history. This subsection introduces the ecological context for the occurrence of common forested and non-forested plant communities.

The coastal forest of Southeast Alaska is part of the cool, temperate rain forest that extends along the Pacific coast from Northern California to Cook Inlet in Alaska. Most of the Forest is composed of old-growth conifers, primarily western hemlock *(Tsuga heterophylla)* and Sitka spruce *(Picea sitchensis)*, with a scattering of mountain hemlock *(Tsuga mertensiana)*, Alaska yellow-cedar *(Chamaecyparis nootkatensis)*, and western redcedar *(Thuja plicata)* in the south. Red alder *(Alnus rubra)* is common along streams, beach fringes, and on soils recently disturbed by management activities and landslides. Black cottonwood *(Populus balsamifera* ssp. *trichocarpa)* grows on the floodplains of major rivers and recently deglaciated areas.

Blueberry and huckleberry *(Vaccinium* spp.), Sitka alder *(Alnus viridis* spp. *sinuata)*, devil's club *(Oplopanax horridus)*, and salal *(Gaultheria shallon)* are common shrubs in forested communities. The Forest floor is habitat for a variety plants, such as false lily-of-the-valley *(Maianthemum dilitatum)*, bunchberry *(Cornus canadensis)*, five-leaf bramble *(Rubus pedatus)*, and skunk cabbage *(Lysichiton americanum)*. Because of the high rainfall and resulting high humidity, a large variety of mosses grow in great profusion on the ground, fallen logs, the lower trunks and branches of trees, as well as in forest openings. Hundreds of epiphytic lichen species can also be found on tree trunks and branches, especially in old-growth forests, riparian areas, and maritime beach fringe forests.

Grass and sedge meadows usually lie at low elevations, often along the coast and toeslopes of hills and mountains. Stands of willows *(Salix* spp.) border many of the stream channels. Muskeg (peatland) communities, dominated by shore pine *(Pinus contorta* var. *contorta),* peat moss *(Spaghnum* spp.), and sedges *(Carex* spp.), occur throughout the Forest. These non-forest vegetation types are also described in the *Wetlands* and *Biodiversity* sections of this chapter.

Alpine and sub-alpine vegetation usually occurs above 2,500 feet elevation. The sub-alpine zone is often dominated by mountain hemlock (*Tsuga mertensiana*) where the coastal forest treeline begins to decline into low-lying and krumholtz vegetation between 2,500 and 2,800 feet elevation. Resident plants have adapted to persistent snow cover and wind desiccation by evolving low-growth forms. Mat-forming heaths, such as mountain heather (*Cassiope* spp. and *Phyllodoce* spp.), cover much of the area, with cushion-like flowering plants and non-vascular plants (lichens, mosses, and liverworts) occupying exposed rock outcrops, crevices, and talus slopes.

The detailed description and effects analysis to vegetation on a habitat/landscape scale can be found in the *Biodiversity* section of this chapter.

Vegetation Classification

Integrating vegetation information in analysis, planning, and decisionmaking includes the development of vegetation classifications, the use of the classifications to map vegetation with remotely sensed imagery, and ecological models. Classification of vegetation types is an effective tool for studying, understanding, and communicating habitat information. Vegetation classifications at appropriate scales have been widely used in wildlife management, forest planning, project planning, and silviculture in the National Forests. Vegetation classifications can be used to identify realistic objectives and management opportunities, determine capability and suitability, and evaluate forest health. They can be used to streamline monitoring design and facilitate extrapolation of monitoring interpretations; assess risks for the introduction of invasive species, fire, insects, and disease; and describe current habitats for plant and animal species based on current vegetation composition, structure, and function. Function refers to the interactions and influences between plant and animal species within an area and their environment, including natural processes of change or disturbance (wind, aging, etc.).

On the Tongass National Forest, fine-scale vegetation communities known as plant associations have historically been used for project-level planning and analysis of silvicultural treatments. Work on describing forested plant communities on the Tongass began in the early 1980s. Three guides, one each for the former Ketchikan, Stikine, and the Chatham Areas, were developed to identify and describe forested plant associations (DeMeo et al. 1992, Pawuk and Kissinger 1989, Martin et al. 1995). They provide a key for identifying the plant associations based on dominant and diagnostic species in the tree, shrub, and herb layers of the Forest. Plant association names consist of the dominant tree species that occurs in the overstory canopy, along with dominant or diagnostic species found in the shrub and/or herb strata (layers). Plant association descriptions include species cover and constancy (how often a species occurs in a particular association), productivity estimates, and management considerations to guide the interpretation of effects of actions on an area with a specific plant association.

In the Tongass plant association guides, forested plant associations are grouped into the following series based on the dominant tree species in the overstory canopy:

- Mixed-Conifer Series
- Mountain Hemlock Series
- Shore Pine (Lodgepole Pine) Series
- Sitka Spruce Series

- Western Hemlock Series
- Western Hemlock-Western Red Cedar Series
- Western Hemlock-Yellow Cedar Series

The Federal Geographic Data Committee established the National Vegetation Classification Standards (NVCS), which is a hierarchical existing vegetation classification with nine levels (Federal Geographic Data Committee 1997). The seven upper levels are primarily based on physiognomy. The two lowest levels, alliance and association, are based on floristic attributes. This hierarchy has been incorporated into the recently published Forest Service Existing Vegetation Classification and Mapping Technical Guide (Brohman and Bryant 2005). All of the forested plant associations of Southeast Alaska have been crosswalked to the NVCS. A list of the crosswalked forested plant associations can be found on the Alaska Natural Heritage Program (ANHP) Web site at: http://aknhp.uaa.alaska.edu/ecology/Ecology_Plant_Association_Tracking_List.htm.

Development of a non-forested vegetation classification for the Tongass is currently in progress. The Yakutat Forelands plant community classification (Shephard 1995) included a classification of non-forested vegetation types. In order to produce a consistent product for the rest of the Tongass that is compatible with the NVCS and meets the needs of the Forest Service, the protocols in the Forest Service Existing Vegetation Classification and Mapping Technical Guide are being followed. Once the non-forested classification is complete, a guide containing descriptions of plant associations will be developed.

Vegetation Mapping

The only Forest-wide vegetation map currently available is the Tongass Existing Veg map, a GIS-based data set that was derived from the former TimberType database. In Existing Veg, forested stands are identified by broad forest canopy cover types. Information for forested stands includes dominant overstory species, type for low productivity stands, size class (e.g., seedling, sapling, young growth, or old growth), and volume class for productive stands. Generic non-forested types are also mapped (e.g., ice, shrub, muskeg, beach, alpine, and sand).

A new, interim model for classifying productive forests of the Tongass has been developed that organizes forested stands in the Existing Veg map into seven size-density categories (Caouette and DeGayner 2005). This system, referred to as the Size-Density Model (SD7), is described in the *Biodiversity* section of this chapter, and may be useful for describing forest structural diversity and wildlife habitats.

Mapping vegetation communities at the plant-association level has not occurred on the Forest. Producing plant-association maps requires large amounts of field data and high-resolution imagery combined with modeling; therefore, plant-association maps will most likely need to be developed on a project-specific basis, while still meeting Forest-wide standards for vegetation mapping. New and updated mid-level (alliance and/or dominance type) maps of vegetation types sufficient for Forest- or watershed-scale analysis may be developed in the near future.

Threatened, Endangered, Sensitive, and Rare Plants

There are no federally listed or proposed Threatened or Endangered plants that are known to occur or are likely to occur on the Tongass National Forest. The only federally listed or proposed plant in Alaska is the Aleutian hollyfern (*Polystichum aleuticum)*, which is listed as endangered; however, it is only known to occur on Adak Island and is not expected to occur on the Tongass National Forest.

Sensitive plant species are those plant species identified by the Regional Forester for which population viability is a concern on National Forest System (NFS) lands within the region. A viability concern is identified by either a significant current or predicted downward trend in population numbers or density, or a significant current or predicted downward trend in habitat capability that would reduce a species' existing distribution. The goal of the Forest Service Sensitive Species Program (Forest Service Manual 2670) is to ensure that species numbers and population distribution are adequate so that no federal listing will be required and no extirpation will occur on NFS lands.

ANHP's Rare Species Global Rankings Criteria is the primary source of information used to rank rare plant species in Alaska. The Regional Sensitive Plant Species List identifies certain rare plants on the ANHP list as sensitive and are known or suspected to occur on the Tongass. There are currently 17 plant species listed as sensitive on the Tongass National Forest. Revisions to the Regional Sensitive Plant Species list are periodically recommended based on new information derived from recent publications, field work, and laboratory analysis concerning rare plants.

The sensitive plants known or suspected to occur in the Tongass National Forest are listed in Table 3.7-1. This table includes a general range and habitat description for each species. In addition, it includes a preliminary estimate of the potential number of acres of habitat for each species. These estimates are likely to be overestimates of available habitat, because the habitat requirements of sensitive plant species are often not well known and, even when they are well known, the habitat requirements are generally tied to micro-habitat characteristics. These estimates are based on available Tongass Forest GIS mapping and, as a result, are tied to macro-habitat information that is currently available. Nevertheless, they provide a means or an index of measuring the effects of the alternatives by assessing the percentage of each habitat affected.

Sensitive plant surveys are conducted as part of project planning to identify populations or habitats of sensitive species within planning areas. An understanding of the distributions of sensitive and rare plants on the Tongass is limited because most botanical surveys are focused on project areas. As a result, very few Forest-wide inventories have been conducted.

ANHP maintains a list of plants that are considered rare within Alaska. This list currently contains 86 plants (including those with sensitive or rare designations, or with significant range extensions on the Tongass) documented to occur on the Tongass National Forest. Rare plant species are those that are inherently rare or not naturally well distributed on the Forest; however, rare plants do not have the same protection in the Forest-wide standards and guidelines or the same determination language as sensitive plants. The State of Alaska list of rare plants, with global and state rankings, is used as guidance for determining which rare plants may be addressed in the project-level analysis. The State list with state and global rankings is available online at: http://aknhp.uaa.alaska.edu/botany/Botany_tracking_page.htm. Generally, plants with a state ranking of S1 (critically imperiled in state) or S2 (imperiled in state) are given consideration during project analysis.

Table 3.7-1
Regional Forester Sensitive Plant Species that are Known or Suspected to Occur on the Tongass National Forest[1]

Common Name (*Scientific Name*)	Range and Habitat[2]
Eschscholtz's little nightmare (*Aphragmus eschscholtzianus*)	This plant is confined to southern Alaska and adjacent areas in Canada in a band extending from the Aleutians through the southwest Yukon. The plant is known from about 30 sites throughout its range. It is suspected to occur in mountainous areas on the northern mainland of the Tongass. It grows in moist mossy areas, seeps, heaths, and scree slopes in the subalpine and alpine. Because the plant is so small, it is easily overlooked. This plant has not been documented on the Tongass. The Tongass contains a high estimate[2] of approximately 1,424,000 acres of habitat that is potentially suitable for Eschscholtz's little nightmare.
Norberg arnica (*Arnica lessingii* ssp. *Norbergii*)	This plant has been found in less than 20 sites in a range extending from Prince William Sound through the northern panhandle. The plant grows from sea level to subalpine in meadows, shrublands, dry meadows, and open forest. This plant has been identified in five locations on the Yakutat Ranger District. The Tongass contains a high estimate[2] of approximately 502,000 acres of habitat that is potentially suitable for Norberg arnica.
Moonwort fern, no common name (*Botrychium tunux*)	This fern has a specific habitat found on well-drained open areas on maritime beaches or upper beach meadows. Six populations have been found on the Yakutat Ranger District. The Tongass contains a high estimate[2] of approximately 16,000 acres of habitat that is potentially suitable for *Botrychium tunux.*
Moonwort fern, no common name (*Botrychium yaaxudakeit*)	This plant is found on well-drained open areas on maritime beaches or upper beach meadows. Five populations are known on the Yakutat Ranger District. The Tongass contains a high estimate[2] of approximately 16,000 acres of habitat that is potentially suitable for *Botrychium yaaxudakeit.*
Goose-grass sedge (*Carex lenticularis* var. *dolia*)	The sedge ranges from the Aleutians east to the Alaska-Canada Coast Range, through the Rockies south to Glacier National Park. It grows in wet meadows, along lakeshores and snowbeds, generally at high elevations. There are seven known locations on the Juneau, Ketchikan, and Sitka Ranger Districts. Recent research has recognized *Carex enanderi* as the same species as *Carex lenticularis* var. *dolia*. Consequently, goose-grass sedge is more common than thought, although still rare. It is proposed to remove this plant from the sensitive species list. The Tongass contains a high estimate[2] of approximately 526,000 acres of habitat that is potentially suitable for goose-grass sedge.
Edible thistle (*Cirsium edule*)	This plant ranges from southern Southeast Alaska, through western Washington, to extreme northwestern Oregon. It grows in open meadows, scree slopes, and along glacial streams and lakeshores. There are three documented locations in the Misty Fiords National Monument. This plant is expected to occur elsewhere in the southeast portion of the Tongass National Forest. The Tongass contains a high estimate[2] of approximately 695,000 acres of habitat that is potentially suitable for edible thistle.
Davy mannagrass (*Glyceria leptostachya*)	This plant has a range from central Southeast Alaska, disjunctly south through central California. It grows in shallow freshwater and along stream and lake margins. In Alaska, it has been identified at five sites in Ketchikan, Wrangell, and Sitka areas. The Tongass contains a high estimate[2] of approximately 1,314,000 acres of habitat that is potentially suitable for Davy mannagrass.
Wright filmy fern (*Hymenophyllum wrightii*)	This fern's range is disjunct from Russian Far East, Korea, and Japan to the Petersburg and Sitka areas in the Tongass National Forest, south to about four sites in British Columbia coastal areas and the Queen Charlotte Islands. Only the gametophyte stage has been recorded in Alaska, while the sporophyte stage has been documented on the Queen Charlotte Islands. It grows on shaded cliff faces; bases of trees; decaying wood and rootwads; and in the dense, humid coastal forests near saltwater and low elevation areas. It has been found on Biorka, Baranof, Chichagof, Mitkof, Etolin, and Kupreanof Islands The Tongass contains a high estimate[2] of approximately 8,845,000 acres of habitat that is potentially suitable for Wright filmy fern.
Truncate quillwort (*Isoetes truncata*)	This plant grows immersed in shallow fresh water pools or ponds. It is known from Kodiak and Vancouver Islands, with a disjunct population at Pyramid Lake, Alberta. It is suspected to occur from Prince William Sound through the Tongass National Forest. There are three documented locations on the Sitka Ranger District. The plant on the Tongass is thought to be a hybrid of more common species: *Isoetes occidentalis, I. maritima* and possibly *I. echinospora.* Therefore, it is proposed that this plant be removed from the sensitive species list. The Tongass contains a high estimate[2] of approximately 31,000 acres of habitat potentially suitable for wright filmy fern within the Tongass.

Table 3.7-1 (continued)
Regional Forester Sensitive Plant Species that are Known or Suspected to Occur on the Tongass National Forest[1]

Common Name (*Scientific Name*)	Range and Habitat[2]
Calder lovage (*Ligusticum calderi*)	This plant is known from Vancouver Island north through the southern part of the Tongass National Forest (Dall and Prince of Wales Islands) and disjunct to Kodiak Island. It occurs in alpine and subalpine meadows, boggy slopes, and rocky areas. It has been identified in 10 locations in the Craig Ranger District. The Tongass contains a high estimate[2] of approximately 681,000 acres of habitat that is potentially suitable for Calder lovage.
Pale poppy (*Papaver alboroseum*)	A rather spectacular poppy, this species has been identified in three disjunct areas: Kamchatka and northern Kurile Islands; Cook Inlet, Kenai Peninsula, Portage Glacier; and northern British Columbia and southern Yukon. The plant grows in open areas, recently deglaciated areas, rock outcrops, sand, gravel, and on well-drained soils. In the Tongass National Forest, it is suspected on the mainland in the Skagway and Juneau areas. It has been identified in seven locations on the Sitka Ranger District. The Tongass contains a high estimate[2] of approximately 1,598,000 acres of habitat that is potentially suitable for the pale poppy.
Bog orchid (*Platanthera gracilis*)	This orchid is known from a limited range in the southernmost part of the Tongass and adjacent British Columbia. It has been identified at four sites in wet meadows and is expected in peat bogs. Little is known about this plant. Distributions, population size, population trends, existence of historical populations, and habitat requirements have not yet been determined. This plant has been synonimized with the common *Platanthera stricta* and is proposed to be removed from the sensitive list. The Tongass contains a high estimate[2] of approximately 84,000 acres of habitat that is potentially suitable for the bog orchid.
Loose-flowered bluegrass (*Poa laxiflora*)	This grass ranges from the Hoonah area south to Oregon. The plant grows in upper beach meadows, open areas, open forests, and along riparian areas. It is suspected to occur throughout the Tongass National Forest from the Juneau Ranger District south. There are over 20 populations on the Juneau, Craig, Petersburg, and Ketchikan Districts, and Admiralty Island National Monument. The Tongass contains a high estimate[2] of approximately 7,287,000 acres of habitat that is potentially suitable for loose-flowered bluegrass.
Kamchatka alkali grass (*Puccinellia kamtschatica*)	This grass ranges from the Aleutians through the central Tongass National Forest. It grows on tidal flats, salt marshes, and sea beaches. The status of this species is in question. Some authors recognize it as a distinct species; others do not. Current research on *Puccinellia* may conclude that this species is the same as the much more common *Puccinellia nutkaensis*. The Tongass contains a high estimate[2] of approximately 26,000 acres of habitat that is potentially suitable for Kamchatka alkali grass.
Unalaska mist-maid (*Romanzoffia unalaschcensis*)	This plant ranges from the Aleutian Islands through Prince William Sound, disjunct to the Tongass National Forest. The plant grows in cracks in rock outcrops; along stream banks; beach terraces; open rocky areas; and on grassy, mossy rock cliffs along shores. There are two documented occurrences on Thorne Bay and Sitka Ranger Districts. At a very broad scale, the Tongass contains a high estimate[2] of approximately 3,158,000 acres of habitat that is potentially suitable for Unalaska mist-maid.
Queen Charlotte butterweed (*Senecio moresbiensis*)	This plant has been found in the southern half of the Tongass National Forest, Queen Charlotte Islands, and northern Vancouver Island. It grows in alpine and subalpine meadows, boggy or rocky slopes, open rocky heaths, or grassy areas. It has been found adjacent to a road on Prince of Wales Island. Less than 15 populations have been documented on the Thorne Bay and Craig Ranger Districts. The Tongass contains a high estimate[2] of approximately 681,000 acres of habitat that is potentially suitable for Queen Charlotte butterweed.
Circumpolar starwort (*Stellaria ruscifolia ssp. aleutica*)	This plant ranges from the eastern Aleutians east across southern coastal Alaska to the northern Tongass. This plant is inconspicuous and difficult to identify. It grows in open gravely sites and along creeks in the mountains. It has been identified in one location on the Yakutat Ranger District. The Tongass contains a high estimate[2] of approximately 176,000 acres of habitat that is potentially suitable for circumpolar starwort.

[1] Sensitive Plant list updated June 2002.
[2] Habitat acreage estimates for each species are approximate and tend to overestimate the potential habitat because they are based on macro-habitat information currently available in GIS. Nevertheless, they provide a means of measuring the effects of the alternatives by assessing the percentage of each habitat affected.

Invasive Plant Species

In the past, Alaska's remoteness and relatively low disturbance level has protected it from infestations of non-native plants. Compared to the lower 48 states, Alaska has a low level of invasive plants, but it is growing. As inventories have increased, more non-native species have been documented in Southeast Alaska on NFS lands (Schrader and Hennon 2005). Not all non-natives are invasive. Executive Order 13112 (1999) defines an "invasive species" as a species that is 1) non-native (or alien) to the habitat under consideration, and 2) whose purposeful or accidental introduction causes or is likely to cause economic or environmental harm or harm to human health. Executive Order 13112 directs all federal agencies to address invasive species concerns and refrain from actions likely to increase invasive species problems.

Many existing laws and directives provide management direction for "noxious" plants. Noxious is a political designation used by state or federal governments and, in the past, has primarily been driven by threats to agriculture or rangelands. Laws pertaining to only "listed noxious species" are inadequate in addressing threats to NFS lands in Alaska. The Forest Service recognizes this and refers to species of concern as "invasive." Invasive species terminology, in this document, includes noxious and invasive alien plant species.

There are two programs in Alaska that were created to track occurrences of non-native plants and rank the invasiveness of non-native species. The first program is Alaska Exotic Plants Information Clearinghouse (AKEPIC), a database administered and coordinated by ANHP. AKEPIC is a cooperative project between the USDA Forest Service, State and Private Forestry, the National Park Service, U.S. Geological Survey, University of Alaska, and other federal, state, and local agencies in support of the Alaska Committee for Noxious and Invasive Plants Management and the Strategic Plan for Noxious and Invasive Plants Management in Alaska. The Tongass National Forest maintains an inventory of occurrences of non-native plants in the AKEPIC database to track and monitor occurrences. The database is available online at: http://akweeds.uaa.alaska.edu/.

The second statewide program is the Weed Ranking Project that was created to better assess what species could be most problematic in the Alaska system. The Weed Ranking Project assesses the potential invasiveness of non-natives that have been found in Alaska and non-natives that have been invasive in other locations and for which there is appropriate habitat in Alaska. The invasiveness rankings are available online through ANHP at: http://akweeds.uaa.alaska.edu/akweeds_ranking_page.htm.

During the past several years, surveys along some roads, trails, trailheads, and other sites of recent human activity in Southeast Alaska have been conducted. Recently, systematic surveys of all non-native species have been initiated in areas of heavier use that are more susceptible to non-native plant invasion. The areas of greatest non-native plant diversity and extent of invasion have been found around towns and the most heavily traveled areas. The areas with the lowest number of species were further from population centers or paved roads (Arhangelsky 2005). Schrader and Hennon (2005) cited references that suggest that highest invasive plant occurrences are in areas of human activity, such as roads, recreational areas, industrial, commercial, and industrial development.

Survey results of all non-natives found on the Tongass are documented in the AKEPIC inventory. The data do not provide the extent of infestation, but do include the location of species found. While the database includes some entries for the Tongass starting in 2000, the majority of the entries are from 2002 and later. Table 3.7-2 shows the number of non-native species found on the Tongass during

Table 3.7-2
Number of Non-Native Species Recorded by District

Ranger District	Number of Non-Native Species Recorded[1]
Admiralty National Monument	17
Craig Ranger District	56
Hoonah Ranger District	10
Juneau Ranger District	17
Ketchikan-Misty Fiords Ranger District	26
Petersburg Ranger District	21
Sitka Ranger District	24
Thorne Bay Ranger District	59
Wrangell Ranger District	28
Yakutat Ranger District	14
Total	**88**

[1] Sites may be very close to each other and done on the same day (e.g., the survey of Prince of Wales Is included recording non-native species every 0.25 mile of road)
Source: AKEPIC 2006 and Tongass GIS

surveys. The number of species is notably larger on the Craig and Thorne Bay Ranger Districts due to the systematic survey of roads completed on Prince of Wales Island in 2005.

The 2005 systematic survey of Prince of Wales Island also provided information that many more species exist than had previously been recorded on the island. The 2005 survey of Prince of Wales Island recorded 33 new species of non-native plants on NFS lands (Arhangelsky 2005).

Table 3.7-3 shows a list of all non-native plant species recorded on the Tongass National Forest and invasiveness rankings from the Alaska Weed Ranking Program. The rankings are for the South Coastal zone of Alaska and range from 1 to 100 (100 representing the highest invasiveness rating) for the species that have an invasiveness ranking.

Of the 88 species of non-natives on the Tongass, 46 have an invasiveness ranking. The invasiveness ranking is based on analysis of four parameters for each species, including:

- Ecological impact: impact on processes, community structure and composition, and other trophic levels.
- Biological characteristics: mode of reproduction, methods of dispersal, competitive abilities, and habitat.
- Ecological amplitude and distribution: United States and global distribution, and level of impact in other locations.
- Feasibility of control: seed bank viability, other methods of reproduction, and effort known to be required for control.

Table 3.7-3
Non-Native Plants on the Tongass: Number of Occurrences and Invasiveness Ranking

Common Name	Scientific Name	No. of Locations on the Tongass[1]	Invasiveness Ranking [2]
alfalfa	*Medicago sativa*	2	
alsike clover	*Trifolium hybridum*	417	57
annual bluegrass	*Poa annua*	460	51
annual hawksbeard	*Crepis tectorum*	25	43
bird's foot trefoil	*Lotus corniculatus*	6	
bitter dock	*Rumex obtusifolius*	2	
black bindweed, wild buckwheat	*Polygonum convolvulus*	7	51
black medic, hop clover	*Medicago lupulina*	57	48
bladder campion	*Silene latifolia*	1	45
bluegrass	*Poa pratensis*	654	57
brittlestem hempnettle	*Galeopsis tetrahit*	67	
bull thistle	*Cirsium vulgare*	92	61
burr medic	*Medicago minima*	4	
butter and eggs	*Linaria vulgaris*	21	
Canada bluegrass	*Poa compressa*	83	35
Canada thistle	*Cirsium arvense*	72	76
Canary grass	*Phalaris canariensis*	1	
cat's-ears	*Hypochoeris radicata*	161	
chicory	*Cichorium intybus*	1	
colonial bentgrass	*Agrostis tenuis.*	56	
common chickweed	*Stellaria media.*	22	57
common comfrey	*Symphytum officinale*	6	
common dandelion	*Taraxacum officinale*	1,681	62
common dogmustard	*Erucastrum gallicum*	6	
common groundsel	*Senecio vulgaris*	31	
common hawkweed	*Hieracium lachenalii*	12	
common plantain	*Plantago major* var. *major*	2,264	44
common St. Johnswort	*Hypericum perforatum*	15	52
common tansy	*Tanacetum vulgare*	39	57
common velvetgrass	*Holcus lanatus*	238	
common yarrow	*Achillea millefolium*	120	48
creeping bentgrass, red top	*Agrostis gigantea*	463	
	Agrostis stolonifera	126	
creeping buttercup	*Ranunculus repens*	526	54
crested wheatgrass	*Agropyron cristatum*	1	
curled dock	*Rumex crispus*	24	48
European mountain ash	*Sorbus aucuparia*	1	
fall dandelion	*Leontodon autumnalis*	2	
field bindweed	*Convolvulus arvensis*	2	
field mustard	*Brassica rapa*	66	
fowl bluegrass	*Poa palustris*	830	
foxtail barley	*Hordeum jubatum*	8	63
garden dock	*Rumex longifolius*	4	
garlic mustard	*Alliaria petiolata*	12	70
golden clover	*Trifolium aureum*	1	
hedge false bindweed	*Calystegia sepium* ssp. *sepium*	1	
Himalayan blackberry	*Rubus armeniacus (R. discolor)*	1	
Italian rye grass	*Lolium multiflorum*	5	41
Japanese knotweed	*Polygonum cuspidatum*	254	87
lamb's quarters	*Chenopodium album*	7	
large-leaf lupine	*Lupinus polyphyllus*	77	
larger mouse-eared chickweed	*Cerastium fontanum Baumg*. ssp. *triviale*	1,262	39
maltesecross	*Lychnis chalcedonica*	2	
marsh cudweed	*Gnaphalium palustre*	11	
mayweed, stinking chamomile	*Anthemis cotula*	3	41

Table 3.7-3 (continued)
Non-Native Plants on the Tongass: Number of Occurrences and Invasiveness Ranking

Common Name	Scientific Name	No. of Locations on the Tongass[1]	Invasiveness Ranking [2]
meadow foxtail	*Alopecurus pratensis*	15	
meadow hawkweed	*Hieracium caespitosum*	8	
mouseear hawkweed	*Hieracium pilosella*	1	
Narrow-leaf Hawkweed	*Hieracium umbellatum*	60	35
night-flowering catchfly	*Melandrium noctiflorum*	1	
Norwegian cinquefoil	*Potentilla norvegica*	2	
orange hawkweed	*Hieracium aurantiacum*	325	71
orchard grass	*Dactylis glomerata*	610	
ornamental jewelweed	*Impatiens glandulifera*	2	
ox-eye daisy	*Leucanthemum vulgare*	610	
perennial rye grass	*Lolium perenne*	162	
perennial sowthistle	*Sonchus arvensis*	8	59
pineappleweed	*Matricaria discoidea*	140	34
prickly lettuce	*Lactuca serriola*	8	
purple foxglove, foxglove	*Digitalis purpurea*	73	51
purple-topped turnip	*Brassica rapa* var. *rapa*	6	
quackgrass	*Elymus repens*	5	
Queen Anne's lace	*Daucus carota*	1	
red clover	*Trifolium pratense*	206	
reed canary grass	*Phalaris arundinacea*	3,120	83
ribgrass, buckhorn, English plantain	*Plantago lanceolata*	2	
rough bluegrass	*Poa trivialis*	34	
rough hawkbit	*Leontodon hirtus*	3	
scentless mayweed	*Tripleurospermum inodorum*	1	48
scotch broom	*Cytisis scoparius*	22	69
sheep sorel	*Rumex acetosella* ssp. *acetosella*	86	45
	Rumex acetosella ssp. *angiocarpus*	2	
shepherd's purse	*Capsella bursa-pastoris*	6	40
	Capsella rubella	1	
silverweed	*Potentilla anserina*	3	
slender hairgrass	*Deschampsia elongata*	304	
smooth brome	*Bromus inermis*	9	62
sneezeweed	*Achillea ptarmica*	1	46
spearmint	*Mentha spicata*	1	
spiny sowthistle	*Sonchus asper*	35	
splitlip hempnettle	*Galeopsis bifida.*	5	43
spotted knapweed	*Centaurea biebersteinii*	6	88
spurry	*Spergula arvensis*	1	
stick chickweed	*Cerastium glomeratum*	1	
tall buttercup	*Ranunculus acris*	1	
tall fescue	*Festuca arundinacea*	20	
tansy ragwort, stinky willie	*Senecio jacobea*	9	63

Environmental Consequences

Direct and Indirect Effects

This section compares effects of the seven alternatives on sensitive and rare plant species and on the introduction or spread of invasive species. There would be no effects to Threatened or Endangered plant species because there are none found on the Tongass.

Threatened, Endangered, Sensitive, and Rare Plants

Direct effects of the proposed alternatives on sensitive or rare plants would include physical damage to sensitive plants by cutting, trampling, or crushing them with vehicles, other machinery, foot traffic, or felled trees. Severe impacts may cause mortality, or inhibit the vigor and reproductive capability of the plants.

Indirect effects involve alteration of habitat, such as changes in sunlight and moisture availability, herbivore or pollinator behavior, soil structure and fertility, vegetation structure, and competition from other native species as well as invasive and other non-native species. Some indirect effects, such as changes in sunlight or moisture, can be beneficial or harmful depending on the effect and the specie's life history. For example, if a plant has habitat requirements of partial sun, then increasing the size of a forest opening may benefit that species; however, that same opening may be harmful to a plant that requires shade. Activities likely to cause indirect effects to sensitive and rare plants include removal or reduction of tree canopy, road construction, changes in hydrology associated with road construction, increased competition by invasive plants, construction of other facilities, increased off-road vehicle use, increased access, and increased use and associated trampling by recreationists.

The alternatives described in Chapter 2 differ primarily by the proposed amount of timber that is likely to be harvested and the miles of road construction and reconstruction. Alternative 5, the No-Action Alternative, would follow the 1997 Forest Plan standards and guidelines. The other six alternatives would mostly follow the proposed standards and guidelines, which provide additional protection for sensitive and rare plants. There are three exceptions that could affect sensitive and rare plants: the area of non-development LUDs, beach buffer requirements, and Class III stream protection. Table 2-16 in Chapter 2 provides a comparison of the components of the alternatives.

Alternatives 1, 2, 3, and 6 would have more acreage in old-growth reserves and other non-development LUDs than Alternative 5 (current Forest Plan) or Alternatives 4 and 7. This increased area in reserves would provide more area in large blocks of intact habitats, which would be beneficial to sensitive and rare plants. Alternative 4 utilizes a reduced old-growth strategy and Alternative 7 would reduce non-development LUDs even further (including the elimination of the Old-Growth Habitat LUD). This could contribute to the risk of direct or indirect effects to sensitive or rare plant species that generally occur in old-growth habitats. Both Alternatives 4 and 7 could result in the loss of local viability for some sensitive species due to the creation of large gaps within old-growth habitat. Species listed as sensitive on the Tongass that include forest or forest openings as a potential habitat are Norberg arnica, Wright filmy fern, and loose-flowered bluegrass.

In Alternative 7, the beach buffer would be reduced to 500 feet for timber harvest, compared to 1,000 feet in the other alternatives. This would increase the risk of direct or indirect effects to species that inhabit areas close to shore or in low elevations. The species listed as sensitive on the Tongass that may inhabit areas close to shore are moonwort fern, Wright filmy fern, loose-flowered bluegrass, Kamchatka alkali grass, Unalaska mist-maid, Queen Charlotte butterweed, and circumpolar starwort.

Finally, Alternative 7 is different from the other alternatives in that it would not require timber harvest buffers along Class III streams. As a result, plant species that occupy riparian areas along steep, rocky and mountainous streams would not receive the same degree of protection under Alternative 7.

Construction of roads would involve removal of vegetation within the path of the road. This could affect rare and sensitive plants that inhabit the specific habitat found within the location of the new road. Roads can be constructed in many types of habitat, depending on the need for access for forestry activities.

Reconstruction of a road for timber harvest maintains the original investment and makes the road suitable and safe for the intended use. Reconstruction for forestry activities involves the rehabilitation of the original roadbed. It can include cleaning ditches, replacing drainage structures, re-installing bridges, and grading and shaping. The roadbed had been created and used (compacted) in the past and, in general, no longer supports sensitive or rare plants; however, newly exposed bedrock in unique geological areas can create new habitat for rare and sensitive plants. Road maintenance can include reconditioning the original road template, grading the road surface, cleaning roadside ditches, and removing vegetation that may encroach upon the road or block vision. Because the maintenance activities remain in the road prism, this would be unlikely to have an effect on sensitive or rare plants.

In general, alternatives with low amounts of timber harvest and road construction would have less risk of direct and indirect effects. Alternatives with more acres proposed for harvest and road construction would have more risk of effects. Other activities related to timber harvest, such as log transfer facility (LTF) construction, would increase with elevated timber harvests. Effects to sensitive and rare plants would, therefore, also be related to the amount of timber harvest allowed.

Alternative 5, the No-Action Alternative, proposes harvesting up to approximately 463,000 acres of old growth and constructing up to 3,874 miles of new roads over the next 100+ years (Table 3.7-4). Alternatives 1 and 2 would maintain the most acres of undisturbed forest and have less risk of adverse effects due to harvest and related activities. Alternatives 1 and 2 propose harvesting approximately 86,000 and 215,000 old-growth acres, respectively, or 19 to 46 percent of the acreage proposed in Alternative 5 (No Action). Alternatives 1 and 2 also propose constructing approximately 20 and 54 percent of the road miles proposed by Alternative 5. Alternatives 3 and 6 are in the middle of the alternatives in terms of acres for harvest and road construction. They include harvesting 335,000 and 445,000 acres, respectively, or 72 and 96 percent of the maximum acres of old growth proposed under Alternative 5. They propose to construct up to 2,799 and 3,744 miles of new road, respectively. Alternatives 4 and 7 propose the highest level of harvest and road construction and would have the highest risk of adverse effects due to harvest and related activities. They would harvest a maximum of 656,000 to 807,000 acres of old growth, respectively, and would build more miles of roads to achieve that harvest than any other alternative. Following Table 3.7-4 is a discussion of the likely effects to sensitive and rare plants, taking into account the Forest management direction for activities proposed by the alternatives.

Table 3.7-4
Maximum Acres of Harvest and Maximum Miles of Road Construction by Alternative

	Alternative						
	1	**2**	**3**	**4**	**5**	**6**	**7**
Maximum Acres Likely to be Harvested after Full Implementation of the Forest Plan (thousands of acres after 100+ years)							
Productive Old Growth	86.0	214.5	313.4	656.5	462.6	445.1	807.4
Young Growth	58.3	179.4	200.2	235.5	224.0	218.4	262.2
Total Acres	**144.3**	**393.9**	**513.7**	**892.0**	**686.6**	**663.5**	**1,069.6**
Maximum Miles of Road Likely to be Constructed							
New Road Construction	774	2,079	2,799	4,890	3,874	3,744	5,825
Road Reconstruction	925	1,784	1,932	2,182	2,100	2,046	2,371
Total Road Work (includes reconstruction)	**1,948**	**4,344**	**5,252**	**7,660**	**6,541**	**6,342**	**8,836**

Sensitive Plants

Within all alternatives, a biological evaluation, including a sensitive plant review, is prepared for individual project proposals as part of the site-specific environmental analysis. The sensitive plant review is required to include sufficient detail to determine how a proposed action may affect each sensitive species. The intensity and scope of inventories selected to provide information for effects analysis is required to be commensurate with the potential risk of a proposed project to sensitive plant species. The review is used to evaluate project-level impacts to sensitive plants in order to ensure that proposed project activities do not contribute to population or habitat declines that could lead to federal listing or loss of viability. In addition, appropriate Forest-wide standards and guidelines (TES species) will be applied to sustain those plants and their habitat that are listed as sensitive.

The proposed standards and guidelines for Alternatives 1, 2, 3, 4, 6, and 7 include an additional provision for reviewing the implementation and effectiveness of conservation actions for sensitive plants. This review would provide information to improve conservation efforts and reduce the likelihood of negative effects due to management actions.

The risk of adverse effects to sensitive plants would increase with increasing land disturbance; therefore, over time, Alternatives 4 and 7 would have a higher risk of direct and indirect effects due to harvest and road work, when compared to other alternatives. Alternatives 5 and 6 would have the next highest risk. The acres of harvest and miles of road construction for Alternative 3 is intermediate and its risk to affect sensitive plants would likely fall in the mid-range when compared to the other alternatives. Alternatives 1 and 2 would have the least risk of effects. It should be noted that through project-level evaluation and application of Forest-wide standard and guideline protection measures, it is unlikely the alternatives under consideration would have substantial adverse effects.

A species distribution is limited to areas that can meet the species-specific physical and biological needs. Due to the limited scope of surveys conducted within the Tongass, exact species distributions are unknown; however, by utilizing existing GIS data and available habitat information, areas that contain the necessary biological and physical requirements of each species on a macro-scale can be approximated. Although this analysis can not predict the exact distribution of each species, it can aid in assessing the location and total acreage of potentially suitable habitat for each sensitive species. For the sake of this discussion, potentially suitable habitat is defined as an area where the biological and physical requirements of a sensitive species are met, at least on a macro-scale, based on available GIS data. Although this technique overestimates the actual available habitat, it is likely that it also overestimates the acreage affected and, therefore, it is useful to be able to compare the percent of habitat affected by each alternative. Only 3 of the 17 sensitive species found on the Tongass would experience an impact on more than 0.1 percent of their potentially suitable habitat due to road construction and harvest activities. These include Norberg arnica, Wright filmy fern, and loose-flowered bluegrass. In general, the magnitude of effects for these species declines in order from Alternative 7 to 4, 5, 6, 3, 2, and 1. The effects on each of the sensitive species and their potentially suitable habitat are addressed below and in Table 3.7-5.

Eschscholtz's little nightmare (*Aphragmus eschscholtzianus*):
There is a high estimate of approximately 1,424,000 acres of potentially suitable habitat for Eschscholtz's little nightmare within the Tongass. This species grows within moist mossy areas, seeps, heaths, and scree slopes in subalpine and alpine areas, where harvest would not occur. Very little access to timber through alpine or subalpine areas would be needed. Each of the alternatives considered would impact less than 0.1 percent of potentially suitable habitat (Table 3.7-5). Because of the protection from the Forest-wide standards and guidelines, and the very low chance of impacting this habitat, there is essentially no risk that any alternative would result in loss of this specie's viability, or create significant trends towards federal listing.

Norberg arnica (*Arnica lessingii ssp. Norbergii*):
There is a high estimate of approximately 502,000 acres of potentially suitable habitat for Norberg arnica within the Tongass. This plant grows in various habitats, including open forests where it could be affected by silvicultural practices or associated road construction. The largest effect would result from Alternatives 4 and 7, which could impact approximately 0.3 percent of potentially suitable habitat for Norberg arnica (Table 3.7-5). The magnitude of effect declines in order from Alternative 7 to 4, 5, 6, 3, 2, and 1. Alternative 1 would result in an impact to less than 0.1 percent of potentially suitable habitat. Through project-level evaluation and application of Forest-wide standard and guideline protection measures, and based on the low proportion of habitat potentially affected, there would be a very low risk that effects would result in loss of this specie's viability, or create significant trends towards federal listing.

Moonwort fern, no common name (*Botrychium tunux* and *Botrychium yaaxudakeit*):
There is a high estimate of approximately 16,000 acres of potentially suitable habitat for *Botrychium tunux* and *Botrychium yaaxudakeit* within the Tongass. These plants grow in open areas on maritime beaches or upper beach meadows where harvesting activities would not occur. While access to timber through beaches may be needed if new LTFs are required, it would be infrequent. Each of the Alternatives considered would impact less than 0.1 percent of potentially suitable habitat (Table 3.7-5). Because of the protection from the Forest-wide standards and guidelines, and the very low chance of impacting this habitat, there is essentially no risk that any alternative would result in loss of this specie's viability, or create significant trends towards federal listing.

Goose-grass sedge (*Carex lenticularis* var. *dolia*):
There is a high estimate of approximately 526,000 acres of potentially suitable habitat for goose-grass sedge within the Tongass. This plant grows in moist mossy areas, seeps, heaths, and scree slopes in the subalpine and alpine where harvest would not occur. While access to timber through alpine or subalpine areas may be

needed, it is not likely. Each of the alternatives considered would impact less than 0.1 percent of potentially suitable habitat (Table 3.7-5). Additionally, goose grass sedge is more common than originally thought, although still rare. It has been proposed to be removed from the sensitive species list. With the very low chance of impacting potential habitat and the protection of Forest-wide standards and guidelines, there would be essentially no risk that effects would result in loss of this specie's viability or create significant trends towards federal listing.

Edible thistle (*Cirsium edule*):
There is a high estimate of approximately 695,000 acres of potentially suitable habitat for edible thistle within the Tongass. The likelihood of adverse effects is low because this plant grows in open meadows, scree slopes, and along glacial streams and lakeshores where harvest would not occur; however, access to timber through this type of habitat may be needed. Each of the alternatives considered would impact less than 0.1 percent of potentially suitable habitat (Table 3.7-5). Because of the protection from the Forest-wide standards and guidelines, and the very low chance of impacting this habitat, there is essentially no risk that any alternative would result in loss of this specie's viability, or create significant trends towards federal listing.

Davy mannagrass (*Glyceria leptostachya*):
There is a high estimate of approximately 1,314,000 acres of potentially suitable habitat for davy mannagrass within the Tongass. This plant grows in shallow freshwater and along stream and lake margins where harvest would not occur. While these areas are generally protected by Riparian Standards and Guidelines, it is possible that access to timber through this type of habitat may be needed. Under Alternative 7, road construction would impact approximately 0.1 percent of potentially suitable habitat for davy mannagrass. Road construction and harvest activities under all other alternatives considered would impact less than 0.1 percent of potentially suitable habitat (Table 3.7-5). The magnitude of effect declines in order from Alternative 7 to 4, 5, 6, 3, 2, and 1. With the protection of Forest-wide standards and guidelines along with the Riparian Standards and Guidelines, there is a very low risk that effects would result in loss of this specie's viability, or create significant trends towards federal listing.

Wright filmy fern (*Hymenophyllum wrightii*):
There is a high estimate of approximately 8,845,000 acres of potentially suitable habitat for wright filmy fern within the Tongass. This plant grows in various habitats, including near the bases of trees, on decaying wood and rootwads, and in the dense, humid coastal forests near saltwater and low elevation areas. These areas could be affected by silviculture or associated road construction, indicating that all alternatives considered may affect this sensitive plant. Alternative 7 would impact up to approximately 9 percent of potentially suitable habitat; 0.2 percent of this would be as a result of road construction (Table 3.7-5). The magnitude of effect declines in order from Alternative 7 to 4, 5, 6, 3, 2, and 1. Alternative 1 would impact up to approximately 1 percent of potentially suitable habitat. Through project-level evaluation and application of Forest-wide standard and guideline protection measures, there is a low risk that effects would result in loss of this specie's viability, or create significant trends towards federal listing.

Truncate quillwort (*Isoetes x truncata*):
There is a high estimate of approximately 31,000 acres of potentially suitable habitat for truncate quillwort within the Tongass. This plant grows immersed in shallow fresh water pools or ponds where harvest would not occur. While these areas are protected by riparian standards and guidelines, it is possible that access to timber through this type of habitat may be needed. Each of the alternatives considered would impact less than 0.1 percent of potentially suitable habitat (Table 3.7-5). This

species is more common than previously thought and it has been proposed to be removed from the sensitive species list. With the extremely low chance of impacting this habitat and the protection of Forest-wide standards and guidelines, there is essentially no low risk that effects would result in loss of specie's viability, or create significant trends towards federal listing.

Calder lovage (*Ligusticum calderi*):
There is a high estimate of approximately 681,000 acres of potentially suitable habitat for calder lovage within the Tongass. This plant occurs in alpine and subalpine meadows, boggy slopes, and rocky areas where harvest would not occur. While access to timber through alpine and subalpine areas may be needed, it is not likely. Each of the alternatives considered would impact less than 0.1 percent of potentially suitable habitat (Table 3.7-5). Because of the protection from the Forest-wide standards and guidelines, and the very low chance of impacting this habitat, there is essentially no risk that any alternative would result in loss of this specie's viability, or create significant trends towards federal listing.

Pale poppy (*Papaver alboroseum*):
There is a high estimate of approximately 1,598,000 acres of potentially suitable habitat for pale poppy within the Tongass. This plant occurs in open areas, recently deglaciated areas, rock outcrops, sand, gravel, and on well-drained soils where harvest would not occur. While access to timber through this type of habitat may be needed, it is not likely. Each of the alternatives considered would impact less than 0.1 percent of potentially suitable habitat (Table 3.7-5). Because of the protection from the Forest-wide standards and guidelines, and the very low chance of impacting this habitat, there is essentially no risk that any alternative would result in loss of this specie's viability, or create significant trends towards federal listing.

Bog orchid (*Platanthera gracilis*):
There is a high estimate of approximately 84,000 acres of potentially suitable habitat for bog orchid within the Tongass. This plant grows in wet meadows and peat bogs where harvest would not occur. While standards and guidelines provide protection to wetlands, it is possible that access to timber through this type of habitat may be needed. Each of the alternatives considered would impact less than 0.1 percent of potentially suitable habitat (Table 3.7-5). In addition, this plant has been synonymized with the common *Platanthera stricta* and is proposed to be removed from the sensitive list. With the extremely low chance of impacting this habitat and the protection of Forest-wide standards and guidelines, there is essentially no risk that effects would result in loss of this specie's viability, or create significant trends towards federal listing.

Loose-flowered bluegrass (Poa laxiflora):
There is a high estimate of approximately 7,287,000 acres of potentially suitable habitat for loose-flowered bluegrass within the Tongass. This plant grows in various habitats including along riparian areas and in open forests where it could be affected by silvicutlure or associated road construction. Alternative 7 would impact up to approximately 6 percent of potentially suitable habitat; 0.2 percent of this would be as a result of road construction (Table 3.7-5). The magnitude of effect declines in order from Alternative 7 to 4, 5, 6, 3, 2, and 1. Alternative 1 would impact 0.6 percent of potentially suitable habitat. Through project-level evaluation and application of Forest-wide standard and guideline protection measures, there is a low risk that effects would result in loss of this specie's viability, or create significant trends towards federal listing.

Kamchatka alkali grass (*Puccinellia kamtschatica*):
There is a high estimate of approximately 26,000 acres of potentially suitable habitat for Kamchatka alkali grass within the Tongass. This plant occurs in tidal flats, salt

marshes, and sea beaches where harvest would not occur. While access to timber through beach areas may be needed if new LTFs are required, it would be infrequent. Each of the alternatives considered would impact less than 0.1 percent of potentially suitable habitat (Table 3.7-5). Because of the protection from the Forest-wide standards and guidelines, and the very low chance of impacting this habitat, there is essentially no risk that any alternative would result in loss of this specie's viability, or create significant trends towards federal listing.

Unalaska mist-maid (*Romanzoffia unalaschcensis*):
There is a high estimate of approximately 3,158,000 acres of potentially suitable habitat for Unalaska mist-maid within the Tongass. The plant grows in cracks within rock outcrops, along stream banks, beach terraces, open rocky areas, and on grassy/mossy rock cliffs along shores where harvest would not occur; however, access to timber through these habitats may be needed. Each of the alternatives considered would impact less than 0.1 percent of potentially suitable habitat (Table 3.7-5). Because of the protection from the Forest-wide standards and guidelines, and the very low chance of impacting this habitat, there is essentially no risk that any alternative would result in loss of this specie's viability, or create significant trends towards federal listing.

Queen Charlotte butterweed (*Senecio moresbiensis*):
There is a high estimate of approximately 681,000 acres of potentially suitable habitat for Queen Charlotte butterweed within the Tongass. This plant grows in meadows, boggy or rocky slopes, open rocky heaths, or grassy areas where harvest would not occur. While access to timber through these areas may be needed, it is not likely. Each of the alternatives considered would impact less than 0.1 percent of potentially suitable habitat (Table 3.7-5). With the very low chance of impacting this habitat and the protection of Forest-wide standards and guidelines, there is essentially no risk that effects would result in loss of this specie's viability, or create significant trends towards federal listing.

Circumpolar starwort (*Stellaria ruscifolia* ssp. *aleutica*):
There is a high estimate of approximately 176,000 acres of potentially suitable habitat for circumpolar starwort within the Tongass. This plant grows in open gravely sites and along creeks in the mountains where harvest would not occur; however, access to timber through this type of habitat may be needed. Each of the alternatives considered would impact less than 0.1 percent of potentially suitable habitat (Table 3.7-5). Because of the protection from the Forest-wide standards and guidelines, and the very low chance of impacting this habitat, there is essentially no risk that any alternative would result in loss of this specie's viability, or create significant trends towards federal listing.

Rare Plants

The proposed standards and guidelines for all alternatives, except Alternative 5 (No Action), include additional protection for rare plants. Alternatives 1, 2, 3, 4, 6, and 7 include the proposed standards and guidelines that provide specific direction to avoid, minimize, or mitigate adverse effects to rare plants and populations during project planning. The additional protection provided by the proposed standards and guidelines would reduce the risk of adverse effects on rare plants.

Table 3.7-5.
Maximum Effects on Potential Suitable Habitat for Sensitive Plant Species by Alternative (contributing effect of roads shown in parentheses)

Common Name (*Scientific Name*)	Total Potential Suitable Habitat (acres)	Percent of Total Potential Suitable Habitat Affected by Alternative						
		1	2	3	4	5	6	7
Eschscholtz's little nightmare (*Aphragmus eschscholtzianus*)	1,424,000	< 0.1%	< 0.1%	< 0.1%	< 0.1%	< 0.1%	< 0.1%	< 0.1%

Source: Tongass National Forest GIS database
Percent of total potential suitable habitat affected is calculated by estimating potential suitable macro-habitat using available GIS descriptors of habitat and then intersecting these habitat areas with areas to be affected by the alternatives.
Values in parentheses *( )* represent the contributing effect of roads to the total percent of habitat affected.

Alternative 5 is covered by the 1997 Forest Plan standards and guidelines, which did not include specific protection for rare plants; however, protection of rare plant populations and their habitats in a proposed project area is generally accomplished through project analysis and planning. Effects of a proposed action on rare plant species and their habitats are generally addressed in plant resource reports.

The effects of the alternatives on rare plants would be more heavily influenced by the area of timber harvest and road construction. Therefore, the likelihood of adverse effects to rare plants would be highest for Alternative 7, followed by Alternatives 4, 5, 6, 3, 2, and 1.

Invasive Plant Species

Invasive plants can adversely affect an area either when invasive plants become established or when an existing species spreads to occupy a larger area. Invasive plants can negatively affect habitat by competing for resources such as water and light, establishing and changing the community composition, eliminating or reducing native plants, or by changing the vegetation structure. The changes in community composition or vegetation structure can reduce native plant populations as well as negatively affect habitat for wildlife. Highly invasive plant species often have aggressive reproductive methods and can successfully compete for resources (Schrader and Hennon 2005).

Ground disturbance associated with management activities on the Forest can provide an opportunity for invasive plant introduction or expansion. This would be a direct effect of timber harvest or road construction because the activities disturb soil and/or remove existing vegetation, providing openings for invasive plants to establish or spread. Movement of equipment can also provide opportunities for seed transport into new areas. Indirect effects can include the establishment or spread of invasive plants through the use of roads after harvest for recreation or during road maintenance. In general, land disturbance effects to invasive plants can be wider than the effects in the specific area of disturbance due to the interconnectedness of land.

The Tongass National Forest Invasive Plant Management Plan (Lerum and Krosse 2005) provides guidance for prevention, early detection, control, management, and rehabilitation or restoration of areas with established invasive plants. It incorporates policy and emphasis direction from federal and regional documents, including the Alaska Region Invasive Plant Strategy (USDA Forest Service 2005a).

The proposed standards and guidelines address invasive plants for all alternatives except Alternative 5 (No Action). The proposed standards and guidelines for invasive plants are new and include direction to review proposed projects to determine the risk of introduction or spread of invasive plants and implement appropriate mitigation measures. They also include direction to control existing invasions and rehabilitate habitats impacted by invasive species. The proposed standards and guidelines for Alternatives 1, 2, 3, 4, 6, and 7 would reduce the likelihood of negative effects that would result from the introduction or spread of invasive plant species.

Alternative 5 (No Action) includes the use of the 1997 Forest Plan that does not include specific standards and guidelines for controlling invasive plants. However, when followed, the guidance in the Tongass National Forest Invasive Plant Management Plan (Lerum and Krosse 2005) would provide some protection from invasive plants.

All of the alternatives include timber harvest and new road construction that could directly and indirectly increase invasive plants. Increased disturbance increases the risk of establishment or spread of invasive plants. The effects would vary between alternatives depending on the level of disturbance due to timber harvest and new roads construction.

The acres of harvest and miles of road included in each alternative are shown in Table 3.7-4. Over time, Alternatives 4 and 7 and, to a lesser extent, Alternatives 5 and 6 would have a higher risk of direct and indirect effects due to harvest and road work. In addition, Alternative 5 does not include the revised standards and guidelines; therefore, there is a greater risk of adverse effects for each acre disturbed. The acres of harvest and miles of road construction for Alternative 3 is intermediate; its risk would likely fall in the mid-range when compared to the other alternatives. Alternatives 1 and 2 propose the least amount of disturbance from timber harvest, and roads would have the lowest risk of adverse effects.

Cumulative Effects

Threatened, Endangered, Sensitive, and Rare Plants

When considering effects to sensitive and rare plants, it is important to look at land both inside and outside NFS lands and the cumulative effects of past, present, and reasonably foreseeable future activities. Each landscape area has different physical, chemical, and biological characteristics, as well as different vegetation patterns. The significance of an addition to cumulative effects from management activities would depend on factors such as the amount and type of disturbance in an analysis area, type of vegetation in the area, habitat availability for each sensitive or rare species, known locations of each species, and amount of disturbance in the potential habitat area for each species. Assessing cumulative effects to sensitive and rare plant species will be done for individual projects as part of the National Environmental Policy Act (NEPA) process for the relevant analysis area; however, past plus expected harvest and road construction for forestry and other uses on all land ownerships can be used to compare the risk that each alternative would add to cumulative effects on sensitive and rare plants.

As discussed above, Table 3.7-5 summarizes the amount of each sensitive species potentially suitable habitat on NFS lands affected for each alternative. These values create a baseline set of conditions as well as a prediction of future conditions during the life of the Forest Plan under all alternatives. These data can be used when future project-specific analyses are conducted as part of the NEPA process.

Timber harvesting on state, municipal, and private land is governed by the Alaska Forest Resources and Practices Act (AS 41.17). Alaska Forest Resources and Practices Regulations (ADNR 2004) do not address threatened, endangered, or rare plants; however, they do limit disturbance in marshes and non-forested muskegs, which would provide some protection for those plant species.

To compare the potential cumulative effects of harvest under the seven alternatives on sensitive or rare plants, harvest on lands of all ownerships in Southeast Alaska was analyzed. There are approximately 21.6 million acres of land in Southeast Alaska. Non-NFS lands comprise about 4.8 million acres or 22 percent of the 21.6 million acres in Southeast Alaska; Glacier Bay National Park consists of about 2.5 million acres. Approximately 30 percent of the lands in Southeast Alaska were originally productive old growth (POG). Approximately 13 percent of the POG on all ownerships had been harvested by 2006. Thus, approximately 87 percent of the original POG on all ownerships was remaining in 2006. The percent of POG remaining on NFS lands is higher than for non-NFS lands that lie within the Tongass National Forest boundary (92 and 70 percent, respectively) due to the concentrated timber harvest areas in the non-NFS lands that are within the Tongass boundaries.

Looking at all ownerships of land in the Forest, the POG forest remaining in 100 years under full implementation of the Forest Plan would be greatest for Alternative 1, followed by Alternatives 2, 3, 6, 5, 4, and 7 (Table 3.7-6). Therefore, the risk of cumulative effects to sensitive or rare plants due to harvest would be lowest for Alternative 1, followed by 2, 3, 5, 6, 4, and 7. Table 3.9-17 in the *Biodiversity* section shows a similar relative risk among the alternatives for cumulative effects by Biogeographic Province.

Table 3.7-6
Cumulative Percent of the Original (1954) POG Remaining on All Ownerships in 2006 and after 100+ Years under Full Implementation of the Forest Plan for Each Alternative with Estimated Future Harvest on State, Private, and Other Lands

Remaining POG on All Ownerships in 2006 as a Percent of all Original POG	Remaining POG after 100+ Years as a Percent of 1954 POG						
	Alternative						
	1	2	3	4	5	6	7
87%	82%	80%	78%	73%	76%	76%	71%

Existing road density is greater on the non-NFS lands within the Tongass National Forest boundaries than on the NFS lands due to concentrated harvest and more populated areas. It averages 0.19 mile per square mile on NFS lands and 2.19 miles per square mile for the non-NFS lands. The average for lands of all ownerships is 0.31 mile per square mile; however, those are averages over a very large area and there is great variability. The range of road density by VCU shows large variabilityacross the Tongass as seen in Table 3.6-9 in the *Fish* section (percentage of VCUs by road density category for the Tongass and lands of all ownerships). All VCUs have road densities of less than 4 miles per square mile under existing condition.

Table 3.7-7 shows the average future road density for each alternative. It includes existing roads and forestry as well as other roads proposed for construction on NFS lands and reasonably foreseeable on non-NFS lands. Alternatives 7 and 4, and to a lesser extent Alternatives 5 and 6, would have the highest average road density. Therefore, in those alternatives, there is higher risk that management actions would add to cumulative effects to sensitive or rare plants. The average road density for Alternative 3 is intermediate and its risk of cumulative effects would fall in the mid-range when compared to the other alternatives. Alternatives 1 and 2 would have the least risk of cumulative effects. Table 3.6-9 in the *Fish* section shows a similar relative risk among the alternatives of cumulative effects by VCU.

Table 3.7-7
Future Average Road Density by Alternative (miles per square mile)

	Existing	Alternative						
		1	2	3	4	5	6	7
National Forest Service Land	0.19	0.22	0.27	0.30	0.38	0.34	0.33	0.41
All Ownerships	0.31	0.42	0.47	0.49	0.57	0.53	0.52	0.60

Source: Tongass National Forest GIS database

There are other activities that have occurred in the past and are reasonably foreseeable to occur in the future that have the potential to add to cumulative effects to rare and sensitive plants in regional and local areas. They include mineral extraction, transmission line projects, hydroelectric projects, transportation developments, expansion of cities, and recreational site development. Existing mining is at Greens Creek on Admiralty Island, Berner's Bay north of Juneau, and other locations. Given the level of world pricing, an increase in exploration is expected. There are also several regional transportation projects and regional energy and transmission projects planned for construction. Each of these activities can include clearing vegetation and disturbing habitat for construction and maintenance; therefore, they have the potential to affect sensitive and rare plants and their habitat and would be considered in project analysis.

Changes in Alaska's climate (discussed in the *Climate and Air* section of this chapter) could affect the hydrology and other habitat conditions where the sensitive and rare plants occur. While the models do not fully agree on the climate change predictions for Southeast Alaska, they generally agree on warmer weather with more winter rainfall and less snowfall and a decrease in summer rain in some areas. That would likely result in lower soil moisture due to increased evaporation during warmer, drier summer months. Also, a precipitation shift from snow to rain could lead to more water running off the landscape rather than being stored to feed streams and wetlands in the late spring and summer; thus, increasing evaporation and reducing water storage. These factors could lead to drier streams, meadows, and wetlands.

Changes in temperature and hydrologic conditions would likely favor some plant species and stress others. There has been little research into the effects of changes in environmental conditions for each of the sensitive and rare species; consequently, there is uncertainty as to the effect of changes in the climate on these plant species known or suspected to occur on the Tongass.

Invasive Plant Species

When considering effects to invasive plants, it is important to look at both NFS and non-NFS lands and the cumulative effects of past, present, and reasonably foreseeable future activities. Invasive plants on any land ownership in Southeast Alaska can affect invasive establishment or spread on NFS lands and vice versa. Also, activities on land of any ownership can establish or spread plants that affect other lands. As mentioned in the direct and indirect effects, activities can have wider affects on invasive plants than the specific area of land disturbance due to the interconnectedness of land.

As discussed for rare plants, each landscape area has different characteristics and vegetation patterns. The significance of an addition to cumulative effects of forestry activities would depend on factors such as the amount and type of disturbance in the analysis area, the existence of invasive plants at the time of project implementation, type of vegetation in the area, amount of harvest and road building for a specific project, and the project plans to contain invasive plants. Assessing cumulative effects needs to be done for individual projects in the context of the effects in the relevant analysis area.

Past, present, and future harvest and road construction for harvest and other purposes on lands of all ownerships can be used to compare the risk of Alternative 6 (Proposed Alternative), to cumulative effects due to invasive plant introduction or spread. Table 3.7-7 shows the average existing road density and future road density for each alternative for all land ownerships and for NFS lands. Alternatives 7 and 4 and, to a lesser extent, Alternatives 5 and 6 would have the highest average road density and, therefore, a higher risk of adding to cumulative effects of invasive plants. The average road density for Alternative 3 is intermediate; its risk of cumulative effects would fall in the mid-range when compared to the other alternatives. Alternatives 1 and 2 would have the least risk of cumulative effects due to an individual project.

As discussed under cumulative effects for sensitive and rare plants, there are fewer restrictions on timber activities on non-NFS lands than on NFS lands. Timber activities on non-NFS lands that can contribute to the introduction or spread of invasive plants are not specifically regulated by the State of Alaska. To compare the risk of effects of harvest in the seven alternatives on invasive plants, POG remaining on land of all ownerships was analyzed. Looking at all ownerships of land in the Forest, the POG (unharvested) forest remaining in 100 years under full implementation of the Forest Plan would be greatest for Alternative 1, followed by Alternatives 2, 3, 6, 5, 4, and 7 (Table 3.7-6). Therefore, the risk of cumulative effects to be substantial for invasive plants due to harvest would be highest for Alternative 7, followed by 4, 5, 6, 3, 2, and 1.

There are other activities that have occurred and are reasonably foreseeable to occur in the future that have the potential to add to cumulative effects of invasive plants. They include mineral extraction, transmission line projects, hydroelectric projects, transportation developments, expansion of cities, and recreational site development. Each of these activities can include clearing vegetation, construction, transportation for construction and ongoing activities, and maintenance. Therefore, they have the potential to introduce or spread invasive plants in an area and would need to be considered in the project analysis.

Changes in Southeast Alaska's climate (discussed in the *Climate and Air* section of this chapter) could also create the conditions that encourage the spread of invasive plants by altering opportunities for invasive plants to colonize new areas, where could be compounded by climate change. Changing climate may also result in range extensions for some species that are native at more southerly latitudes, and they may become established or become more widespread on the Tongass, as a result. Changes in growing conditions would likely favor some plant species and stress others. There is uncertainty in the effect of changes in the climate to the invasive plants on the Tongass.

Forest Health

Affected Environment

Current Situation

Insects, diseases, related decay processes and windthrow are an integral and natural part of forest ecosystems. Many of these appear to play key roles in gap-level disturbance (see discussion of old-growth forests in the *Biodiversity* section of this chapter) and in providing wildlife habitat. The majority of the forests on the Tongass are old-growth forests. Losses to the timber resource caused by heart rot in live trees are considerable in old-growth forests. Approximately one-third of the volume of the old-growth hemlock-spruce forests in Southeast Alaska is decayed by heart rot fungi (USDA Forest Service and ADNR 2007).

In addition to heart rot, some of the more common destructive insects, diseases, and conditions within Southeast Alaska are listed below.

Black-Headed Budworm, *Acleris gloverana* (Walsingham), is one of the more destructive forest insects in coastal Southeast Alaska. In 1993, a peak year for budworm, approximately 258,000 acres of spruce-hemlock forests were affected. This was the largest outbreak in decades. In the 1950s, almost one-third of the net timber volume was lost on many hemlock sites due to budworm defoliation (USDA Forest Service and ADNR 2000). Black-headed budworm populations are currently at endemic levels, with less than 1,000 acres of mapped defoliation in the last 3 years (USDA Forest Service and ADNR 2007). Larval feeding strips hemlock foliage and can cause growth reduction, top-kill, and, at times, tree mortality (USDA Forest Service and ADNR 2000). Juday et al. (1998) rated many potential impacts on the coastal forests of Southeast Alaska due to climate change. They concluded that there was a high risk of increased damage from black-headed budworm outbreaks.

Hemlock Sawfly, *Neodiprion tsugae* (Middleton), is a serious defoliator of western hemlock throughout Southeast Alaska. Outbreaks tend to be of longer duration in southern Southeast Alaska where widespread damage is usually confined to the area south of Frederick Sound, especially along Clarence Strait. Larvae feed on mature (older) needles rather than current year (new) foliage. Most sawfly outbreaks do not cause tree mortality, but the tops are killed in some trees and tree growth may be reduced. Heavy defoliation by hemlock sawflies is known to reduce radial growth and cause top kill. No hemlock sawfly defoliation was mapped in 2006 (USDA Forest Service and ADNR 2007).

Spruce Beetle, *Dendroctonus rufipennis* (Kirby), is the most destructive forest insect Alaska-wide, although outbreaks in Southeast Alaska are typically smaller and of shorter duration than those in south/central and interior Alaska. Most outbreaks originate in blowdown or in cull logs left in harvest units and spread to adjacent standing timber. Mortality in unmanaged Sitka spruce stands varies and can be as high as 75 percent. Weather conditions appear to play a role in the expansion or contraction of beetle populations. Spruce beetle activity has been noted across the Tongass National Forest and adjacent lands from Yakutat Forelands to Dall Island (USDA Forest Service and ADNR 2000). Spruce beetle activity in 2006 centered on a 4,000-acre area between Haines and Skagway (USDA Forest Service and ADNR 2007).

Spruce Needle Aphid, *Elatobium abietinum* (Walker), is an introduced species that feeds on the needles of Sitka spruce, often causing reduced growth and increasing susceptibility to other mortality agents such as spruce beetle. As with other insect pests, populations have cycles, generally increasing following mild winters. More than 25,000 acres of spruce forest were defoliated in the winter of 1991 to 1992 (USDA Forest Service and ADNR 2000). The current outbreak began in 1998, with the worst defoliation occurring in 2003 when more than 30,000 acres were affected. Defoliation by spruce aphids affected approximately 9,120 acres in 2006, mostly in small pockets within the beach fringe from Lynn Canal in the north to Dall Island in the south (USDA Forest Service and ADNR 2007).

Hemlock Dwarf Mistletoe, *Arceuthobium tsugense* (Rosendhal, G. N. Jones), is a parasitic flowering plant that infects western hemlock throughout Southeast Alaska as far north as Haines. Infestation levels vary—dwarf mistletoe is absent in some stands, while almost every hemlock is infected in other stands. The upper elevational limit for Hemlock dwarf mistletoe in approximately 500 feet (Shaw and Hennon 1991). Volume growth in western hemlock trees heavily infected with dwarf mistletoe can be reduced by 39 percent or more (Thomson et al. 1985). In addition to reduced stem growth, infestations cause increased growth and retention of lower branches and distortation and weakening of wood strength at and near swellings. The spread of dwarf-mistletoe in young hemlock stands can result from leaving standing infected hemlock in harvest units (Laurent 1974). Dwarf mistletoe responds to light with increased seed production. Rates of spread to adjacent and lower canopy trees may increase in partial cuts where infected hemlocks remain. Trummer et al. (1998) developed a model for dwarf mistletoe infections in uneven-aged forests of Southeast Alaska that suggests infection rates are significantly correlated with levels of dwarf mistletoe infection in the residual trees. Deal (2001) reports partial cutting resulted in maintaining mistletoe levels at generally undamaging levels, with a trend towards less mistletoe in stands with higher harvest levels. A recent study of partial cut stands in British Columbia found that most young trees infected with mistletoe were advanced regeneration established before logging (Muir 2006).

Alaska Yellow-Cedar. Decline and mortality of yellow-cedar continues to be one of the most widespread and important forest problems in Southeast Alaska. Aerial surveys have mapped approximately 500,000 acres of decline in a wide band from western Chichagof and Baranof Islands to the Ketchikan area (USDA Forest Service and ADNR 2007). This decline is associated with wet, poorly drained sites, and recent research has demonstrated that no organism is the primary cause of the decline (Hennon and Shaw 1997). Hennon and Shaw suggest that reduced snow pack in low-elevation areas associated with a warming trend that started in the 1800s has exposed fine surface roots to freezing, which in turn kills trees. As the climate continues to warm, cedar decline is likely to continue to spread, especially in the south and east. Conversely, yellow-cedar appears to be spreading northward as climate warms, into areas that retain snow longer into the spring.

Hemlock Fluting. Hemlocks with fluting have deeply incised grooves and ridges extending vertically along their trunks, a condition that reduces the value of hemlock logs because they yield less sawlog volume and some of the milled wood contains bark. Fluting is a common problem in Southeast Alaska, especially on mid- to high-quality sites at low elevations, on gradual slopes, and with western exposure (Julin et al. 1993). It is rarely found away from the coast. The cause of fluting is not completely understood, but it may be associated with increased wind firmness, especially on shallow soils, due to growth increases triggered by silvicultural treatments or natural disturbance (USDA Forest Service and ADNR 2007). Julin et al (1993) found that the larger buttresses were generally aligned with the direction of the tree lean. They also concluded that western hemlock trees in Southeast Alaska may be genetically predisposed to form fluted trunks. Silvicultural treatments that favor other species and reduce branch size and retention period would greatly reduce fluting (Julin et al. 1993). However, because fluting primarily occurs in the beach buffer, the effect on timber resources is limited.

Decays. Stem decays cause substantial loss in all tree species in unmanaged stands. Tree death and stem breakage resulting from decay contribute to the structural diversity in stands and may be a major factor in small-scale disturbance in Southeast Alaska (Hennon and McClellan 2003). Many decay fungi enter through tree wounds. The accidental wounding of trees during partial cuts and commercial thinnings can increase the impact from decay organisms in managed stands (USDA Forest Service 1997a, Appendix G). However, Christensen et al. (2002) found very low levels of disease-caused defects in both thinned and unthinned 90-year-old hemlock-Sitka spruce stands on the Tongass compared to old-growth forests. Juday et al. (1998) rated many potential impacts on the coastal forests of Southeast Alaska due to climate change. They concluded that there is a risk that new fungal tree diseases will appear in Southeast Alaska as the climate warms.

Animal Damage. Significant animal damage to trees is apparent at various locations across the Tongass National Forest. Porcupine feeding on hemlock and spruce is common on Mitkof Island and many mainland areas. Young trees in managed and unmanaged stands are often top-killed or killed outright as porcupine feeding girdles the main bole. Bark beetles have been found infesting damaged trees. This damage becomes significant when groups of trees are killed or deformed. As trees grow larger (age 40 to 50 years), porcupine damage shifts from top kill to basal wounds, which serve as entry points for decay fungi. Brown bears cause basal wounds on Alaska yellow-cedar each spring on Baranof and Chichagof Islands. Bears rip off the bark in the spring to lick the sweet cambium. The majority of yellow-cedar in some stands have basal wounds from bear feeding (ADNR 2000).

Fire. Fire has played a minor role in the forests of Southeast Alaska because of the abundant year-round precipitation. The average size of fires on the Forest between 1958 and 1988 was less than 7 acres (USDA Forest Service 2003b). More recently, approximately 400 to 500 acres have burned annually on the Tongass. The average fire has been approximately 10 acres (pers. com. Dexter Duehn, Fire Management Officer, Tongass National Forest). Juday et al. (1998) rated many potential impacts on the coastal forests of Southeast Alaska due to climate change. They concluded that there would be an increased risk of forest fires, though they anticipated the effects on resources would be low.

Windthrow. Windthrow is the dominant disturbance agent in Southeast Alaska. Two forms occur: small-scale events (gap disturbance) and large-scale events (catastrophic disturbance). Most of the Forest is subject to small-scale windthrow events. Individual trees or small groups of trees blow over during storm events, opening gaps in the canopy that allow young trees to grow to fill the openings. This results in complex, mixed-aged stands. Disease and decay agents also play a role in this process. Nowacki and Kramer (1998) state that diseased trees are more at risk to windthrow and stem-snap, while Hennon and McClellan (2003) report that many of the uprooted or broken-stemmed trees had died before falling. Small-scale events occur on a regular basis and result in openings from 6 to 13 percent on the canopy (Nowacki and Kramer 1998). Areas not protected by topographic barriers from the severe effects of infrequent, major storms are subject to large-scale windthrow events that cause catastrophic damage. Entire stands have been blown down in the past, resulting in the regeneration of more even-aged stands with more uniform canopies (Nowacki and Kramer 1998). Both forms of windthrow are a part of the natural forest generation, growth, and development. Juday et al. (1998) rated many potential impacts on the coastal forests of Southeast Alaska due to climate change. They concluded that there was a high risk of increased large-scale blowdown across Southeast Alaska as well as increased windthrow around harvest units.

Monitoring and Pest Management

Forest pest activity on the Tongass National Forest is typically detected during on-the-ground activities, or during annual aerial surveys conducted by the region's Forest Pest Management group. The timing of surveys coincides with foliage and pest development. Pest activity noted during surveys is documented and reported to the appropriate land manager. In cooperation with land managers, Forest Pest Management people conduct on-site investigations to verify the pest, evaluate the pest and its host(s), and formulate future management alternatives. Often, pest and host monitoring is required to fully understand potential impacts prior to development of management alternatives.

Populations of historically significant defoliating insects are monitored through a sampling system that occurs in conjunction with the annual aerial survey. Defoliating larvae are collected, identified, and counted at designated sites. Gypsy moth pheromone traps have been placed throughout Southeast Alaska to provide an early warning that these insects are present. Data from larvae counts and pheromone traps, in conjunction with the collection of host and weather information, enhances forest pest managers' ability to predict defoliator damage.

The impact of hemlock dwarf-mistletoe and methods of reducing damage from the disease in managed stands have been established by several research studies. In addition, Forest Pest Management has surveyed numerous even-aged stands from 10 to 100 years old to determine the incidence and impact of hemlock dwarf-mistletoe in managed stands.

Research studies have yielded information on the pathology and epidemiology of decline of yellow-cedar (cited above). In addition, information on the distribution of decline and acreage affected has been determined by mapping during aerial surveys. Porcupine damage in managed stands is currently being assessed. As more young-growth stands reach commercial thinning age, forest pest research is beginning to focus on pest activity within these stands.

The Forest develops site-specific prescriptions, based on monitoring information, scientific information, and pest management projections, to prevent or limit insect and disease damage. The objective is to limit infestations of natural insects, disease-causing organisms, and parasites to normal background levels, and to prevent or reduce infestations of non-native organisms to the extent feasible. Similarly, the Forest objective is to limit windthrow to levels that would occur naturally through silvicultural prescriptions prepared for each timber sale.

Environmental Consequences

Direct and Indirect Effects

In general, alternatives that favor low amounts of timber harvest will tend to perpetuate current disease levels in old-growth forests. Ecological processes and wildlife habitat for old-growth associated species would be maximized, but so would the continued loss of timber, primarily due to high levels of heart rot. Higher amounts of timber harvest would generally yield young stands with lower levels of insect and disease activity. However, two-aged and uneven-aged management, primarily used in the Scenic Viewshed LUD, could maintain or even increase levels of hemlock dwarf mistletoe. Two-aged and uneven-aged management may also result in higher levels of stem and root disease caused by injuring residual trees during harvest operations; however, the degree of increase, if any, is uncertain. Two-aged treatments that clump leave trees are less likely to cause damage to residual trees. Similarly, thinning young, even-aged stands may also lead to stem and root disease due to wounding of leave trees during thinning, although a retrospective study did not find that thinning had increased defect levels in thinned stands on the Tongass compared to unmanaged stands (Deal et al. 2002), and Christensen et al. (2002) did not find higher levels of decay in two 90-year old stands that had been commercially thinned 25 years earlier compared to unthinned stands.

Alternative 7 proposes approximately three times the suitable acres as Alternative 1, and Alternatives 4, 5, and 6 propose approximately twice the number of suitable acres as Alternative 1 and substantially more than Alternatives 2 and 3. Most suitable acres would be harvested at some time during the next 100 years (refer to the *Timber* section for a discussion of likely harvest under each alternative). Therefore, over time, Alternatives 7 and 4 and, to a lesser extent, Alternatives 5 and 6, are likely to result in more acres with a lower risk of insect activity and somewhat less forest with high levels of heart rot and other disease organisms than the other alternatives. Conversely, Alternatives 1 and 2 would retain more acres of old-growth forest, which would likely result in somewhat higher levels of insect and disease across the Tongass. The acres of suitable land proposed for Alternative 3 is intermediate between Alternatives 2 and 5, and its effects on insect and disease would likely fall in the mid-range, compared to the other alternatives.

Alternatives 4, 5, 6, and 7 could result in approximately four to ten times as many acres of two-aged and uneven-aged harvest over time as Alternatives 1 and two to four times as many acres as Alternative 2 in the first decade (Table 3.8-1). There is some concern that two-aged and uneven-aged harvest could lead to higher levels of windthrow, dwarf mistletoe, and stem decay compared to even-aged harvest methods. Dean et al. (2002) report that the number of uprooted trees was somewhat higher in partially harvested stands, but overall tree mortality rates were similar. Bole wounds were common on trees in partially harvested stands, but “natural tree injuries from falling trees and animal feeding were far more abundant at several sites” (USDA Forest Service and ADNR 2002). Alternatives with more two-aged and uneven-aged management may favor shade-tolerant species (western hemlock, mountain hemlock, and yellow-cedar), while even-aged may result in stands with a higher proportion of Sitka spruce. However, retrospective studies indicate that Sitka spruce can be maintained in mixed hemlock-Sitka spruce stands over a wide range of cutting intensities if enough Sitka spruce trees are present in the stand after harvest (Dean 2002).

Table 3.8-1
Approximate Projected Annual Harvest During First Decade (acres)

	Alternative						
	1	2	3	4	5	6	7
Even-aged	1,180	3,674	5,181	7,308	6,872	6,769	10,030
Two-aged and Uneven-aged	602	1,586	2,193	3,957	3,028	2,859	5,902

Source: SPECTRUM Model (Forest-wide Activity and Output Results)

In general, endemic levels of insect and disease activity in mature and overmature forests would be allowed to run their course under all alternatives. Harvesting flexibility would be maintained to take advantage of timber salvage opportunities, particularly for dead and dying yellow-cedar stands. Insect and disease suppression may be justified in high-quality, mature to overmature stands that cannot be salvaged immediately, or that lie near recreation areas and communities where scenic values are high.

Animal damage, such as that from porcupines, is expected to continue and would likely be increasingly evident in precommercially thinned stands where porcupines are present. Winter feeding by porcupines is known to damage and sometimes kill young trees. The Forest has been alternating precommercial thinning prescriptions to reduce porcupine damage by favoring cedar and deferring thinning in some areas. Bear also damage young trees by removing bark to reach the sweet cambium tissue below the bark. Alternatives that result in creating more young stands (Alternatives 4, 5, 6, and 7) would lead to more acres of forest that would be vulnerable to animal damage.

Damage from wind would continue to occur; some increase is likely to occur along the edges of harvest units and along stream buffers and other legacy trees. Riparian buffers would be protected under Alternatives 1 to 6 by leaving sufficient additional trees along the outer edge of the stream buffer to provide a reasonable assurance of a windfirm (RAW) buffer. Riparian buffers on Class I and II streams would be protected by RAW buffers under Alternative 7. Alternatives with more harvest and road building (Alternatives 4, 5, 6, and especially 7) would tend to increase the risk of harvest- and road-related windthrow compared to those with less harvest and road building (Alternatives 1 and 2). If the current climate trend continues and more gale-force wind storms occur, blowdown may increase for all alternatives in proportion to the amount of harvest (refer to the *Timber* section of this chapter).

There may be a short-term increase in fire risk during harvest operations if activities are conducted during dry periods. Alternatives with higher levels of timber harvest (Alternatives 4, 5, 6, and 7) may have a small increase in fire risk compared to alternatives with less harvest. If climate change results in warmer, dryer summer conditions, fire risk may increase for all alternatives compared to the last several decades. Warmer winters are likely to increase insect damage because more insects will survive the winter. This, in turn, could lead to larger and more frequent fires (refer to the *Climate and Air* section of this chapter).

Cumulative Effects

The greatest potential forest insect and disease problems are likely to be in mature and overmature stands where disease levels are high. Tree vigor tends to decrease with maturity, causing an increase in susceptibility to insects and diseases. Heart rot levels are directly proportional to both tree and stand ages. The spruce beetle has the potential to significantly alter the desired condition of stands in certain locations near the mainland where the insect has periodically become active. The spruce aphid was introduced approximately 80 years ago and appears to be causing more damage to spruce as the climate warms (Shrader and Hennon 2005). The recent assessment of invasive pathogens in Alaska and its national forests states that Alaskan forests are particularly vulnerable to invasive pathogens because of the relatively small number of native tree species and the narrow genetic base (Shrader and Hennon 2005), although damage in 2006 was down 60 percent from the peak in 2003 (USDA Forest Service and ADNR 2007). The Shrader and Hennon report concluded that the European scolytid bark beetle poses the greatest threat to the spruce forests throughout Alaska if introduced.

Stem and root decay, and the incidence of hemlock dwarf-mistletoe, have historically increased with intensified land management activities, particularly under harvesting systems other than clearcutting (Trummer et al. 1998). If the current warming trend continues, cedar decline and damage from insects are likely to increase, both from species currently present in Southeast Alaska and from entering the area from other parts of North America or elsewhere. Hotter, dryer summers could also lead to increased fire frequency, size, and damage, which could have fundamental changes in age class and species composition. This, in turn, could result in changes in wildlife habitat. Invasive plants may also adversely affect forest health. Refer to the *Plant* section of this chapter for a discussion of invasive plant species.

There have been approximately 767,000 acres of harvest in Southeast Alaska, approximately 41 percent of this has been on non-National Forest System (NFS) lands. There are over 330,000 acres of old-growth forest on state and Native corporation lands. It is likely that most of this would be harvested over the next few decades and replaced with young stands that would be managed on relatively short rotations. Shorter rotations and even-aged silvicultural prescriptions implemented on non-NFS lands are likely to contribute to decreasing mistletoe, insect, and disease levels in the forests of Southeast Alaska, especially the loss due to heart rot. Alternatives with more even-aged management, especially Alternatives 4 and 7, would add to these changes. Conversely, increased use of commercial thinning in the outer decades may damage leave trees, increasing decay rates. Also, the younger stands established after harvest on all lands are likely to add to the loss of growth and tree mortality caused by animal damage in the region. Harvest-related windthrow may increase on NFS lands and adjacent areas that are harvested using even-aged silvicultural systems whether on NFS or non-NFS lands.

Maintaining biotic and structural diversity provides an opportunity for limiting some insect and disease problems. Some insects and diseases are host-specific, depend upon plants that are under stress, or flourish under homogeneous conditions. In other cases, and particularly for heart rot, favoring younger-aged stands through even-aged management may be the most effective way of limiting insect and disease problems. Maintaining healthy young-growth stands through stand density control (thinning) may reduce insect damage (Neilson 2007).

The careful use of alternatives to even-aged harvest methods can be a tool for maintaining natural but not excessive levels of diseases, such as heart rot and dwarf mistletoe, which have important ecological consequences. Integrated Pest Management provides the opportunity to evaluate these and more traditional clearcut practices. Through prescription processes, stands with unacceptable insect and disease-related losses, as well as those of high risk for future losses, would be identified for treatment. Detection methods such as aerial surveys, currently in use, would continue to be used for the early identification of epidemics.

The current warming trend increases the risk of increased insect and disease outbreaks, catastrophic blowdown events, and fires. Juday et al. (1998) rated many potential impacts on the coastal forests of Southeast Alaska due to climate change. They concluded that there was a high risk of increased large-scale blowdown across Southeast Alaska and increased windthrow around harvest units; although, they also state that as of the date of their report, the increased frequency of storms in the last few decades has not corresponded to an increase in large-scale blowdown in Southeast Alaska. Also, the 2006 Forest Health report noted very little blowdown in aerial and ground surveys (USDA Forest Service and ADNR 2007); however, this does not rule out the risk of increased windthrow in the future as additional warming occurs.

Warmer, dryer weather may result in increased levels of insect and disease levels. For example, Juday et al. (1998) concluded that there was a high risk of increased damage from black-headed budworm outbreaks, and there is a risk that new fungal tree diseases will appear in Southeast Alaska as the climate warms.

As discussed under the *Climate and Air* section, some climate models for Southeast Alaska predict rising temperatures, a 10 percent decrease in summer precipitation in portions of the region, and decreased soil moisture due to increased evaporation during warmer, dryer summer weather. These factors may lead to an increase in fire frequency and severity by 2060, ranging from 10 to 30 percent, depending on the model (Dale 2003). Currently, fire is not a factor in the ecology of Southeast Alaska, and an increase of 30 percent in acres burned would still result in very little fire damage. Given the high rainfall levels in Southeast Alaska (Ketchikan had only 2 days without rain in July 2007, receiving a total of 10 inches of rain that month), a 10 percent decrease in summer rainfall would still result in wet conditions in most years. However, Southeast Alaska does occasionally experience dryer conditions. For example, in July 1971 there were 23 days without rain. If warmer winter weather results in higher insect populations and increased tree defoliation, there is a risk that increased dead material and warmer, dryer weather may spawn more fires than are normal for the area. Berman et al. (1998) state that it is difficult to predict the magnitude of area likely to be burned in a region with no historic fire record, but they believe that most fires would be small and of low intensity. Berman et al. (1998) suggest a scenario in which 5,000 acres might burn over a period of decades. Juday et al. (1998) also suggest that the effects of fires on resources are likely to be low.

Biodiversity

Affected Environment

The conservation of biological diversity, or biodiversity, is of national and global concern. Biodiversity may be defined as “The variety of and variability within and among living organisms and the ecological complexes of which they are part; this includes diversity within species, between species, and of ecosystems.” (United Nations Environment Programme 1991). Biological diversity encompasses the variety of genetic stocks, plant and animal species and subspecies, ecosystems, and the ecological processes through which individual organisms interact with one another and their environments. Under the National Forest Management Act (NFMA), the Forest must provide for diversity of plant and animal communities based on the suitability and capability of specific land areas.

The conservation of biological diversity commonly requires a dual strategy addressing both individual species, as well as entire ecosystems (Marcot et al. 1994). Many discussions of biodiversity revolve around the maintenance of species; however, it must be emphasized that conserving biodiversity is about maintaining genetic, species, community or ecosystem, and landscape levels of biological organization. The traditional species-by-species approach is important for featured or management indicator species, sensitive or rare species, and for the recovery of federally designated threatened or endangered species. A more comprehensive strategy focused on higher levels of biological organization, and ecosystems may be necessary to conserve rare or declining habitats, as well as the entire complement of associated biota and ecological processes (Noss 1991, Scott et al. 1991, Franklin 1993). For a conservation strategy targeting biodiversity to be truly effective, it should have the following characteristics or expected outcomes:

- It should include the conservation of all levels or scales of biodiversity in the planning area (Schwartz 1999, Poiani et al. 2000),
- It should be comprehensive in its inclusion of all elements (Lambeck and Hobbs 2002, Groves 2003),
- It should address the concept of adequacy (Lambeck and Hobbs 2000, Tear et al. 2005),
- It should provide a framework for monitoring (Haufler et al. 2002, Tear et al. 2005), and
- It should anticipate change (Tear et al. 2005).

Maintaining and/or enhancing habitats to sustain viable populations of individual species are addressed by guidelines for specific species or species groups. This "fine filter" approach to biological conservation is discussed in the Wildlife, Fish, and Plant sections of this chapter. The most practical way to address conservation of these species and other elements of biodiversity is by using a broader “coarse filter,” or ecosystem/landscape-based strategy for conserving biological diversity (Noss 1991, Scott et al. 1991, Wilcove 1993). While many conservation planning efforts blend the two strategies, it is important to note that there are fundamental differences between these conservation strategies. Fine filter strategies focus on providing for the needs of individual or multiple species within a landscape while coarse filter strategies focus on providing an appropriate mix of ecosystems or ecological communities across a planning landscape (The Nature Conservancy 1982, Marcot et al. 1994, Haufler 1999, Schwartz 1999).

Biological diversity on an ecosystem or landscape scale can be described in terms of three components: composition, structure, and function (Noss 1990). These three components refer to the following:

- Composition refers to the numbers and types of species, plant communities, and smaller ecosystems within an area.
- Structure refers to the spatial arrangement of these communities or ecosystems across a landscape, their vertical stratification into dominant life forms (tree, shrub, herbaceous), the horizontal spacing of communities across the landscape, and how they are connected to variations in tree heights and diameters within a stand or between stands.
- Function refers to the interactions and influences between plant and animal species within an area—how each species uses its environment—and to natural processes of change or disturbance (wind, aging, etc.).

For additional discussion on composition, structure, and function components of biological diversity, see the 1997 Forest Plan Final EIS (pages 3-12 to 3-26).

Assessing biodiversity and the conservation strategy to provide viable, well distributed populations across the Tongass National Forest has been conducted at several scales from broad biogeographic provinces down to finer scales of ecological subsections, watersheds, and Value Comparison Units (VCUs). Assessing biodiversity at smaller scales such as at watershed and VCU level is done at the project-level scale. The biogeographic province and ecological section/subsection are discussed in more detail below, with the focus on maintaining biodiversity across the entire Tongass.

Ecosystem Classification

Utilizing both biogeographic provinces and ecological subsection classifications allows for some additional insight into how various communities are represented at different landscape scales. Both classification systems were developed using different processes, but complement each other in terms of addressing biodiversity. The development of biogeographic provinces is weighted more heavily toward wildlife species distributions, including barriers and linkages, while the ecological section/subsection system is more heavily weighted toward surface geology and geomorphic processes, both of which affect soils and vegetation patterns. Both of these broad-based “coarse filter” classification systems are described in more detail below.

Biogeographic Provinces

The Tongass can be subdivided on an ecosystem basis. A broad division that has been used on the Tongass for a number of years is that of the biogeographic province (USDA Forest Service 1997a). These large-scale landscape delineations are characterized by 1) similarities in terrestrial wildlife species composition, 2) similarities in distributional patterns for many of these species, 3) geologic and water barriers stemming from past events, such as glaciation, and 4) generally similar climatic conditions and physiographic characteristics. By subdividing on this scale, biogeographic provinces can assist land managers in broad-level assessment and planning.

Twenty-one biogeographic provinces were identified within the Tongass National Forest boundary. Only one of these provinces (Yakutat Forelands) extends partially outside the boundary. Two additional provinces (Chilkat River Complex and Glacier Bay/Fairweather Range) are defined completely outside the Forest boundary but within Southeast Alaska (Table 3.9-1). Figure 3.9-1 shows the location of the biogeographic provinces in Southeast Alaska with their corresponding map numbers.

Ecological Sections and Subsections

In addition to the biogeographic province approach, another way to address conservation of species and other elements of biodiversity with a “coarse filter” or ecosystem/landscape-based strategy, is to use the National Hierarchical Framework of Ecological Units, which describes and defines the process for delinating landscapes at various spatial scales. This process consists of eight nested mapping levels that serve a variety of purposes (Cleland et al. 1997). Within the hierarchy, ecological sections characterize medium to large ecosystems (on the order of 1,000 square miles) and ecological subsections characterize mid-sized ecosystems of 10 to 1,000 squares miles. Nowacki et al. (2001) used this framework to subdivide the Alaska Region into 19 ecological sections and 96 ecological subsections; 14 of the ecological sections and 73 of the ecological subsections occur on the Tongass.

Nowacki et al. (2001) provide additional detail on the ecological sections and subsections of the Tongass. Physiography, lithology, and surface geology were the primary factors for subsection delineation in Southeast Alaska, along with geomorphic processes, soil groups, subregional climate, and potential natural communities (climax vegetation). They are delineated in Figure 3.9-2 and listed later in this section under Table 3.9-6.

Table 3.9-1
Biogeographic Provinces Identified within the Tongass National Forest

No.	Province	Description
1.	Yakutat Forelands	A very young, nearly flat landscape with extensive flooding and active isostatic rebound (uplifting of the ground after glaciers recede). Most surfaces vary from 200 to 1,500 years old. Dune formation and succession are ongoing processes due to glacial rebound and wave action. Plant community patterns reflect a diverse mosaic of naturally occurring older and young forests, shrublands, bogs, and meadows. Sitka spruce, alder, and cottonwood are abundant on well drained, recently deglaciated, and active fluvial surfaces. Most of the province is inside the Tongass Forest boundary, but the southern lobe that extends into Glacier Bay National Park is not.
2.	Yakutat/ Glacier Bay Upland	The climate varies from very wet hypermaritime along the coast to very wet maritime inland. Mountains abruptly rising more than 10,000 feet from sea level, extensive active glaciers, and fiords dominate this landscape. Sitka spruce, alder, and cottonwood are abundant at lower elevations; alpine and lichen over rock plant communities dominate the land from 2,000 to over 10,000 feet elevation.
3.	East Chichagof Island	This province is drier and colder than the outer coast of Chichagof Island; the winter snow pack is generally greater. Chichagof Island is deeply dissected into three peninsulas, which may be functioning biologically more like separate islands. Vegetation in this province represents a modal condition similar to the Admiralty Island Province.
4.	West Chichagof Island	This province is dominated by a very wet hypermaritime climate and exposure to outer coastal storms. Hundreds of small islands dot the coast. Topography is gentle when compared to the mountains of Baranof Island and the coastline is highly irregular. The Sitka spruce/Pacific reedgrass plant association is abundant along the outermost coastal fringe; otherwise, vegetation is similar to the other northern islands.
5.	East Baranof Island	This province is colder than West Baranof or East Chichagof Island. Mountain glaciers occur along the divide between east and west Baranof. Topography is rugged and steep to saltwater, with little flat land. Plant associations on East Baranof are similar to much of the mainland due to the steep topography and cold environment. Spruce, devil's club, salmonberry forest associations are common on avalanche and steep erosional slopes; alpine and rock/lichen plant communities are abundant.
6.	West Baranof Island	This province is similar to the West Chichagof Island Province with the exception of southern Baranof, where precipitation exceeds 250 inches per year. Topographically, Baranof Island is the most rugged of all the islands in Southeast Alaska. The southern half of this province is highly dissected by steep-sided fiords; the outer coast is dotted with hundreds of small islands. All forest plant associations except those in the Western redcedar series and those found around large mainland rivers occur in this province. Kruzof Island has some unique vegetation communities, which have not been classified.
7.	Admiralty Island	This province is represented by relatively gentle topography and moderate rainfall. Winter conditions are moderated by the surrounding marine environment. Winds from Chatham and Icy Straits, Lynn Canal, and off the mainland are often severe. All forest plant associations except those in the Western redcedar series, those found around large mainland rivers, and those occurring only on outer coastal areas occur in this province. Forest productivity is high. Fresh and saltwater marshes in the numerous bays and inlets, and alpine and bog communities, are abundant.
8.	Lynn Canal	Rain shadows and the dominating influence of the continental climate make this the driest and seasonally warmest province in Southeast Alaska. Precipitation is generally less than 60 inches per year. The topography is rugged and glaciated. The southern portion of the Chilkat Peninsula is more similar to the East Chichagof Island Province. Western and mountain hemlock and Sitka spruce plant associations are common. Alpine tundra and extensive rock/lichen communities dominate much of the land from 2,000 to over 8,000 feet elevation.
9.	Northern Coast Range	This province has little maritime influence. Topography is rugged and glaciated. The Taku and Whiting Rivers extend into Canada. Yellow-cedar plant associations occur in this province.
10.	Kupreanof/ Mitkof Islands	The climate is cooler and the winter snow pack greater than on the islands to the south. The eastern edge of this province is strongly influenced by wind-born loess (silt) coming from the Stikine River and the mainland. All forest plant associations except those in the Western redcedar series and those occurring only on outer coastal areas occur in this province. This province contains the highest percentage of muskeg wetlands within the Tongass.
11.	Kuiu Island	Kuiu Island is deeply dissected, creating several prominent peninsulas. The topography is gentle compared to neighboring Baranof Island or the mainland. The climate is cooler and winter snow pack greater than on islands to the south, yet milder than the mainland or islands nearer the mainland. The western portion of Kuiu Island is subject to severe windstorms from both the ocean and Chatham Strait. Most forested plant associations occur here, but those found in outer coastal environments dominate.

Table 3.9-1 (continued)
Biogeographic Provinces Identified within the Tongass National Forest

No.	Province	Description
12.	Central Coast Range	This province is warmer than the Northern Coast Range Province. The topography is similar, but overall less precipitous. The Stikine River system is located in the center of this province and has a major continental influence, providing a migration corridor for plant and animal species. Plant associations found along saltwater are similar to those occurring elsewhere in northern Southeast Alaska except for those near the mouth of the Stikine River. Here, unique plant associations subject to high loess-carrying winds can be found.
13.	Etolin Island and Vicinity	Similar to the Kupreanof/Mitkof Islands Province, this province is also subject to continental influence from the mainland and the Stikine River. Glacial flour (very finely ground particles of rock, silt, or clay created by a glacier when its rock-filled ice scrapes over bedrock and which flow out from beneath a glacier in the meltwater) is present in the marine environment in the northern part of this province nearly year-round. All forest plant associations except those occurring only on outer coast areas are present.
14.	North Central Prince of Wales Island	Topography is relatively gentle, limestone is common, and precipitation is relatively low due to interception by lands to the south and southwest. All forest plant associations except those found around the mainland river systems occur in this province. Overall forest productivity is high. Karst topography and numerous caves are present.
15.	Revilla Island/ Cleveland Peninsula	Climate is variable with warm and wet conditions predominating on land nearest the outer coast; much colder conditions occur near the mainland. Revilla, Gravina, and Annette Islands are influenced by human activities and populations, whereas the Cleveland Peninsula and Duke Island are generally in a natural condition. Revilla Island has many exceptional estuaries. Muskeg ponds are common on Duke Island, attracting many wintering and migratory birds.
16.	Southern Outer Islands	These islands are isolated and are subject to strong oceanic influences. Temperatures are moderate year-round. The topography is low-lying and gentle. These islands are relatively rich in endemic vertebrate species, including dusky shrew, long-tailed vole, and ermine. Major coastal seabird colonies are present.
17.	Dall Island and Vicinity	These islands are subject to strong oceanic influences. Temperatures are moderate year-around. The topography is rugged and dissected, with abundant limestone outcrops. Dall Island appears to be a glacial refugia but inventories of plants and animals are limited. Major coastal seabird colonies are present on Dall Island.
18.	South Prince of Wales Island	The climate is warm and wet, and deep snow is rare or highly transient. The topography is steep and rugged and the coastline is highly dissected. The vegetation in this province is strongly influenced by southeasterly storms; mixed conifer and western hemlock-redcedar plant associations dominate.
19.	North Misty Fiords	Compared to South Misty Fiords, this province has considerable topographic relief and characterized as having a colder, mainland-type climate with many glaciers. Vegetation occurs in long, narrow strips along the valleys and lower slopes of fiords. Much of the vegetation is muskeg, with cottonwoods in some of the river bottoms and subalpine fir along the Canadian border.
20.	South Misty Fiords	South Misty Fiords is typical of the other mainland provinces and is the warmest. Topographic relief is lower in comparison with North Misty. Forest plant associations are more diverse than the other coastal provinces, and the vegetation is less fragmented by rock and ice than in North Misty Fiords. The southwestern portion of this province is rolling, nearly continuous muskeg with conifer forests in the bottoms and flats. This province is the northern limit of Pacific silver fir, yew, and honeysuckle.
21.	Ice Fields	Permanent ice fields, active glaciers (some advancing and some receding), and nunataks (mountain peaks between glaciers) dominate this province.
22.	Chilkat River Complex	The Chilkat River Complex lies at the northern end of the Inside Pasage and is outside the Tongass Forest boundary. It consists of tall ridge systems, large glacial rivers, and includes glaciers and snowfields. Many of the rivers and drainage basins extend across the international boundary into Canada. Because of the overlap of coastal and interior floras and faunas, the province contains Alaska's highest vascular plant species richness and the highest mammalian diversity in Southeast Alaska (Carstensen et al. 2007).
23.	Glacier Bay/Fairweather Range	This is the largest province in Southeast Alaska (2.5 million acres) and is located outside the Tongass Forest boundary. The vast majority is high mountains and glaciers and the majority is non-vegetated. The highest peaks are in the Fairweather Range along the western edge of the province, with Mt. Fairweather at over 15,000 feet. A large flat, foreland, the Gustavus Foreland, occurs in the area around Gustavus and to the north in the Bartlett River valley. Lowlands are also fairly extensive along the Dundee River and other smaller drainages on the southwest side of Glacier Bay. Glacier Bay National Park protects virtually the entire province (97 percent), except for about 75,000 acres in the vicinity of Gustavus.

Figure 3.9-1
Map of Biogeographic Provinces of Southeast Alaska

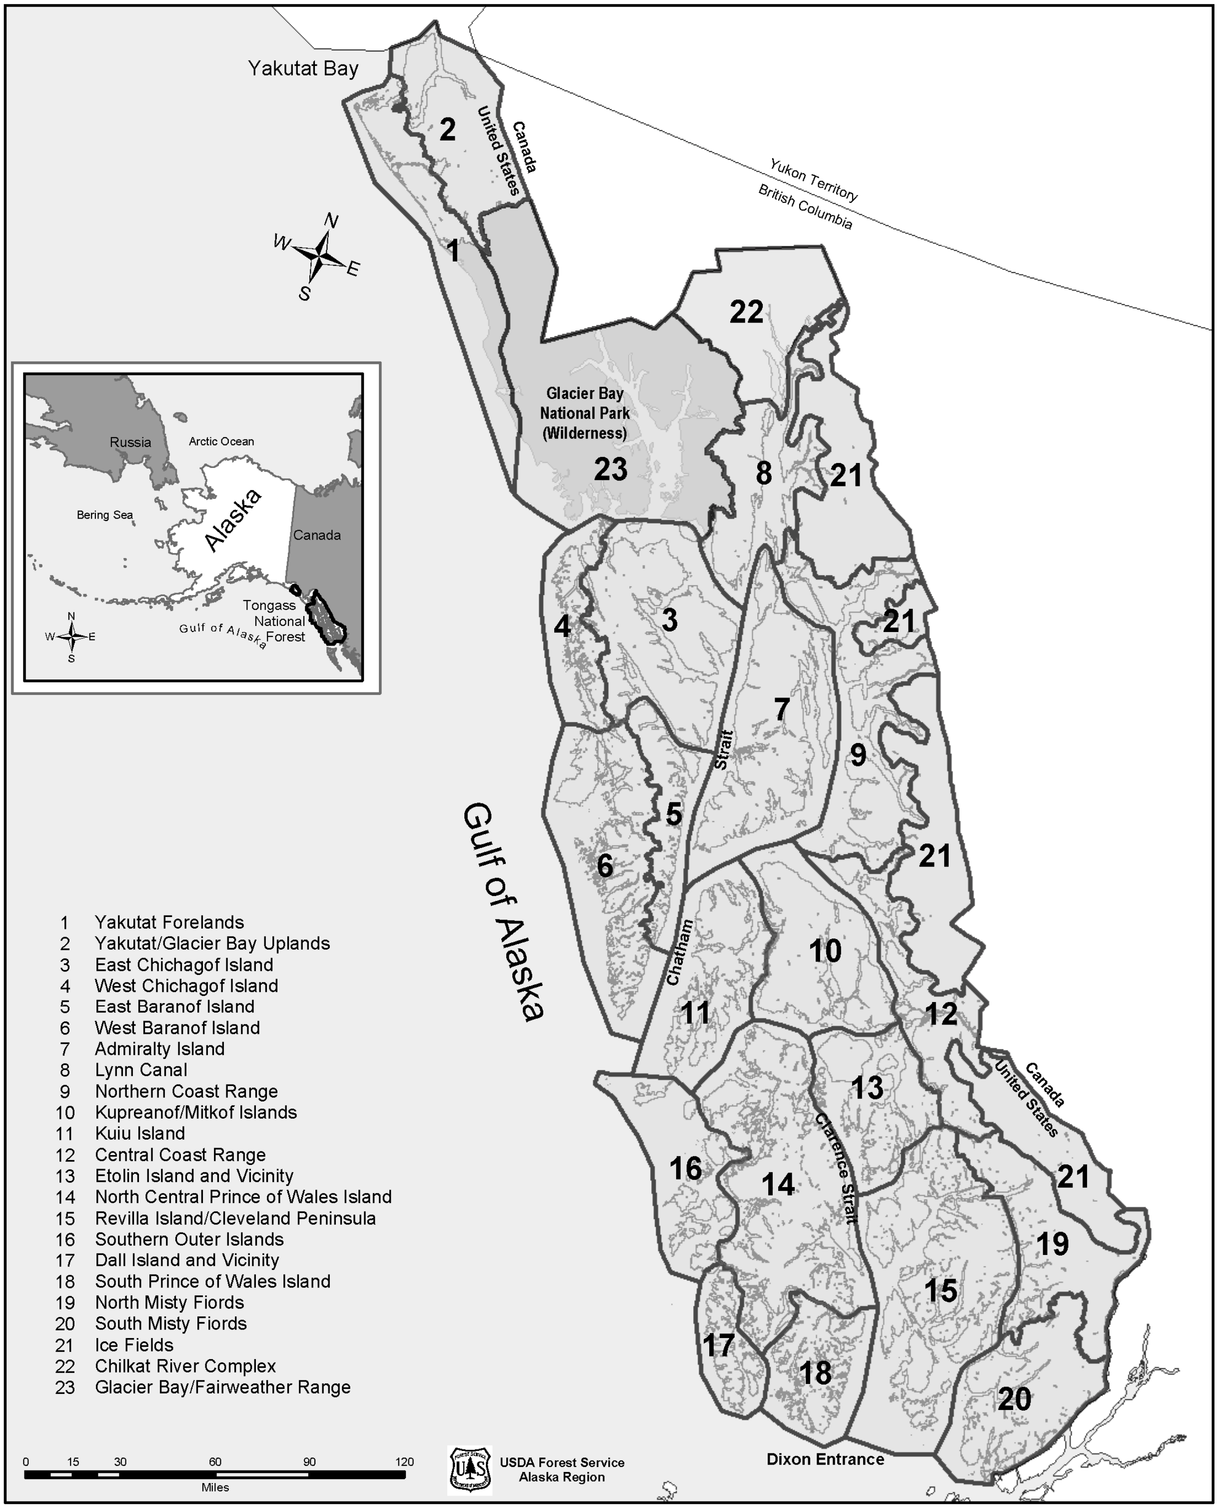

Figure 3.9-2
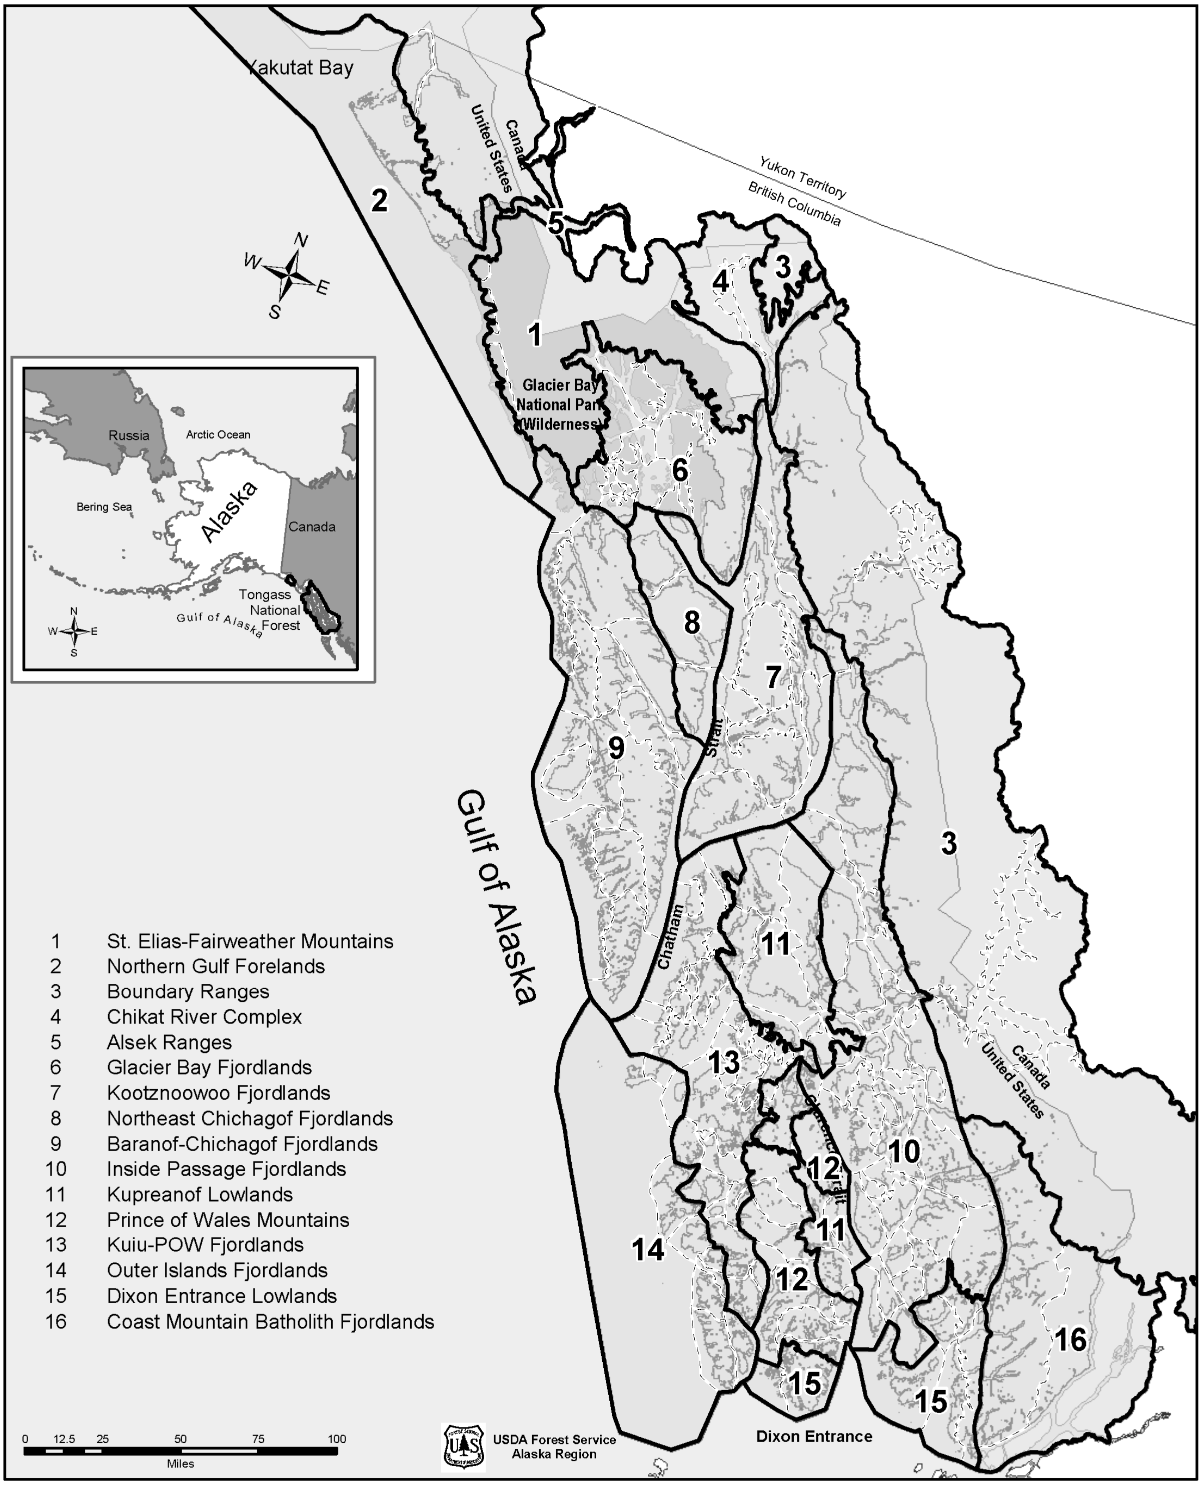
Ecological Sections (numbered areas) and Subsections (dashed lines) of Southeast Alaska



Cover Types

The vegetation of Southeast Alaska and the Tongass National Forest is dominated by temperate coastal rain forests at lower elevations (less than about 2,000 feet.). Interspersed within the forest are muskegs, other wetlands, and other nonforest types. At higher elevations, alpine vegetation, rock, glaciers, and snowfields dominate. Figure 3.9.3 displays a general breakdown of the broad cover types on the Tongass. Table 3.9-2 provides a summary of this breakdown by biogeographic province.

The Tongass contains approximately 9.9 million acres of forest lands (approximately 59 percent of the total land area of the Tongass National Forest). These forest lands are divided into productive and unproductive forest lands. Productive and unproductive forest lands are distinguished in terms of their ability to produce wood. The distinction is primarily used in timber management; however, it is useful for describing forest cover types for biodiversity and wildlife habitats as well. Productive forest land (5.64 million acres of the Tongass) is defined as land capable of producing at least 20 cubic feet of wood fiber per acre per year or having greater than 8,000 board feet per acre of standing volume. Unproductive forest land (4.22 million acres of the Tongass) is forest land that does not meet these thresholds. Timber harvest occurs only within the productive forest land base.

Of the 5.64 million acres of productive forest land on the Tongass, 4.95 million acres or 88 percent are old growth and are referred to as productive old growth (POG). The remaining 0.69 million acres are young-growth forest; about 0.45 million acres of the young growth is a result of timber harvest. The remainder of the young growth is a result of natural processes (e.g., wind, fire, glacial retreat).

The remaining 6.91 million acres of the Tongass National Forest (41 percent) is classified as non-forest and includes shrub and herbaceous habitats (e.g., muskeg, alpine, estuaries), sparsely vegetated and non-vegetated areas (e.g., snow, rock, ice), and aquatic habitats (e.g., streams, ponds, and lakes). These general cover types are further broken down and discussed in more detail below beginning with non-forested habitats and followed by unproductive old-growth and POG cover types.

Figure 3.9-3
General Cover Types on the Tongass National Forest

[1] Includes 454,724 acres of harvested young growth and 233,843 acres of natural young growth.
(Source: Tongass National Forest GIS databases)
Note: Totals may not appear to sum correctly due to rounding.

Non-Forest Lands

Non-forest ecosystems provide unique and valuable habitat types that include wetland and other areas of shrub and herbaceous types (e.g., muskegs, alpine, estuaries), non-vegetated areas (e.g., snow, rock, ice), and aquatic sites (e.g., streams, ponds, and lakes). These habitats contribute greatly to the species diversity on the Tongass National Forest by providing unique microsites and openings that contain shrub and herbaceous vegetation that is often uncommon elsewhere.

Approximately 41 percent of the Tongass is non-forested. Of the non-forest land area, over half (55 percent) comprises rock and ice/snow, followed by brush and alder brush (20 percent), alpine (8 percent), recurrent slide areas (6 percent), and wetland-meadow (4 percent) (Table 3.9-3). Approximately 0.5 million of the remaining non-forest acres (7 percent) include small amounts of mass wasting areas, uplifted beach, river fill, willow, sand dunes, urban/agriculture, and other types.

Unproductive Forest

Approximately 25 percent or 4.2 million acres of the Tongass are classified as unproductive forest. Approximately 25 percent of this habitat type is forested

Table 3.9-3
Non-Forest Cover Types on the Tongass by Biogeographic Province (thousands of acres)

		Non-Forest Lands

muskeg (Table 3.9-2). Although some of these lands are relatively sparsely forested, they have at least 10 percent tree cover. Many unproductive forest stands are consistent with old-growth definitions, but the trees are typically small and stunted (under 40 feet in height) and the canopy is open (10 to 40 percent canopy closure). Hemlock, cedar, and lodgepole pine are the most common trees; blueberry and rusty menzesia are the most common shrubs. Near wet bogs or muskegs, heath family plants and grasses assume increasing dominance. Timber harvest has had little direct effect on unproductive forest. Past disturbance to this habitat type has occurred in the primarily as a result of road construction, which has resulted in some permanent reduction in total wetland acres. This disturbance is discussed further in the *Wetlands* section. Unproductive forests are also addressed in the *Old-Growth Forest* subsection below.

Productive Forest

As noted above, the 5.64 million acres of productive forest land on the Tongass consists of both old growth and young growth. Approximately 88 percent of the productive forest land consists of old growth and approximately 12 percent is young growth, which includes both natural young growth and harvested areas.

Old-Growth Forest

POG forests are ecosystems distinguished by old and typically larger diameter trees, with most old-growth stands greater than 150 years old. At the landscape scale, old-growth forests on the Tongass include heterogeneous stands of productive forests within a mosaic of unproductive forests and non-forested areas comprised of shrub and herbaceous plant communities. These areas have been affected by various levels of natural and human-caused disturbances.

The biological diversity associated with old-growth forests has long been recognized as important within the Tongass National Forest, and the old-growth forest is the ecosystem most affected by timber management activities on the Tongass. Franklin (1993) estimated that invertebrate biota, creatures essential to ecosystem function through such processes as nitrogen fixation and decomposition, may represent more than 90 percent of the species diversity of old-growth forests in the Pacific Northwest. Because other habitat types (e.g., non-forested habitats) are fully represented across the Tongass and have not likely changed appreciably from original conditions, the old-growth ecosystem is the primary focus for the analysis of biological diversity in this document.

As described above, old-growth forests are divided into two major categories: POG and unproductive old growth. These are further divided on the basis of their productivity, defined in terms of their ability to produce a minimum volume of wood. The relative productivity of a stand is based on site quality. Site quality is defined as the ability of a forest site to grow trees (Carmean 1975), and is based on the physiography, climate, soil, and other factors of the environment that are not easily altered. Site productivity is the capacity of a tree species to thrive and successfully compete on a particular site and is influenced by the physiological makeup of the tree species and environmental factors (Pritchett 1979). Productivity measurements are most commonly based on site index values. Site index is expressed as the height of dominant and co-dominant trees at a given age, normally 50 or 100 years. Site index values for Southeast Alaska were determined by Farr (1984) by measuring the height and age of sample trees in a stand from standard site index curves projecting the height at the index age.

A higher site quality generally translates into taller trees and higher volume per acre. Higher site quality results in faster changes in tree characteristics and stand structure. Height to diameter ratios increase faster on high sites and live crown ratios will tend to decrease faster due to the affects of heavier stocking. Species composition is influenced by site quality. For example, Sitka spruce and western hemlock tend to have a greater competitive advantage on the high site quality areas while cedars are generally better represented on mid to lower site quality areas. Site productivity, a function of site quality, is highly correlated with soil drainage, effective soil depth, soil development (parent material), and landscape position (landform and slope position) (Cullen 1987). Site variation within stands can be significant. Typically, site productivity is highest in the valley bottoms decreasing with increased elevation.

The oldest harvests on the Tongass tended to be on the higher productivity sites at lower elevations, adjacent to the beach and within floodplain riparian areas where large Sitka spruce were available and abundant. These oldest young-growth stands are generally dominated by Sitka spruce and western hemlock regeneration. Road construction, started during the pulp mill era, allowed for harvest to be located farther away from the beach and riparian areas, although harvest during the early years was still concentrated at lower elevations. Old growth on limestone soils (which includes karst terrain) was also more heavily targeted. As a result of targeting highly productive and economical sites in the early years of timber harvest, larger-tree stands were often disproportionately harvested. Due to more extensive road development and restrictions brought about by development of a Forest Plan in 1979, stands harvested in the 1980s and especially in the late 1990s to the present tend to be located across a much more diverse range of sites.

Maintaining a full representation of ecosystem types is an accepted strategy for conserving biodiversity in landscapes managed for forestry (Franklin 1993), and is part of the overall conservation strategy implemented under the 1997 Forest Plan which includes small, medium, and large old-growth reserves and forest-wide Standard and Guideline protection measures. Most species, especially those for which knowledge is sparse or absent, are best sustained by ensuring that an adequate portion of each ecosystem type is represented in a relatively unmanaged state (Wells et al. 2003). Some specific types of old-growth forest ecosystems are at greater risk than others, such as forests associated with alluvial/colluvial surfaces or karst geology (USDA Forest Service 1999a, Baichtal and Swanston 1996). POG forest stands, particularly low elevation stands, have been affected the most by human modification through timber harvest.

Young-Growth Forest

As shown in Figure 3.9-3, there are approximately 689,000 acres of young-growth forest on the Tongass. Approximately 455,000 acres of POG have been harvested on the Tongass, nearly half of this amount is on land that is currently suitable for timber harvest. (See the *Timber* section for additional discussion on young-growth and suitability.) There are opportunities to manage these stands to increase biodiversity. Young-growth stands can be treated through release, pre-commercial thinning, and commercial thinning to concentrate growth in fewer, larger trees. Since 1979, over 100,000 acres have been pre-commercially thinned on the Tongass. These treatment methods have averaged about 5,600 acres per year in recent years and can be used to extend the period that understory forage is available for species such as deer, increase habitat for certain prey species, or promote conditions that mimic old-growth stand characteristics at a faster rate than would occur without treatment (USDA Forest Service 2000a, Carey 2003). Approximately 45 percent of the areas harvested on the Tongass are no longer suitable for commercial timber harvest because of their current land use designations, which include Wilderness, LUD II, 1,000-foot wide beach fringe, riparian areas, and old-growth habitat reserves. While these stands are not managed for timber production, they can still be thinned to improve wildlife habitat using the same treatments described above.

Old Growth Classification

For the 1997 Forest Plan, the Tongass classified POG on the basis of three volume strata (low, medium, and high volume). These were refined based on using the existing TIMTYP inventory, soils, and slopes. Since the issuance of the 1997 Forest Plan, several landscape and timber-sale analyses have effectively used the three broad timber-type categories delineating non-forest, unproductive old-growth forest, and POG forest lands, which were divided further into high-, medium-, and low-volume strata forest stands (see the Timber section in this chapter for additional discussion on timber volume class and volume strata).

Size-Density Model

While the three-volume strata approach for POG is useful for estimating timber volume for forest planning purposes, it is not as useful for describing other important forest elements, including forest structure, ecosystem diversity, and wildlife habitat. Forest structure is defined as the spatial arrangement of the components of vegetation, and is a function of tree size and height, vertical stratification into layers, and horizontal spacing of trees. It is important because it reflects the complex spatial and temporal interactions between plant growth (e.g., dispersal and competition), physiographic factors (e.g., geology, soils, slope, aspect, elevation), climate, and disturbance (e.g., wind, landslides, and human activities). Areas of high-structure habitat are typically located in areas of well-drained soils on unconsolidated sediments associated with alluvial fans, floodplains, or toe slopes.

Differences in forest structure are more useful because timber volume may be misleading when describing wildlife habitat or other attributes of the stand. For example, two stands may have the same volume but one may be a dense stand of medium-sized trees with a single canopy layer while the other stand may be a combination of widely-spaced large overstory trees and two or three lower canopy layers containing small and medium sized trees (Caouette et al. 2000, Caouette and DeGayner 2001).

To move beyond the limitations of timber volume, Forest Service managers and planners have begun to revise and refine forest mapping on the Tongass by creating a tree size and density mapping model for POG forests. Such information is more applicable for assessing conservation of biodiversity, estimating timber values, and developing wildlife habitat models.

One alternative to using volume estimates is using a combination of two common forest measurements: tree sizes and tree densities (Caouette et al. 2000). These two measures provide a more comprehensive forest measuring system than timber volume (Spies and Franklin 1991, Franklin 1995). The Forest Service recently published National Guidance on vegetation classification and mapping that specifically requires tree sizes (expressed as quadratic mean diameter of all live dominant/co-dominant trees) and tree densities (expressed as canopy closure) for the mapping of forest structure (USDA Forest Service 2004d). The Tongass National Forest recently developed an approach that uses these two measurements to model structural diversity in order to better define and describe forest structural attributes (Caouette and DeGayner 2005). The size-density model (SDM) uses a combination of two common forest measurements: tree sizes and tree densities (Caouette et al. 2000). This model has proven to be the best tool for representing these other forest elements.

SDM uses timber volume class, hydric soil class, and aspect to characterize forest structure. These attributes were correlated with the stand density index and mean quadratic diameter to derive the various SDM categories. The following seven stand types have been defined and delineated using the Tongass Timber Inventory as the source for the analysis:

- SD4H: Volume class 4 on hydric soils
- SD4N: Volume class 4 on non-hydric soils, north aspect or flat
- SD4S: Volume class 4 on non-hydric soils, not north aspect or flat
- SD5H: Volume class 5 on hydric soils
- SD5N: Volume class 5 on non-hydric soils, north aspect or flat
- SD5S: Volume class 5 on non-hydric soils, not north aspect or flat
- SD67: Volume classes 6 and 7

These categories were used to develop a hierarchical mapping model for predicting tree sizes and densities on the Tongass National Forest. Figure 3.9-4 presents a description of each of the categories and illustrates the most probable forest type based on land form and forest condition. Figure 3.9-5 shows how the above SDM categories compare to the low-, medium-, and high-volume strata approach used for the 1997 Forest Plan. Based on their analysis, the authors suggest that the model is appropriate for use in forest or landscape planning on the Tongass (Caouette and DeGayner 2005). For example, the SDM is more useful in its ability to better define forest structure, both forest-wide and within stand, than the three-volume strata approach. Some components of the SDM have helped identify frequently used wildlife habitats in parts of the Tongass National Forest (Doerr et al. 2005, DeGayner et al. 2005). Other potential applications may include 1) broad-scale forest inventories; 2) stratification for reducing the amount or intensity of project-level field inventories; 3) developing forest structure value ranking systems for project-level analyses; 4) modeling diversity across landscapes or watersheds; and 5) setting and implementing conservation targets (DeGayner et al. 2005).

The disproportionate harvest of the larger POG types is an issue of concern relative to forest management on the Tongass. In the analysis that follows, we define the larger POG types in two ways. First, large-tree POG is defined as the SD67 POG type (Figure 3.9-4). This type represents the most productive of the POG types and typically contains the highest density of large trees. The second category is referred to as high-volume POG and is defined as the grouping of the three types that represent the highest volume stratum -- SD67, SD5N, and SD5s (Figures 3.9-4 and 3.9-5). This grouping represents the types with the largest trees on the Tongass.

Figure 3.9-4
Tree Size and Density Model used to Describe Forested Conditions across the Tongass National Forest

SD	*Land and Forest Condition* Most Probable Forest Type	*Tree Sizes and Densities* Most Probable Forest Type [1]	*Illustration* Most Probable Forest Type
4H	Low productive older forests associated with wet, poorly drained land types (e.g., muskegs, fens, rolling hills, broken mountain slopes, plateaus, glacial outwash zones). Canopy closure is variable. Trees are small, old, and defective. Stand volume is low.	Low densities **(SDI < 280)** of small-diameter trees **(QMD < 17 inches)**. Tree size distribution and spacing is variable and patchy. Tree diameters greater than 40 inches are generally not present.	4N	Low to moderately productive older upland forests. Canopy characteristics are variable and patchy, with moderate canopy closure and relatively coarse canopy texture. Stand volume is low to moderate.	Low densities **(SDI < 280)** of medium diameter trees **(17 < QMD < 21 inches)**. Tree size distribution and spacing is variable and patchy. Tree diameters greater than 40 inches are rare.	4S	Highly productive younger upland forests. Stand volume is moderate, but increasing rapidly. Crown competition is high. Canopy characteristics tend to be uniform, with high canopy closure and fine canopy texture.	High densities **(SDI > 280)** of medium-diameter trees **(17 < QMD < 21 inches)**. Tree size distribution and spacing tends to be more uniform. Tree diameters greater than 40 inches are rare.	5H	Moderately productive older forests associated with wet, poorly drained land types (see 4H above). Canopy closure, texture, and structure tend to be variable and patchy. Stand volume and annual growth is also variable and patchy.	Low densities **(SDI < 280)** of medium-diameter trees **(17 < QMD < 21 inches)**. Tree diameters greater than 40 inches are somewhat common, but not uniformly distributed throughout the stand.	5N	Moderately productive older upland forests. Stand volume is moderate to high. Canopy characteristics tend to be variable, with moderate canopy closure and coarse canopy texture.	Low densities **(SDI < 280)** of medium-to-large diameter trees **(17< QMD < 21 inches)**. Tree size distribution and spacing is variable and patchy. Tree diameters greater than 40 inches are common, but not uniformly distributed throughout the stand.	5S	Highly productive upland forests. Stand volume is high. Canopy characteristics tend to be uniform, with moderate to high canopy closures.	High densities **(SDI > 280)** of medium-diameter trees **(17 < QMD < 21 inches)**. Tree size distribution and spacing tends to be uniform. Tree diameters greater than 40 inches are somewhat common, but not uniformly distributed throughout the stand.	
67	Highly productive forests associated with riparian areas, alluvial fans, colluvial toe slopes, karst geology, and wind-protected uplands. Stand volume is high. Stand age can vary. Canopy closure is low to moderate and canopy texture is coarse.	Low densities **(SDI < 280)** of large-diameter trees **(QMD > 21 inches)**. Tree diameters greater than 40 inches are common and uniformly distributed throughout the stand.

Forest-Wide Distribution of Old-Growth Forest

The distribution and condition of the old-growth ecosystem across the Tongass can be examined by comparing the representation of various types of old growth by elevation and across the biogeographic provinces and ecological subsections, with regard to the original representation. As stated earlier, because other habitat types (e.g., non-forested and unproductive forest habitats) are fully represented across the Tongass and have not changed appreciably from original levels, the old-growth ecosystem is the primary focus for the analysis of biological diversity in this document.

Old Growth Distribution by Elevation

Elevation is considered one of the most significant landscape variables influencing old-growth forest habitat values. Three elevation zones are described in Table 3.9-4 and the acreages for these components are divided between the productive and unproductive old growth. The different elevation zones displayed (less than 800 feet, 800 to 1,500 feet, and greater than 1,500 feet) are important for many wildlife species during certain times of the year. For example, old-growth forest, particularly SD5S, SD5N, and SD67, provide suitable winter habitat for Sitka black-tailed deer through increased snow-intercept capabilities (see the *Wildlife* section in this chapter for species-specific discussion).

Table 3.9-4
Conifer Old-Growth Acres of the Tongass within Three Elevation Zones

Elevation Zone	Description	Productive Old Growth	Unproductive Old Growth	Total Old Growth
Less than 800 feet	All upland old growth below 800 feet in elevation	2,961,192	1,812,165	4,773,357
800 to 1,500 feet	All upland old growth between 800 and 1,500 feet in elevation	1,409,322	1,022,014	2,431,335
Greater than 1,500 feet	All upland old growth more than 1,500 feet in elevation	580,635	1,381,708	1,962,343
Total		**4,951,148**	**4,215,887**	**9,167,035**

POG forest (all SDM categories described in Figure 3.9-4 and outlined in Figure 3.9-5) found at lower elevations accounts for approximately 60 percent of the old-growth forest on the Forest. It should be noted that POG at lower elevations (at or below 800 feet in elevation) has been harvested disproportionately in some biogeographic provinces. Forest-wide, 60 percent of all POG is found at or below 800 feet in elevation (Table 3.9-4); however, approximately 80 percent of all old-growth forest harvested since 1954 occurred below this elevation zone.

Old Growth Distribution by Biogeographic Province and SDM Category

Sixteen of the 21 biogeographic provinces covering the Tongass currently have more than 100,000 acres of POG and 11 provinces have more than 200,000 acres. Three provinces – Admiralty, North Central Prince of Wales, and Revilla/Cleveland – include more than 500,000 acres of POG each. The current POG acreage in each SDM category is displayed by biogeographic province in Table 3.9-5. These acres by SDM category can serve as a baseline for the amounts of existing structural classes at the landscape level.

The same three provinces that contain more than 500,000 acres of POG, contain more than 200,000 acres of high-volume POG, with Admiralty containing over 300,000 acres. Seven provinces contain more than 100,000 acres of high-volume POG and 14 provinces contain more than 50,000 acres. Large-tree POG (SD67), however, is not as uniformly distributed. Forty percent of the large-tree POG on the Tongass is within two provinces: North Central Prince of Wales and Admiralty. Other provinces, in which large-tree POG comprises over 10 percent of the POG include Yakutat Forelands, Kuiu Island, Southern Outer Islands, and South Prince of Wales.

Forest-wide, the Tongass consists of 20 percent low-volume, 39 percent medium-volume, and 41 percent high-volume POG types. The province with the highest percentage of low-volume POG (SD4H) is the Kupreanof/Mitkof province, which has a high percentage of low-lying wetland areas. Portions of adjacent North Central Prince of Wales and Etolin Island and Vicinity provinces also contain large areas of the low-volume type.

Old Growth Distribution by Ecological Subsection and SDM Category

Examining the distribution of old growth by ecological subsection allows comparison at a smaller scale than the biogeographic province scale. The ecological subsections better define and describe habitats with similar overall vegetative patterns. Table 3.9-6 displays the POG forest acres within each of the 73 ecological subsections on the Tongass by SDM category. Ecological subsections vary dramatically in their ability to support POG, even within similar landforms, elevation,

and soil conditions. For example, the Gulf of Esquibel Till Lowlands and the Rowan Sediments vary from 32 percent to 72 percent covered by POG, respectively.

Sixty of the 73 ecological subsections currently have more than 20,000 acres of POG on National Forest System (NFS) land and 65 of the ecological subsections have more than 10,000 acres. The 13 subsections that currently have less than 20,000 acres, also had less than 20,000 acres of POG originally. Similarly, the 8 subsections with less than 10,000 acres had less than 10,000 acres originally. Fifteen ecological subsections currently have more than 100,000 acres of POG and only 2 subsections have less than 1,000 acres. The ecological sections containing the largest amounts of POG include the Inside Passage Fiordlands (1,208,000 acres), Kootznoowoo Fiordlands (653,000 acres), Baranof-Chichagof Fiordlands (573,000 acres), Kuiu-Prince of Wales Fiordlands (481,000 acres), Kupreanof Lowlands (388,000 acres), and the Coast Mountain Batholith Fiordlands (387,000 acres).

High-volume and large-tree POG occur throughout Southeast Alaska; however, their relative abundance varies across ecological subsections. High-volume POG represents more than 50 percent of all POG in 12 subsections. It occurs at the highest relative abundance in subsections within the Northern Gulf Forelands, Kuiu-Prince of Wales Fiordlands, and the Prince of Wales Mountains ecological sections. Similarly, large-tree POG makes up more than 20 percent of all POG in 9 subsections. It occurs in the highest relative abundance in the Northern Gulf Forelands, Kuiu-Prince of Wales Fiordlands, and the Prince of Wales Mountains ecological sections.

Past Old-Growth Harvest

Overview of Past Harvest on National Forest System Lands

Originally, 5.4 million acres of POG occupied the Tongass and 8 percent of this POG has been harvested. At least 10 percent harvest has occurred in six provinces—East Chichagof Island, East Baranof Island, Kupreanof/Mitkof Islands, Etolin Island, North Central Prince of Wales Island, and Southern Outer Islands (Table 3.9-7). With 26 percent POG harvest, North Central Prince of Wales has had

Table 3.9-7

[1] Original POG is defined in this EIS as the POG that existed, outside of towns, prior to all mapped timber harvest. About 300 acres were mapped as harvested in the 1700s and 1800s and about 16,000 acres are from the first half of the 1900s. The vast majority (about 438,000 acres) has occurred since 1950. To estimate original high volume and SD67 POG, an estimate was made of the percentage of past harvest in these categories using timber type mapping from the mid-1980s. Based on this analysis, prior harvest on NFS lands was estimated to have been 29% SD67 and 64% high volume (see Appendix B).
[2] High-volume POG contains the largest tree types (SD5S, SD5N, SD67).

the highest rate of past harvest. Ten provinces have had less than 5 percent harvest and six provinces have had 1 percent or less. Significant among these is Admiralty, which had nearly 600,000 acres of original POG and only about 1 percent harvest on NFS lands.

Approximately 454,724 acres of old growth have been harvested on the Tongass National Forest, with 96 percent (435,039 acres) having been harvested since 1954, when industrial-scale logging began. The two decades with the greatest amount of harvest were the 1960s and the 1970s; these two decades account for 50 percent of all Tongass old-growth harvest (Table 3.9-8).

Harvest practices and regulations on the Tongass have varied substantially over the years. The amount of harvest is categorized in Table 3.9-9 according to specific periods of relatively consistent land management.

Table 3.9-8
Past Harvest by Decade on the Tongass National Forest

Decade	Harvest Acres	Percent of All Harvest
2000-2006	15,507	3%
1990-1999	80,846	18%
1980-1989	87,946	19%
1970-1979	117,645	26%
1960-1969	109,544	24%
1950-1959	26,994	6%
1940-1949	6,456	1%
1930-1939	1,502	0%
1920-1929	5,064	1%
1910-1919	2,669	1%
<1910	550	0%
Total	**454,724**	**100%**

Table 3.9-9
Past Harvest Relative to Management Practices on the Tongass National Forest

Period	Harvest Acres	Period Description
1997-2006	29,218	Represents the current period under the 1997 Forest Plan (as amended); high level of resource protection
1991-1996	52,266	TTRA had passed and Forest Plan was under revision; proportional harvest for long-term contracts and stream buffers required
1979-1990	115,401	1979 Forest Plan was in effect, but prior to TTRA amendment
1954-1978	237,154	Prior to the first Forest Plan – initial period of industrial-scale logging; relatively few restrictions
1750-1953	20,685	Prior to the first Forest Plan and before industrial-scale logging began
Total	**454,724**	

In general, the more recent the harvest the more protections were in place. Approximately 57 percent of the harvest on the Tongass occurred prior to the protections adopted by the first Forest Plan in 1979. Another 25 percent was harvested after the first Forest Plan, but before the additional riparian protections and proportionality requirements of TTRA (see below). An additional 12 percent of the harvest took place after TTRA, but before the current Forest Plan was adopted, which implemented extensive harvest restrictions. Thus, only 6 percent of the old-growth harvest on the Tongass has taken place under the current Forest Plan, which offers the greatest protections.

Past harvest on the Tongass has disproportionately targeted the larger POG types. Early logging in particular, especially prior to the 1990s, extensively harvested the larger tree types. These types were not only the highest timber volume types, but they also often grew at lower elevations in the easiest areas to access (e.g., valley bottoms and lower slopes). When TTRA was passed, the harvest of the largest tree categories was limited as a proportion of total harvest. This applied only to the long-term contracts, which were in effect at the time and extended into the late 1990s.

In this discussion, larger POG types are defined by two categories: 1) large tree POG, also referred to as SD67, is the type with the largest average diameter tree diameter sizes and 2) high-volume POG, which includes the three largest types (SD67, SD5N, and SD5S), and represents the types with the highest average timber volume. Both of these categories are of high value for wildlife and aesthetics, but the large-tree POG is considered of highest value.

The proportion of harvest in these larger POG types was estimated based on timber type mapping conducted in the mid-1980s. As a result, we estimate that 31 percent of all harvest on NFS lands conducted prior to 1992 (when the proportionality requirement of TTRA began to be implemented) consisted of large-tree POG and 66 percent consisted of high-volume POG. From 1992 to the present, these percentages dropped to approximately 17 percent for large-tree POG and 52 percent for high-volume POG. The original composition of POG on the Tongass National Forest is estimated to have included 12 percent large-tree POG and 43 percent high-volume POG. Averaging all past harvest together, the weighted average harvest of large-tree and high-volume POG was 29 and 64 percent of the harvest. As a result of the cumulative disproportionate harvest on NFS lands over the years, the overall proportion of larger tree types on the Tongass have been reduced to 11 percent for large-tree POG and 41 percent for high-volume POG.

The composition of recent past harvest (under the current Forest Plan) by SDM category is summarized in the Tongass 2006 Annual Monitoring Report (USDA Forest Service 2007h). Of the 17,202 acres harvested during the period, 1998 through 2003, approximately 14 percent was from the large tree type (SD67) and 48 percent occurred in high-volume POG (SD5S, SD5N, and SD67), indicating that harvest has been slightly disproportionate during this period as well. However, this has been a period of relatively poor economics and only a small percentage of the total harvest allowed under the Forest Plan has been implemented.

Table 3.9-7 displays the original amount of POG and the percent remaining in different categories by biogeographic province. This table also provides an indication of the rate of past harvest for different types. For example, 87 percent of the original high-volume POG and 80 percent of the original large-tree POG are remaining Forest-wide. As noted above, the larger tree types were targeted for logging, especially at lower elevations. As a result, 84 percent of the original high-volume POG and 78 percent of the large-tree POG below 800 feet are remaining today.

Three provinces – East Baranof, Etolin, and North Central Prince of Wales – have had more than 20 percent of their high-volume POG harvested. Conversely, 13 provinces have had 10 percent or less of their high-volume POG harvested. Five provinces – East Baranof, West Baranof, Kupreanof/Mitkor, Etolin, North Central

Prince of Wales have had more than 30 percent of their large-tree POG harvested and 9 provinces have had 10 percent or less removed.

At low to intermediate elevations, the same limestone soils that produce karst topography and caves are very productive and produce some of the largest tree forests on the Tongass. As a result, POG forests on karst terrain have been harvested at a very high rate. Overall, 31 percent of all POG growing on karst soils of the Tongass has been harvested (95,000 acres harvested out of 303,000 original acres). Approximately 38 percent of the low elevation (less than 800 feet) POG growing on karst soils of the Tongass has been harvested (81,000 out of 216,000 acres). Over half of this harvest has occurred in the North Central Prince of Wales province where karst terrain is most well developed.

Overview of Past Harvest on Non-National Forest System Lands

Many of the non-NFS lands in Southeast Alaska are also available for timber harvest and much harvest has occurred on these lands, which cumulatively affects old-growth forest resources (see the *Timber* section in this chapter). The non-NFS landowners include the Alaska native corporations, the State of Alaska, and other private landowners and local governments within the Tongass boundary. Areas within Southeast Alaska, but outside the Forest boundary are managed by the National Park Service (Glacier Bay National Park), the Bureau of Land Management, the State of Alaska, and private landowners and local governments.

The major landowners that harvest timber on non-NFS lands within the Tongass boundary are the Alaska native corporations, including Sealaska, the regional corporation, and 12 village corporations. Together, the native corporations own and manage approximately 579,000 acres within the Tongass boundary (see Table 3.11-1 in the *Lands* section). In addition, the State of Alaska owns and manages 454,000 acres of lands within the Tongass boundary, and an additional 513,000 acres of lands north and west of Haines in and adjacent to the Haines State Forest. A portion of these state lands are managed for timber harvest. Other private landowners and local governments own and manage another 227,000 acres of lands within the Tongass boundary and a limited acreage outside the boundary; some of these acres are managed for timber.

Past old-growth harvest on non-NFS lands within the Tongass boundary consists of approximately 301,000 acres on native corporation lands (some of which is partial harvest), 35,000 acres on state lands, and 14,000 acres on other lands. Outside the Forest boundary, primarily in the Haines area, an additional 21,000 acres have been harvested. Thus, the total non-NFS harvest of old growth within the Tongass Forest boundary is approximately 351,000 acres and an estimated total of 371,000 acres have been harvested on non-NFS lands throughout Southeast Alaska.

Intensive harvest on non-NFS lands started later than on NFS lands, beginning in earnest in the late 1970s. High rates of harvest began in the early 1980s, peaking in the early 1990s, and decreasing to a lower level at present. The decades with the highest harvest were the 1980s and 1990s.

As a result of the timing of past harvest, a large majority (about 94 percent) of the second growth on non-NFS lands is less than 25 years old and is currently in the stand initiation stage. Only about 6 percent is currently in the early stages of the stem exclusion stage.

The Alaska Forest Resources and Practices Act (FRPA) (Alaska Statute 41.17) governs how timber harvesting, reforestation, and timber access can occur on state, private, and municipal land. The FRPA was originally adopted in 1978. Major revisions were adopted in 1990 to address riparian management on private land and other issues. Additional changes to the stream classification system and riparian management standards for coastal forests were adopted in 1999. Approximately 48 percent of the harvest on non-NFS lands in Southeast Alaska occurred prior to the major protective revisions to the FRPA in 1990. However, the majority of the harvest (52 percent) occurred after the FRPA revisions were adopted.

Disproportionate past harvest has occurred at a higher rate for large-tree POG and at approximately the same rate for high-volume POG on non-NFS lands compared with NFS lands. Overall, 37 percent of the non-NFS harvest acres consisted of large-tree POG and 62 percent consisted of high-volume POG. As a result of past harvest on non-NFS lands within the Forest boundary, the proportion of larger tree types has been reduced to 6 percent for large-tree POG and 37 percent for high-volume POG. Counting all non-NFS lands within Southeast Alaska, the percentages are 7 percent for large-tree POG and 56 percent for high-volume POG. The higher percentages for high-volume POG are because of the prevalence of these types and the low rate of harvest in the Glacier Bay and Chilkat River complex biogeographic provinces.

Cumulative Past Harvest

Overview

Cumulatively, of the 6.13 million acres of POG that originally existed on all lands within the Tongass Forest boundary (outside of that occupied by towns), approximately 805,000 acres or 13 percent has been harvested. When considering all of Southeast Alaska, including Glacier Bay National Park and the lands around Haines and Skagway, approximately 826,000 acres, or 13 percent, have been harvested out of 6.5 million acres of original POG. Approximately 92 percent of the original POG is present on the Tongass and 66 percent is estimated to remain on non-NFS lands. The percent of total POG remaining for all of Southeast Alaska is estimated to be 87 percent.

Timber harvest has occurred in a spatially clumped fashion within Southeast Alaska, with activity concentrated on islands, such as Prince of Wales, northeast Chichagof, northern Kuiu, and Zarembo. Very little activity has occurred on some other islands and much of the mainland (e.g., within the 19 designated Wilderness Areas and National Monuments and 12 legislated LUD II areas). Table 3.9-10 displays the land area, acreage of remaining POG and POG harvested, and percentage of POG remaining by land category for all lands in Southeast Alaska by biogeographic province. The percentage of the original POG forest no longer in an old-growth condition can serve as a general indicator of the potential effect on several biodiversity aspects, including structural (within-stand) diversity, connectivity (unfragmented, continuous old-growth blocks), and age and species composition (including understory species).

Some harvest has occurred in 20 of the 23 biogeographic provinces in Southeast Alaska; however, 13 provinces have over 90 percent of their original POG remaining (Table 3.9-10). Over 30,000 acres have been harvested in 6 biogeographic provinces (Table 3.9-10); the harvest in these 6 provinces accounts for about 75 percent of all harvest in Southeast Alaska. Only 2 provinces, North Central Prince of Wales and Dall Island and Vicinity, have had 20 percent or more of their original POG harvested.

Disproportionate Past Harvest

Across the Tongass and Southeast Alaska in general, timber harvest has been concentrated in the larger tree types and the higher timber volume classes. While approximately 87 percent of all POG remains across Southeast Alaska, about 82 percent of high-volume POG remains unharvested, and about 68 percent of large-tree POG remains. To a lesser extent, timber harvest has also been concentrated at the lower elevations (e.g., approximately 84 percent of the high-volume, low-elevation old growth remains unharvested on NFS lands compared with 87 percent of high-volume POG on NFS lands in general) (Table 3.9-7).

Large-tree stands found in alluvial river bottoms and karst areas were the target of early clearcut logging throughout Southeast Alaska (especially in the 1950s through the 1970s); some clearcuts were extensive and in many cases trees were harvested to the stream banks. With growing concerns over fisheries protection and proportionality, buffer restrictions were instituted in the 1990s.

As timber harvest moved away from streams and further inland, large-tree karst forests began to receive more logging pressure than did the riparian and alluvial fan forests due to their excellent drainage and the ease of road-building on these low, rolling landscapes (Albert and Schoen 2007, Chapter 2).

Most harvested POG was high-volume POG and a high proportion of this harvest was the largest tree category (SD67). Approximately 10 percent of the remaining POG in Southeast Alaska is mapped as the largest tree category (SD67); 42 percent of the remaining POG is mapped as high volume. The greatest concentrations of POG in the largest tree categories are in the North Central Prince of Wales and the Admiralty Island Biogeographic Provinces. These two biogeographic provinces account for 40 percent of the remaining large-tree POG inside the Forest boundary and 38 percent of the remaining large-tree POG in Southeast Alaska (Tables 3.9-7 and 3.9-10). These values serve as baselines for comparison with potential changes under the alternatives considered in this analysis.

Albert and Schoen (2007) estimate that, although approximately 10 percent of all POG is represented by large-tree forests, it has been harvested at a rate of nearly three times its availability on the landscape. Furthermore, harvest of these large-tree stands has primarily occurred at low elevations, particularly within valley floor (flood plain) areas and on karst lands. Albert and Schoen (2007) estimate that low elevation karstland forests make up only 2.7 percent of the region's POG, but these types have also been the focus of timber harvest in Southeast Alaska, accounting for approximately 15 percent of all timber harvest in Southeast Alaska (Chapter 2, Table 4).

Harvest of POG growing on karst terrain may be the most disproportionate example of the types of past harvest. Karst mapping covers 458,000 acres of the Tongass, 303,000 acres (66 percent) of which was originally covered by POG. Although limited amounts of karst POG occur in almost all provinces of Southeast Alaska, the majority is found in five provinces: North Central Prince of Wales, Southern Outer Islands, Dall Island and Vicinity, East Chichagof, and Admiralty Island.

Today, 208,000 acres (69 percent) of the original POG on karst terrain remains. Therefore, 31 percent of the original POG on NFS karst terrain has been harvested, compared with 8 percent of POG in general. Karst POG at low elevations were targeted by early harvest activity at an even higher rate. Of the 216,000 acres of karst POG originally found at low elevations (less than 800 feet) on NFS lands, 81,000 acres or 38 percent have been harvested.

[1] Includes Annette Island and all of the Ice Fields province, although they are not entirely within the Forest boundary.

Although only 26,000 acres of mapped karst POG originally occurred on non-NFS lands, harvest rates are higher if non-NFS lands are considered as well. Assuming that 50 percent of all non-NFS karst POG and 75 percent of all non-NFS low elevation karst POG have been harvested, the overall harvest rate for karst POG in Southeast Alaska was estimated at 33 percent overall, and 41 percent for low elevation karst.

Current Conditions by Biogeographic Province

This section summarizes the affected environment in each biogeographic province, with respect to past harvest and other past developments on NFS and non-NFS lands. The primary sources for this information include the Tongass GIS layers, GIS layers provided by the State of Alaska, GIS layers provided by Sealaska Corporation, interpretation of aerial photographs and orthophotography to create new GIS layers, GIS layers developed by The Nature Conservancy based on satellite imagery (Albert and Schoen 2007), and the State's FRPA detailed plan of operation database of harvest activities on non-NFS lands. A tabular summary of past harvest information is presented as a catalogue of past harvest in Appendix E.

A description of the climate, topography, vegetation, and other factors related to biodiversity is provided for the 23 biogeographic provinces in Southeast Alaska in Table 3.9-1. In addition, a description of the natural history for 22 biogeographic provinces (some of these provinces follow different boundaries) in Southeast Alaska is presented by Carstensen et al. (2007). Some of the key relevant information from both of these sources is also summarized here.

In addition, these sections summarize the effects of past harvest on the biodiversity and old-growth habitats of Southeast Alaska. The effects of past harvest are differentially discussed for NFS and non-NFS lands, as well as cumulatively. A similar analysis of the current condition of old-growth integrity and biodiversity within the biogeographic provinces of Southeast Alaska is presented by Carstensen et al. (2007).

<u>Yakutat Forelands</u>

The Yakutat Forelands biogeographic province is a very young and nearly flat landscape at the northern end of Southeast Alaska that supports a complex mosaic of forest and wetlands. Approximately 65 percent of the province is in congressionally protected land designations (mostly in the Yakutat Forelands LUD II and Glacier Bay National Park). Private and State of Alaska lands comprise about 5 percent of the province and consist primarily of Yak-Tat Kwaan Village Corporation lands (4 percent of the province). State of Alaska lands also comprise a significant percentage (1 percent of the province).

A relatively low percentage of NFS POG has been harvested (about 4,000 acres). As a result, approximately 93 percent of the original POG on NFS land remains today. The native corporation and state lands in the province (mostly near Yakutat), have experienced relatively high harvest (about 14,000 acres); however, essentially no harvest has occurred in Glacier Bay National Park within the province. As a result, about 75 percent of the original POG remains on non-NFS lands. Most of the harvest took place in the mid-1980s or earlier, so the young growth that resulted is primarily at the end of the stand initiation stage or the beginning of the stem exclusion stage (Appendix E). Overall, 84 percent of the original POG on all lands within the province remains today. Harvest of larger tree types has occurred at a rate slightly higher than the overall rate and it is estimated that the percentage of high-volume and large-tree POG remaining today is 81 percent for both categories.

One very large block of large-tree POG exists in the upper Situk River and adjacent small watersheds, near the northeastern edge of the province. As a result of this large block and other patches, 51 percent of the existing POG in the province is mapped as high volume and 29 percent is mapped as large-tree POG. These percentages are among the highest of the provinces in Southeast Alaska, although the province includes only 89,000 acres of existing POG. However, this province is prone to extensive windthrow events, and the extensive large-tree POG in this area is susceptible to blowdown as well as future harvesting.

Past harvest has not significantly affected the biodiversity of the province or the integrity of the old-growth ecosystem, except on native corporation lands in a relatively confined area east of Yakutat where extensive harvest has taken place. Although POG has been locally harvested intensively, the overharvest of large-tree or high-volume POG has not been a significant factor in this province. Past blowdown events have also reduced the extent of old growth within the province. However, because the landscape of the Yakutat Forelands is so geologically young, this natural reduction of old growth by wind is compensated somewhat, by the natural succession of large acreages of younger forest that have colonized fresh substrates.

Yakutat Uplands

This rugged and mountainous province includes extensive active glaciers, fiords, and mountains rising from sea level to more than 10,000 feet. Approximately 38 percent of the province is in congressionally protected land designations (primarily the Russell Fiord Wilderness). Aside from a few acres of private lands (less than 0.1 percent), the province is virtually 100 percent within the Tongass National Forest.

Slightly over 1,000 of the 25,000 original acres of POG in the province have been harvested; therefore, 94 percent of the original POG remains today. Harvest of larger tree types has occurred at a higher rate so it is estimated that the percentage of high-volume and large-tree POG remaining today is 92 and 83 percent, respectively.

High-volume POG makes up almost half of the POG in the province (46 percent). However, large-tree POG comprises only 9 percent because of the lack of highly productive sites. The province contains only about 23,000 acres of existing POG. Portions of the province are prone to extensive windthrow events, as is the case for the Yakutat Forelands province.

Because past harvest has been so low in this province, little effect on the biodiversity or old-growth ecosystem integrity of the province has occurred. As is the case for the Yakutat Forelands province, wind may play the role of diminishing existing old growth, while primary succession of natural young-growth forests will contribute to the extent of POG over time.

East Chichagof Island

This rugged province is characterized by steep, U-shaped valleys and rounded mountains and is deeply dissected into three peninsulas. Karst terrain occupies high elevations and steep sideslopes, mostly above the POG, but the U-shaped valleys contain a substantial amount of valley floor POG, including large-tree types. Approximately 31 percent of the province is in congressionally protected land designations (25 percent in four LUD II areas and 6 percent in the West Chichagof-Yakobi Wilderness). Non-NFS lands comprise about 8 percent of the province, and consist primarily of Sealaska lands (5 percent of the province) and Huna Totem

Village Corporation lands (2 percent of the province). It includes the town of Hoonah and several smaller settlements including Tenakee Springs and Pelican.

Approximately 10 percent of the original POG on NFS lands has been harvested (about 44,000 acres). Most of this harvest took place in the 1970s, 1980s, and 1990s (Appendix E). On native corporation lands and other non-NFS lands in the province, approximately 38,000 additional acres or 52 percent have been harvested, primarily in the past 25 years. As a result, about 90 percent of the original POG on NFS lands, about 48 percent of the original POG on non-NFS lands, and about 84 percent of the original POG on all lands remains today. The vast majority of all harvest has taken place within the last 25 years and, therefore, the resulting young growth is in the stand initiation stage of succession. Harvest of the larger tree types (especially large-tree POG) occurred at a high rate relative to other POG types in this province, and it is estimated that 76 percent of the high-volume types and 58 percent of the large-tree types remain today.

Most high-volume and large-tree POG occurred along the shoreline and within valley bottoms in the province, and this POG was targeted by past harvest. Although only about 16 percent of all POG has been harvested in the province, approximately 42 percent of all large-tree POG and 24 percent of all high-volume POG has been harvested. This province also originally contained about 46,000 acres of POG on karst terrain. About 17 percent of this karst POG has been harvested.

Past harvest has had a substantial effect on old-growth ecosystems in some watersheds of this province. This has occurred in many of the watersheds on NFS lands of northeast and southeast Chichagof, and on native corporation lands to the south, southeast, and west of Hoonah. As noted above, overharvest of high-volume POG, and especially large-tree POG, has occurred and floodplain/valley bottom large-tree POG was targeted in the past in many of these watersheds. Because of the rugged topography of this province, the largest tree forests and the easiest access for logging were concentrated in these valley bottom areas. The rate of disproportionate harvest on NFS lands was substantially reduced with the passage of the Tongass Timber Reform Act in 1990 (which had a proportionality requirement for high vs. low volume Forest-wide) and with the adoption of the 1997 Forest Plan, which incorporates large portions of the floodplain areas on Chichagof Island within riparian buffers; however, most past harvest was conducted prior to the 1990s (Appendix E).

One area of particular concern is the narrow neck of land that connects northeast Chichagof to the main body of the island. This “pinch-point” or “bottleneck” may constrain wildlife movements and genetic interchange for other plants and animals because of the relatively narrow corridors of habitat between saltwater areas. This area has experienced some past harvest and could be significantly affected if substantial future harvest in this area were to occur. A second area of concern is the pinch-point connecting Lisianski Inlet with the North Arm of Peril Strait in the western portion of the province. However, this area lies completely within congressionally protected land designations. See the *Wildlife* section for a description of pinch-points and an analysis of the effects of additional development in these areas on wildlife movements.

<u>West Chichagof Island</u>

This province has a very wet climate and is exposed to outer coastal storms. It has a highly irregular shoreline with hundreds of small islands. Topography is gentler than the mountains of Baranof Island. Approximately 87 percent of the province is within congressionally protected land designations, mostly within the West

Chichagof – Yakobi Wilderness. Non-NFS lands comprise less than 0.5 percent of the province.

As a result of the high proportion of congressionally protected areas and the relatively low productivity of the province, no known harvest has taken place, either on NFS lands or on non-NFS lands. Therefore, the original percentage of high-volume and large-tree POG remain today. Approximately 24 percent of the POG in the province is high volume and 3 percent is large-tree POG. The province includes about 72,000 total acres of POG.

East Baranof Island

The East Baranof Island province is rugged and steep to saltwater, with relatively few flat lands. It includes among the highest and most rugged topography found on the islands of Southeast Alaska. Approximately 23 percent of its land area lies within the South Baranof Wilderness. Less than 1 percent of the province is comprised of non-NFS lands (the majority of which is state-owned).

Approximately 13 percent of the original POG on all lands has been harvested (about 14,000 acres), resulting in 87 percent of the original POG remaining. The majority of the harvest in this province was conducted in the 1960s (Appendix E), when relatively few restrictions on harvesting were in place. About 77 percent of the original high-volume POG and about 33 percent of the original large-tree POG remains today, indicating a high disproportionate harvest, particularly of large-tree POG.

The remaining large-tree POG is relatively scattered in small patches, often occurring in valley bottoms. However, high-volume POG occurs in many areas and along shorelines and within river valleys.

As is the case for East Chichagof, past harvest in the East Baranof Island province has had a substantial effect on old-growth ecosystems of several watersheds in the northern portion of the province. As noted for East Chichagof, overharvest of high-volume POG, and especially large-tree POG, occurred in floodplain/valley bottom areas, which were targeted because of the presence of large trees and the rugged topography elsewhere. Also as noted for East Chichagof, the rate of disproportionate harvest on NFS lands was substantially reduced with the passage of the Tongass Timber Reform Act in 1990, and with the adoption of the 1997 Forest Plan; however, most past harvest was conducted prior to the 1990s (Appendix E).

West Baranof Island

This province is similar to the West Chichagof Island Province with the exception of southern Baranof, which has exceptionally high precipitation. Baranof Island is the most rugged of all the islands in Southeast Alaska. Approximately 31 percent of the province is protected within the South Baranof Wilderness or the Enacted Municipal Watershed of Sitka. Non-NFS lands comprise about 4 percent of the province and consist of lands owned by the city and borough of Sitka, the State of Alaska, Shee Atika Village Corporation, and a variety of other private owners.

Approximately 7 percent of the original POG on NFS lands has been harvested (about 17,000 acres). On the State of Alaska and other non-NFS lands, 16 percent (2,000 acres) has been harvested. Overall, this results in 92 percent of the original POG on all lands remaining today. The vast majority of these acres were harvested 30 to 40 years ago and they are now in the stem exclusion stage of succession (Appendix E). High-volume POG was harvested at a rate higher than the overall harvest rate; 82 percent of all high-volume POG remains. Large-tree POG has been harvested at a much higher rate; an estimated 44 percent of all large-tree POG remains today.

Most remaining high-volume and large-tree POG is distributed along the shoreline and in river valleys. On all land ownerships combined, 25 percent of all POG is high volume, but only 2 percent is large-tree POG.

Although the overall rate of past harvest within the province is relatively low, the rate for the northern portion of the province is relatively high and the effects of past harvest on some watersheds in this area has also been relatively high. As noted for East Chichagof and East Baranof, overharvest of large-tree POG has occurred in floodplain/valley bottom areas, which were targeted because of the presence of large trees and the rugged topography elsewhere. As a result, less than half of the original large-tree POG in the province remains today.

Admiralty Island

The Admiralty Island Province has relatively gentle topography and moderate rainfall. Forest productivity is high. Approximately 90 percent of the province is protected within the Admiralty National Monument (Kootznoowoo Wilderness). Non-NFS lands in the province represent 4 percent of the land area and primarily consist of Shee Atika Village Corporation lands near Cube Cove, as well as lesser amounts of Sealaska Regional Corporation and State of Alaska lands and other ownerships. The village of Angoon occurs on the west side of the island and the Greens Creek mine at the north end of the island. The Greens Creek mine is the largest operating mine on the Tongass; however, it only occupies about 320 acres for facility development (see *Minerals* section).

Admiralty Island province ranks second in POG acreage relative to all other provinces in Southeast Alaska (598,000 acres). Before commercial timber harvest was initiated, it ranked third in POG acreage. Although 99 percent of the original POG on NFS lands remains today, about 72 percent (20,000 acres) of the POG on non-NFS lands has been harvested and only 28 percent is remaining. Because of the dominance of NFS lands in the province, 95 percent of the original POG remains on all lands combined. High-volume and large-tree POG have been harvested at a rate slightly higher than the overall POG harvest rate; 94 percent of all high-volume POG and 91 percent of all large-tree POG remain today.

High-volume and large-tree POG are abundant throughout the province. On all lands combined, approximately 51 percent of POG is high volume and 17 percent consists of large-tree POG. This province also originally contained about 38,000 acres of POG on karst terrain. Only about 3 percent of this karst POG has been harvested.

Although most of the province has experienced little to no past harvest, the area on native corporation lands near Cube Cove in the northwest portion of the province has been extensively harvested. Because the majority of all POG in three major adjacent drainages and adjacent areas near Cube Cove has been harvested, effects on the biodiversity and old-growth integrity in this local area have been substantial. However, the vast majority of Admiralty Island remains intact and, as a result of the abundance of POG in this province, including high-volume and large-tree POG, it represents a massive reserve and reservoir for biological diversity in Southeast Alaska.

Lynn Canal

The Lynn Canal province is characterized by rugged and glaciated topography and relatively low precipitation. The southern portion of the Chilkat Peninsula is more similar to the East Chichagof Island Province than to the rest of the province. Approximately 22 percent of the province is included within congressionally protected land designations (15 percent wilderness and 6 percent LUD II). Non-

NFS lands comprise about 4 percent of the province; the State of Alaska manages the majority of this land. The cities of Juneau and Douglas occur on the east side of Lynn Canal within the province.

Approximately 169,000 acres of POG currently exists in the province and 6,000 acres have been harvested. As a result, approximately 97 percent of the original POG remains today. High-volume POG and large-tree POG have both been harvested at a higher rate than other POG; 95 percent of high-volume POG remains, but only 88 percent of large-tree POG remains today.

The overall effects of past harvest on the biodiversity and old-growth ecosystem integrity within the province have been relatively low, because of the relatively low harvest rates. However, localized pockets of high harvest have occurred on the west side of Lynn Canal.

Northern Coast Range

The Northern Coast Range covers the rugged and glaciated coastal mountains of the northern mainland. It is characterized by deep fiords, tidewater glaciers, and active glacial rivers, including the Taku and Whiting Rivers, which extend into Canada. It also includes some less rugged topography on Douglas Island, Cape Fanshaw, and other locations. Approximately 23 percent of the province is in a congressionally protected land designation (wilderness) and an additional 1 percent is in a research natural area. Approximately 10 percent of the province (103,000 acres) is non-NFS lands, with the largest landowners being Goldbelt Village Corporation (35,000 acres), the State of Alaska (19,000 acres), and the city and borough of Juneau (19,000 acres)

Approximately 356,000 acres of POG currently exists in the province and about 21,000 acres have been harvested. Overall, 94 percent of the POG, 77 percent of the large-tree POG, and 92 percent of the high-volume POG remains today. However, almost all of the past harvest in the province is from non-NFS lands owned by Goldbelt in the vicinity of Hobart Bay. As a result, 65 percent of all POG on non-NFS lands remains and only 33 percent and 57 percent of the large-tree and high-volume POG types remains today on these lands, respectively.

On all lands combined, 7 percent of all POG is large-tree POG and 42 percent is high volume. Remaining larger tree types are well distributed at lower elevations throughout the province, except in the vicinity of Hobart Bay.

Although only about 6 percent of the original POG in the province has been harvested, as noted above, it is concentrated in the vicinity of Hobart Bay. Approximately two-thirds of the POG and a higher percentage of the larger tree types have been removed in this area on non-NFS lands. Thus, the effects of past harvest in the watersheds of this area have been relatively high.

Kupreanof/Mitkof Island

This province covers Kupreanof and Mitkof Islands in the center of Southeast Alaska and represents the province with the greatest extent of low-lying, muskeg wetlands. Because of the less rugged relief in the province, it is not as topographically fragmented as most other provinces; however, natural fragmentation of old growth does occur, due to the extensive wetlands. Approximately 6 percent of the lands of the Kupreanof/Mitkof Island province are in congressionally protected land designations; this is one of the lowest percentages in Southeast Alaska. Another 1 percent is protected in municipal watershed status. Non-NFS lands cover 90,000 acres, or 11 percent of the province. The State of Alaska is the largest individual landowner (31,000 acres), followed by Sealaska Regional Corporation (27,000 acres) and Kake Village Corporation (24,000 acres). Petersburg, Kake, and a few smaller settlements occur within this province.

POG currently exists on 335,000 acres and there has been about 71,000 acres of harvest in the province. Overall, 83 percent of the original POG remains today; however, 90 percent of NFS POG and 46 percent of non-NFS POG remains. Disproportionate harvest of larger tree types has occurred on NFS lands; about 65 percent of the original large-tree POG and 81 percent of the original high-volume POG remains. Disproportionate harvest has occurred even more intensively on non-NFS lands; only 8 percent of the original large-tree POG and 28 percent of the original high-volume POG remains. As a result of past disproportionate harvest and the relatively low original proportion of larger tree types in this province, large-tree POG and high-volume POG make up only about 6 percent and 32 percent of existing POG, respectively.

Harvest has occurred in many areas throughout the province and the remaining POG is also distributed throughout. However, the northwest corner of Kupreanof Island, near Kake, has been the most extensively harvested. The heavy POG harvest, especially of the larger tree types, has likely negatively affected biodiversity in this area.

One area of particular concern in this province is the narrow area between Lindenburg Peninsula and the remainder of Kupreanof Island. This pinch-point may constrain wildlife movements and genetic interchange for other plants and animals because of the relatively narrow corridors of habitat between saltwater areas. These areas have experienced some past harvest and could be significantly affected if substantial future harvest were to occur in this area. However, this area is largely protected by the Petersburg Creek-Duncan Salt Chuck Wilderness. See the *Wildlife* section for a description of pinch-points and an analysis of the effects of additional development in these areas on wildlife movements.

<u>Kuiu Island</u>

The Kuiu Island province has gentle topography relative to adjacent Baranof Island or the mainland. Kuiu Island is deeply dissected, creating several prominent peninsulas and obstacles to wildlife movements. Approximately 27 percent of the province is in congressionally protected land designations (mostly wilderness). The province is 99 percent NFS lands; only a few thousand acres are owned by others.

Approximately 296,000 acres of POG, containing about 12 percent large-tree POG and 53 percent high-volume POG, remains in the province. This compares with an estimated 325,000 original acres of POG, containing about 14 percent large-tree POG and 54 percent high-volume POG, indicating a slightly higher rate of past harvest of the larger tree types for all lands combined. Overall, 91 percent of all POG, 90 percent of high-volume POG, and 82 percent of large-tree POG remains today.

Most past harvest occurred in this province during the 1970s and 1980s (Appendix E). Although logging has occurred in many portions of the province, the southern two-thirds of the province has experienced relatively low rates of harvest. In contrast, the northern one-third of the island has undergone fairly extensive harvest, which began relatively intensively in the late 1960s. Because much of this logging occurred in the early years, prior to the implementation of many Forest Plan protections, some fairly extensive tracts are now in the stem exclusion stage of succession. Some of these watersheds with extensive early harvest have experienced relatively high old-growth fragmentation and effects on biodiversity.

One area of particular concern in this province is the narrow neck of land between the Bay of Pillars and Port Camden and the portage between Port Camden and

Threemile Arm, which connect the northern and eastern parts of the island to the rest of Kuiu Island. These pinch-points may constrain wildlife movements and genetic interchange for other plants and animals because of the relatively narrow corridors of habitat between saltwater areas. These areas have experienced some past harvest and could be significantly affected by substantial future harvest, if it were to occur. See the *Wildlife* section for a description of pinch-points and an analysis of the effects of additional development in these areas on wildlife movements.

Central Coast Range

The Central Coast Range covers the rugged and glaciated coastal mountains of the central mainland. It is similar to the Northern Coast Range, although it is less precipitous and warmer. The Stikine River system traverses the center of this province and has a major continental influence on it. Approximately 37 percent of the province is protected within the large Stikine-LeConte Wilderness. NFS lands comprise 97 percent of the province, State of Alaska lands cover 2 percent, and there are no other landowners with more than a few hundred acres.

POG currently exists on 251,000 acres and there has been about 8,000 acres of past harvest. Overall, 97 percent of the original POG remains today. Disproportionate harvest of larger tree types has occurred to some degree; about 95 percent of high-volume POG and 89 percent of large-tree POG remains today. High-volume and large-tree POG represent about 42 percent and 8 percent of the remaining POG, respectively.

The majority of the watersheds in the province have experienced no past harvest to very minor effects from past timber harvest. Exceptions are watersheds in the Thomas Bay area and the Bradfield River drainage. Relatively high rates of past harvest, including large-tree harvest, have had some negative effects on old-growth integrity and biodiversity in these watersheds.

Etolin Island and Vicinity

The Etolin Island and Vicinity province includes Etolin, Wrangell, Zarembo, and smaller islands. It is similar to the Kupreanof/Mitkof province and is subject to continental influence from the mainland and the Stikine River. Congressionally protected land designations (South Etolin Wilderness) cover 16 percent of the province and 95 percent of the province is under national forest management. The State of Alaska manages almost 5 percent of the province and the city of Wrangell owns almost 1 percent.

Approximately 232,000 acres of POG, containing about 35 percent high-volume POG and 6 percent large-tree POG, remains in the province. This compares with an estimated 273,000 original acres of POG, containing 39 percent high-volume POG and 9 percent large-tree POG, indicating a higher rate of past harvest of the larger tree types. Overall, 85 percent of all POG, 76 percent of high-volume POG, and 51 percent of large-tree POG remains today. Although disproportionate harvest has occurred on all ownerships, non-NFS lands have had the highest rate of disproportionate harvest; the 4,000 acres of past harvest on non-NFS lands included 39 percent of the high-volume and 80 percent of the large-tee POG.

Most harvest in this province occurred in the 1970s and 1980s (Appendix E). Harvest has occurred throughout the province, but especially on northern Etolin and Zarembo Islands, central Wrangell Island, and many of the smaller islands in the province. Watersheds containing the highest rates of past harvest include those on northwest Zarembo Island and the majority of Vank and Sokolof Islands. Past harvest in these areas and on some state lands has had negative effects on local biodiversity.

North Central Prince of Wales Island

The North Central Prince of Wales Island province covers the northern and central portions of Prince of Wales Island and some adjacent islands. It has relatively gentle topography and extensive areas of karst and limestone soils. Approximately 8 percent of the province is protected in congressional land designations (wilderness and LUD II) and approximately 79 percent of the province is under national forest management. Other major landowners include: Sealaska Regional Corporation (11 percent), State of Alaska (5 percent), Kavilco Village Corporation (2 percent), Klawock-Heenya Village Corporation (2 percent); Shan-Seet Village Corporation (1 percent); and Haida Village Corporation (1 percent). A number of small towns and settlements occur within the province including Craig, Klawock, Thorne Bay, Hydaburg, Coffman Cove, Hollis, and others.

The North Central Prince of Wales Island province originally contained more POG than any other province in Southeast Alaska and, after half a century of commercial timber harvest, it still does. The province currently contains 599,000 acres of POG; about 320,000 acres or 35 percent of the original POG have been harvested. Approximately 74 percent of the original POG remains on NFS lands and 38 percent remains on non-NFS lands. For high-volume POG, an estimated 66 percent remains on NFS lands and 24 percent remains on non-NFS lands. Similarly, for large-tree POG, an estimated 69 percent remains on NFS lands and only 12 percent remains on non-NFS lands.

Almost all of the past harvest on NFS lands took place in the 1960s through the 1990s, with the majority occurring in the 1960s and 1970s. On non-NFS lands, most of the harvest took place in the 1980s and 1990s, with substantial acreage harvested in the current decade as well (Appendix E). Therefore, a mixture of age groups occurs and the young growth in this province is split between the stand initiation and stem exclusion stages of plant succession.

This province originally contained about 152,000 acres of karst POG, or almost half of the karst POG within the Forest boundary in Southeast Alaska. About 72,000 acres, or 47 percent, has been harvested. This percentage climbs to about 52 percent if only karst POG at low elevations (less than 800 feet) is considered.

On NFS lands, 44 percent of the existing POG is high volume and 23 percent is large tree POG. On non-NFS lands, 31 percent of existing POG is high volume and 8 percent is large tree POG. Overall, 42 percent of the remaining POG on all lands is high volume and 20 percent is large tree POG. Because of its abundance, POG is still well distributed within the province; however, there are many areas of past intensive harvest where negative effects on biodiversity have likely occurred. These areas include parts of northern Prince of Wales Island; the Staney Creek, Thorne Bay, Big Salt, Craig/Klawock, and Hollis areas of central Prince of Wales Island; and much of Kosciusko and Tuxekan Islands.

One area of particular concern in this province is the Neck Lake area, which is a relatively narrow piece of land between Whale Passage and El Capitan Passage connecting the extreme northern Prince of Wales to the remainder of the island. This pinch-point could constrain wildlife movements and genetic interchange for other plants and animals because of the relatively narrow corridors of habitat between saltwater areas. In addition, this area has experienced relatively high past harvest and could be significantly affected by substantial future harvest, if it were to occur. See the *Wildlife* section for a description of pinch-points and an analysis of the effects of additional development in these areas on wildlife movements.

In addition, Sulzer Portage, a relatively narrow neck of land on Prince of Wales Island connecting West Arm Cholmondeley Sound and Portage Bay at the head of Hetta Inlet. It joins the North Central Prince of Wales and the South Prince of Wales Island provinces and has had considerable past timber harvest. Due to recent land selections, the immediate portage is entirely on non-NFS lands. Substantial future harvest, if it were to occur, could substantially affect ecological connectivity. See the *Wildlife* section for a description of pinch-points and an analysis of the effects of additional development in these areas on wildlife movements.

Revilla Island/Cleveland Peninsula

This province includes Revillagedo (Revilla), Gravina, Annette, Duke, and smaller islands, as well as the Cleveland Peninsula portion of the mainland. Approximately 23 percent of the province is in congressionally protected land designations (wilderness national monument and LUD II) and an additional 1 percent is in a municipal watershed status. About 85 percent of the province is under national forest management. The Annette Island Indian Reservation is the second largest ownership with 7 percent of the province, the State of Alaska is the third largest landowner with 5 percent, followed by Cape Fox Village Corporation at 2 percent, and Sealaska Regional Corporation at 1 percent. The cities of Ketchikan, Saxman, and Metlakatla occur within the province.

This province has the third largest number of acres of POG among all Southeast Alaska provinces. Approximately 573,000 acres of POG currently exist in the province, and 70,000 acres have been harvested. The remaining POG consists of 41 percent high-volume POG and 6 percent large-tree POG. Originally, 44 percent of the POG was high volume and 9 percent was large-tree POG, indicating a higher rate of past harvest of larger tree types. Overall, 89 percent of all POG, 84 percent of high-volume POG, and 59 percent of large-tree POG remains today. Although disproportionate harvest occurred on all ownerships, non-NFS lands had the highest rate of disproportionate harvest: the 25,000 acres of past harvest on non-NFS lands included 38 percent of the high-volume and 91 percent of the large-tree POG.

Harvest on NFS lands in this province has been relatively evenly distributed over time beginning in the 1950s, with the highest decadal harvest in the 1990s (Appendix E). Harvest on non-NFS lands has generally occurred in the more recent decades. Relatively high concentrations of past harvest have occurred at a number of areas along Behm Canal, George Inlet, Carroll Inlet, and near Ketchikan on Revilla Island and on northern Annette Island. In many of these areas, biodiversity has been affected due to the intensity of past harvest and the higher reductions in larger tree POG types.

Southern Outer Islands

The Southern Outer Islands is a small, isolated province subject to strong oceanic influences. Topography is low-lying and gentle and the islands are relatively rich in endemic vertebrate species. Almost half (49 percent) of the province is in congressionally protected land designations (wilderness and LUD II) and 94 percent of the province consists of NFS lands. Other major landowners include: Shaan-Seet Village Corporation (3 percent); State of Alaska (2 percent); and Sealaska Regional Corporation (1 percent).

The province contains a high proportion of POG relative to its size. It contains about 118,000 acres of existing POG and 21,000 acres of harvest have occurred; thus, the remaining POG represents 85 percent of the original POG acreage. The majority of the islands in the province have had little or no past harvest; harvest has been concentrated on Heceta Island, and to a lesser extent on San Juan Batista and Suemez Islands. Most NFS harvest was conducted in the 1960s through the 1980s

(Appendix C). Heceta Island is mostly covered with karst terrain and limestone soils and originally contained fairly extensive stands of large-tree karst POG; most of these stands have been cut. Today, about 38 percent of the existing POG within the province is high-volume and 11 percent is large-tree POG. On NFS lands, 88 percent of the original POG remains, while on non-NFS lands only 46 percent remains. About 82 percent of the original NFS high-volume POG remains compared with only 33 percent of the original high-volume POG on non-NFS lands. Similarly, 74 percent of the original large-tree POG exists today on NFS lands, while only 16 percent of original large-tree POG remains on non-NFS lands. This province originally contained about 39,000 acres of POG on karst terrain. To date, about 36 percent of this karst POG has been harvested.

Effects of past harvest have been slight to non-existent on most portions of most of the islands in the province. However, extensive past harvesting on Heceta Island, on both NFS and non-NFS lands, have affected the biodiversity in a number of the watersheds.

Dall Island and Vicinity

This province is located at the extreme southwestern corner of Southeast Alaska and, like the Southern Outer Islands province, is subject to strong oceanic influences. Unlike the Southern Outer Islands province, the topography of the Dall Island and Vicinity province is rugged and dissected with abundant limestone outcrops. The province includes Dall Island and Long Island along with numerous small islands. Approximately 3 percent of the province is in congressionally protected land designations and only 56 percent of the province consists of Tongass National Forest lands. This province has the lowest proportion of NFS lands of any province within the Tongass Forest boundary. Other major landowners include: Sealaska Regional Corporation (29 percent); Klukwan Village Corporation (11 percent); Haida Village Corporation (1 percent); and the State of Alaska (1 percent).

The Dall Island and Vicinity province contains approximately 100,000 acres of POG and has experienced 33,000 acres of harvest, almost all of which is on non-NFS lands. Almost all of this harvest was conducted either in the 1980s or in the last 10 years (Appendix E), so the majority of the young growth is still in the stand initiation successional stage. Approximately 99 percent of the original POG remains on NFS lands, along with 99 percent of the original high-volume POG and 99 percent of the original large-tree POG. On non-NFS lands, 49 percent of the original POG is remaining, while 33 percent of the original high-volume POG and 8 percent of the original large-tree POG remains today, indicating substantial disproportionate harvest of large-tree POG. This province originally contained about 12,000 acres of POG on karst terrain. To date, at least 10 percent of this karst POG has been harvested.

Much of the past harvest took place on private lands on Long Island, where extensive stands of large-tree POG originally existed. The province is believed to have originally contained the best representation of large-tree karst forest in Southeast Alaska (Carstensen et al. 2007). The biodiversity of watersheds on much of northern Long Island has been substantially modified due to expansive harvesting in this area. This level of modification has also occurred in some watersheds on eastern Dall Island.

South Prince of Wales Island

The South Prince of Wales Island biogeographic province covers the southern quarter of Prince of Wales Island and is characterized by steep and rugged topography and a highly dissected coastline. It is relatively warm and wet and provides habitat for plant species that do not grow further north. Approximately 28 percent of the province is in congressionally protected land designations (South Prince of Wales Wilderness and Nutkwa LUD II) and the majority of the province is roadless. Non-NFS lands comprise about 8 percent of the land area, about two-thirds of which is owned and managed by Kootznoowoo Village Corporation. Haida Village Corporation, the State of Alaska, and other parties comprise the remaining owners.

The province currently contains about 173,000 acres of POG and has had about 18,000 acres of past harvest. With the exception of the Chasina Peninsula in the northeast, relatively little past harvest has occurred on NFS lands in the province (about 3,000 acres). As a result, approximately 98 percent of the original POG on NFS land remains. Non-NFS lands have been relatively heavily harvested (approximately 14,000 acres) with approximately 43 percent of the original POG remaining. Counting all ownerships, 91 percent of the original POG remains. Harvest is concentrated in the northern portion of the province on the Chasina Peninsula and along Cholmondeley Sound. Although high-volume and large-tree POG have been harvested at higher rates than smaller tree types, it is estimated that 88 percent of both high-volume and large-tree POG remains in the province on all lands combined. However, the percent of these types remaining is much lower in local areas with the highest rates of harvest (e.g., Chasina Peninsula and Cholmondeley Sound).

Extensive tracts of high-volume POG, including large-tree forests, occur within the northwestern portion of the province and are mostly protected within the Nutkwa LUD II area. Because of these tracts and other areas of high-volume and large-tree POG, these types make up high percentages of the existing POG relative to other Southeast Alaska provinces (51 and 29 percent, respectively).

One area of particular concern on the edge of this province is the Sulzer Portage, a relatively narrow neck of land on Prince of Wales Island connecting West Arm Cholmondeley Sound and Portage Bay at the head of Hetta Inlet. It joins the North Central Prince of Wales and the South Prince of Wales Island provinces and has had considerable past timber harvest. Due to recent land selections, the immediate portage is entirely on non-NFS lands. Substantial future harvest, if it were to occur, could substantially affect ecological connectivity. See the *Wildlife* section for a description of pinch-points and an analysis of the effects of additional development in these areas on wildlife movements.

North Misty Fiords

The North Misty Fiords province has considerable topographic relief and a cold, mainland-type climate with many glaciers. Vegetation occurs in long, narrow strips along river valleys and lower slopes of fiords. The province is 99 percent NFS lands and 82 percent of the province is protected within the Misty Fiords National Monument, which is in wilderness status. The State of Alaska is the only other major landowner with 1 percent of the province.

The province contains 201,000 acres of existing POG and only 2,000 acres of past harvest. Thus, 99 percent of the original POG, 98 percent of the original high-volume POG, and 95 percent of the original large-tree POG remains today. High-volume and large-tree POG represent 33 percent and 6 percent of the existing POG, respectively. Because of the low degree of past harvest, their effects are relatively minor throughout the province.

South Misty Fiords

The South Misty Fiords province has lower topographic relief and is warmer than the North Misty Fiords province, but otherwise it is typical of the other mainland provinces. Forest vegetation is more diverse than the other coastal provinces, and vegetation is less fragmented by rock and ice than the North Misty Fiords province. The southwestern portion of the province is rolling, nearly continuous muskeg with conifer forests in the bottoms and flats. Approximately 99 percent of the province is in congressionally protected land designations (Misty Fiords National Monument) and nearly 100 percent is on NFS lands. The State of Alaska is the only other major landowner with less than 1 percent of the province.

The province contains 310,000 acres of existing POG and no measurable past harvest. Thus, 100 percent of the original POG, 100 percent of the original high-volume POG, and 100 percent of the original large-tree POG remains today. High-volume and large-tree POG represent 31 percent and 5 percent of the existing POG, respectively. Because of the lack of past harvest, no effects from past timber harvest have occurred within the province.

Ice Fields

The Ice Fields province covers the highest mountains along the eastern boundary of Southeast Alaska with Canada. It is dominated by permanent ice fields, active glaciers, and nunataks (mountain peaks between glaciers). Approximately 33 percent of the province is in congressionally protected land designations (wilderness or national monument) and nearly 100 percent is on NFS lands. The State of Alaska is the only other major landowner with less than 1 percent of the province.

The province contains 115,000 acres of existing POG in narrow bands along mountain valleys, and 4,000 acres of past harvest. Thus, 97 percent of the original POG, 93 percent of the original high-volume POG, and 83 percent of the original large-tree POG remains today. High-volume and large-tree POG represent 32 percent and 5 percent of the existing POG, respectively. Because of the low level of past harvest in this province, the effects of past harvest are localized and relatively minor throughout the province.

Chilkat River Complex

The Chilkat River Complex lies at the northern end of the Inside Pasage and is outside the Tongass Forest boundary. It consists of tall ridge systems, large glacial rivers, and includes glaciers and snowfields. Many of the rivers and drainage basins extend across the international boundary into Canada. Because of the overlap of coastal and interior floras and faunas, the province contains Alaska's highest vascular plant species richness and the highest mammalian diversity in Southeast Alaska (Carstensen et al. 2007). The province is located outside the Tongass Forest boundary and has 2 percent of its lands in a congressionally protected status. Although an additional 10 percent is administratively protected, the province has the lowest overall percentage of lands in a status that restricts development of all Southeast Alaska provinces. Approximately 59 percent of the province consists of state lands, including the 286,000-acre Haines State Forest, the 45,000-acre Chilkat Bald Eagle Preserve, and 242,000 acres of other state lands. The Bureau of Land Management manages about 39 percent of the province, small edges of Glacier Bay National Park represent about 1 percent, and other landowners, including the cities and boroughs of Haines and Skagway, comprise the remaining 1 percent.

The province contains about 145,000 acres of POG and about 21,000 acres have been harvested. The result is that approximately 88 percent of the original POG in the province remains today. Large-tree POG has been harvested at a higher rate; about 73 percent remains. However, about 89 percent of the original high-volume POG is estimated to remain, indicating a non-disproportionate harvest for the high-volume POG types as a group.

Although only about 13 percent of the original POG in the province has been harvested, about 27 percent of the large-tree POG has been logged and harvest has been concentrated within the Haines State Forest near the confluences of the Chilkat River with the Klehini and Kelsall Rivers. Thus, the effects of past harvest in these local areas have been relatively high.

Glacier Bay/Fairweather Range

The Glacier Bay/Fairweather Range province is the largest province in Southeast Alaska (2.5 million acres), but the vast majority of it is high mountains and glaciers and the majority is non-vegetated. The highest peaks are in the Fairweather Range along the western edge of the province, with Mt. Fairweather at over 15,000 feet. A large flat, foreland, the Gustavus Foreland, occurs in the area around Gustavus and to the north in the Bartlett River valley. Lowlands are also fairly extensive along the Dundee River and other smaller drainages on the southwest side of Glacier Bay. Glacier Bay National Park protects virtually the entire province (97 percent), except for about 75,000 acres in the vicinity of Gustavus. There are no NFS lands in the province.

Although approximately 171,000 acres of POG exist in the lowlands of the province, only a small fraction (< 0.5 percent) has been harvested. High-volume POG makes up the vast majority of the POG in the province (an estimated 92 percent), but large-tree POG is relatively rare (< 1 percent).

The effects of past harvest on the biodiversity and old-growth ecosystem integrity of the province has been insignificant because of the insignificant amount of past harvest. Primary succession of natural young-growth forests will contribute to the extent of POG over time.

Fragmentation

The Tongass National Forest is characterized by fragmentation on many scales and this fragmentation is the result of different processes. Fragmentation occurs when large blocks of habitat are broken into smaller parcels by natural (e.g., wind throw, landslides, soil slumping, erosion, insects and diseases, and avalanches) or human induced (e.g., roads or timber harvest operations) forces. From a regional perspective, the Tongass National Forest is highly fragmented due to numerous islands and dramatic topographic relief. At a landscape level across the project area, the natural distribution of POG forest is quite patchy and is linear in many areas, with fragmentation created by muskeg, forested wetlands, and alpine areas.

On a small scale, single-tree gaps within a 400-year-old Sitka spruce stand provide habitat for forest interior birds such as the hairy woodpecker. On a broader scale, large patches of wind disturbance of 10 acres or more may create nesting habitat for migratory songbirds, or increase the growth of understory forage for some species such as deer.

Timber harvest operations, including road-building, add to the level of fragmentation or edge that occurs naturally. The effect of timber-harvest varies with the placement of units and their proximity to large existing forest blocks. Simulation studies have indicated that when 50 percent of a watershed is harvested with a staggered setting design, little if any interior forest remains. As habitat becomes fragmented, residual habitat patches become smaller and more isolated from each other. Whether a particular patch pattern and degree of fragmentation is beneficial or deleterious depends largely on the characteristics of the species using the landscape (Morrison et al. 1992). Some species, particularly those with limited mobility such as small mammals may view open spaces (natural or human-induced) as travel barriers. Fragmentation may increase the risk of predation by avian, and mammalian carnivores, or increase isolation between other subpopulations which in turn may increase the risk of local extirpation.

Timber harvest tends to increase forest fragmentation and the amount of forest edge. The edges between different forest types, and between forested and non-forested areas, can affect the environment close to the edge. For example, forest edges tend to be warmer in the summer and cooler in the winter than interior forests (Franklin 1993). Some species increase in abundance close to an edge while others decrease in abundance. Species associated with interior forests but not with forest edges are of concern since timber harvest tends to decrease the amount of interior forest. Concannon (1995) noted that the edge effect or depth-of-edge influence distance varied by such factors as forest type, tree density, site aspect, slope, solar insolation, aspect, slope, latitude, season, and edge type (e.g., peatland, shoreline). Edge effects ranged from 30 to over 200 meters (from approximately 100 feet to over 660 feet) from an edge. Edge effects change as forest grows; however, there is little information on how that may reduce overall effects over time.

Patches of old-growth forest sometimes serve as the only habitat in a landscape for many lichens, fungi, bryophytes, plants, and small-bodied animals, all of which contribute to the biodiversity and productivity of the forest ecosystem. These patches may be critical for species that are locally endemic, occur only in very specific conditions of forest structure or soil, or have limited dispersal capabilities. These issues are typically assessed in detail during project-level analysis.

The framework of the old-growth forest conservation strategy in the current Forest Plan consists of a network of small, medium, and large old-growth reserves (OGRs), specifically designed to conserve habitats of the species that have the most viability concerns. It was designed, in part, to recognize and account for current conditions within each biogeographic province, and to better maintain future old-growth forest in provinces where past harvest has been high. A second component of the old-growth forest conservation strategy in the 1997 Forest Plan is the set of standards and guidelines that protect specific areas (e.g., 1,000-foot-wide beach fringe) and provide habitat connectivity in those areas with LUD allocations that permit commercial timber harvest.

To preserve the integrity of the old-growth ecosystem on the Tongass National Forest, project-level analyses are conducted at the landscape scale to identify blocks of contiguous old-growth forest within already identified large and medium reserves and other natural setting LUDs. Landscape connectivity among these blocks is evaluated during this analysis (see Chapter 4 of the Forest Plan, Landscape Connectivity Standard and Guideline).

Intact Watersheds

Another way of evaluating fragmentation and biodiversity in general is through considering the degree to which areas have been modified or developed by humans on a large watershed scale and then assessing effects on the watersheds that have undergone little if any previous modification. For this analysis, the VCU is used to define large watersheds. VCUs are Tongass land divisions with boundaries that typically follow watershed divides and encompass one or more stream systems. There are about 945 VCUs on the Tongass and they average about 18,000 acres in size.

Intact watersheds are defined here as those having less than 5 percent of their POG harvested, which is consistent with a similar analysis conducted by Audubon Alaska and The Nature Conservancy (Albert and Schoen 2007). This measure provides land managers with a means to assess the extent to which the Tongass consists of intact, undeveloped, and fully functional landscapes (a measure of conservation representation), and provides a means of assessing future changes expected under various management alternatives. Fully functional landscapes are defined as areas that maintain focal species, communities, and/or systems, and their supporting ecological processes within their natural ranges of variability (Poiani et al. 2000). Thus, functional landscapes are an important element in the conservation of biodiversity and can be used as a means to identify areas of biological importance. The use of a 5 percent POG harvest criterion for this classification is not meant to imply that a watershed must exceed this threshold to be fully functional. It is highly likely that many watersheds remain fully functional at harvest levels significantly above this level. It is used simply to provide an index or a measure of the proportion of watersheds that are intact and in relatively pristine condition.

Table 3.9-11 summarizes the number and acreage of intact large watersheds within each biogeographic province inside the Tongass Forest boundary. Overall, approximately 67 percent of the large watersheds and 72 percent of the acreage are estimated to be intact. Biogeographic provinces with the highest acreages of intact watersheds include the six biogeographic provinces along the mainland south of Skagway and the Admiralty Island province. Others that contain at least 0.5 million acres in intact watersheds include the East Chichagof, West Baranof, and Lynn Canal provinces. Those provinces with less than 50 percent of their large watersheds considered to be intact include Kupreanof/Mitkof, Etolin Island and Vicinity, and North Central Prince of Wales. Audubon Alaska and The Nature Conservancy (Albert and Schoen 2007) conducted a similar comparison of watersheds with greater than 95 percent of POG intact for all of Southeast Alaska. They found that approximately 71 percent of the landbase in Southeast Alaska still exists within these intact landscapes, and that much of this area was concentrated along the rugged mainland coast and Glacier Bay.

Table 3.9-11
Number and Acreage of Existing Intact* Large Watersheds (VCUs) by Biogeographic Province within the Tongass Forest Boundary

	Biogeographic Province	Total Number of Large Watersheds (VCUs) 1/	Percent of Intact Large Watersheds (VCUs) 1/	Approximate Total Acreage in Large Watersheds	Percent of Acreage in Intact Large Watersheds
1	Yakutat Forelands	24	83%	344,231	80%
2	Yakutat Uplands	26	96%	916,929	99%
3	East Chichagof Island	87	53%	1,129,840	49%
4	West Chichagof Island	31	100%	287,518	100%
5	East Baranof Island	22	55%	394,381	60%
6	West Baranof Island	43	65%	797,901	69%
7	Admiralty Island	60	88%	1,085,689	85%
8	Lynn Canal	50	76%	671,845	80%
9	North Coast Range	49	90%	1,111,396	94%
10	Kupreanof/Mitkof Island	35	37%	842,334	39%
11	Kuiu Island	30	73%	493,252	60%
12	Central Coast Range	29	79%	729,163	85%
13	Etolin Island	27	33%	518,932	30%
14	North Central Prince of Wales	116	24%	1,488,826	17%
15	Revilla Island/Cleveland Peninsula	84	68%	1,347,381	71%
16	Southern Outer Islands	20	50%	223,986	64%
17	Dall Island and Vicinity	35	71%	200,222	53%
18	South Prince of Wales	36	78%	395,076	75%
19	North Misty Fiords	32	94%	975,904	96%
20	South Misty Fiords	54	100%	906,047	100%
21	Ice Fields	57	93%	3,006,309	94%
	Total	**947**	**69%**	**17,867,163**	**74%**

[1] Intact is defined here as those watersheds having less than 5 percent of their POG harvested and not containing other major disturbances (e.g., large mines, communities, major roads).

Endemism

Endemic species are species that are isolated to islands or specific geography that potentially have an increased risk of adverse effects associated with management or natural disturbance. For example, these species may not be able to travel between islands or may be adapted to living in a very specific habitat that has a limited distribution. Species tied to island archipelagos are more sensitive to the effects of introduced non-natives, including pathogens and disease, and natural events, such as climate change, than other managed landscapes due to their limited mobility and isolation from other subpopulations (Cook et al. 2006). Therefore, there is a higher probability of extinction on islands. Risk assessment panels, convened prior to the 1997 Forest Plan, determined that endemic mammals were the most sensitive of all wildlife species to future landscape disturbances, such as that resulting from timber harvesting (Swanston et al. 1996). Such disturbances affect the likelihood of maintaining viable, well-distributed populations of endemic mammals across the Forest.

Southeast Alaska has been found to be a region with an especially high degree of endemism in its small mammal fauna, principally because of its archipelago geography combined with highly dynamic glacial history and resulting natural “pinch points” or "bottle-necks" where natural features (e.g., mountains or water bodies) or human caused features (e.g., roads and harvest units) constrain potential movement by wildlife to narrow bands of habitat. For example, some islands do not support particular species even though suitable habitat exists (e.g., there are no brown bears on Prince of Wales Island or wolves on Admiralty, Baranof, or Chichagof islands). Other species have restricted habitat requirements. Small mammals appear to be most diverse in scrub and herbaceous habitat associations and were least abundant and diverse in closed-canopy, even-aged (young growth) coniferous forest types and pine muskegs (MacDonald and Cook 2000). Between 1990 and 2005, 111 islands on the Tongass were surveyed for mammals, though much of this effort occurred prior to 2000 (Tongass Conservation Strategy Review Workshop 2006). This has resulted in the documentation of new distributions, new species, and distinct populations that also suggest a high level of endemism on the Tongass (see the *Wildlife* section for additional discussion). There continue to be gaps in knowledge about the natural history, ecology, and distribution of wildlife subspecies indigenous to Southeast Alaska (Hanley et al. 2005), and continued research will help to fill current gaps for some species. Additional species-specific discussion can be found in this chapter under the *Wildlife*, *Plant*, and *Fish* sections.

Invasive Species

Alaska has, until recently, been relatively isolated from invasive species, due to climatic conditions, large undeveloped areas, limited transportation routes, and sparse human population centers (Fay 2002). Schrader and Hennon (2005) assessed the current status of invasive species in Alaska's ecosystems, which include non-native plants, fish, wildlife, and other species, emphasizing the Chugach and Tongass National Forests. More than 130 non-native plant species have been recorded in Alaska through 2005 (AKEPIC 2006). Eighty-eight species of non-natives have been recorded on the Tongass, 46 have an invasiveness ranking according to their invasive characteristics and threat to Alaska, with 29 of those species identified as having a greater potential threat to Alaska. Fifteen of the species found on the Tongass are among the species that pose a greater potential threat (see the *Plant* section in this chapter for additional discussion on non-native plants).

Although many non-native wildlife species have been introduced or transplanted in Alaska, with the exception of rats in coastal ecosystems and possibly slugs in estuaries, none is considered invasive at the present. Additional discussion on terrestrial wildlife invasives are discussed in the *Wildlife* section of this chapter.

Schrader and Hennon (2005) identified 11 aquatic species in their assessment. Six species have already established breeding populations in National Forest lands and other areas in Alaska and include northern pike (*Esox lucius* Linnaeus), yellow perch (*Perca flavescens*), redlegged frog (*Rana aurora*), Pacific chorus frog (*Pseudacris regilla*), rainbow trout (*Oncorhynchus mykiss* Walbaum), and brook trout (*Salvelinus fontinalis*). The other five species are not established in Alaska yet, but cause widespread problems in the lower 48 states and could become problematic in Alaska. These species of concern are the Atlantic salmon (*Salmo salar)*, Chinese mitten crab (*Eriocheir sinesis*), New Zealand mudsnail (*Potamopyrgus antipodarum* Gray), goldfish (*Carassius auratus*), and the signal crayfish (*Pacifacstacus leniusculus*). In Alaska, established populations of northern pike (with the exception of Pike Lakes on the Yakutat Ranger District) pose the greatest immediate concern, while the Atlantic salmon, Chinese mitten crab, and New Zealand mudsnail species are likely to invade Alaska in coming years (Fay 2002). Invasive tree pathogens are not currently damaging Alaskan ecosystems, but there are numerous species that could cause widespread tree mortality if introduced.

Four introduced insects are currently established in Alaska: the larch sawfly, alder woolly aphid, spruce aphid, and amber-marked birch leafminer. These insects can cause widespread tree defoliation and mortality. A number of exotic insects pose a potential threat and are related primarily to transport of infested plant and wood products.

Managing invasive species on the Tongass National Forest will likely be challenging in the future. Increased public awareness at all levels coupled with interagency cooperation and development of cooperative management partnerships is needed to limit invasive species populations at current levels in Alaska.

The Forest Service is addressing invasive plant management through the Alaska Region Invasive Plant Strategy (USDA Forest Service 2005a) and the Tongass National Forest Invasive Plant Management Guides (Lerum and Krosse 2005). Within the Forest Service, various approaches are in place to address four action elements (prevention, early detection and rapid response, control, and restoration) in the National Strategy and Implementation Plan for Invasive Species Management (USDA Forest Service 2004f). See the *Plants* section in this chapter for more information on management of non-native plant species.

Environmental Consequences

Old-growth forests, which cover more than half of the 16.8 million acres of the Tongass, provide the primary habitat for the majority of terrestrial plant and animal species. They also represent ecosystems with uniquely defined characteristics and are the habitat types most affected by timber management activities; therefore, they are the most affected ecosystems on the Tongass, and the following discussion focuses on general effects on old-growth forest ecosystems.

Direct and Indirect Effects

This analysis of effects on biodiversity is subdivided into a number of sections. The first section focuses on effects associated with anticipated changes to old-growth forest representation over time, related to timber harvest. Associated with the evaluation of the effects on representation, are the effects on the elements of the old-growth forest conservation strategy for each alternative, including the coarse-filter (forest-wide system of old growth reserves) and fine-filter (standards and guidelines) components. Smaller sections address the effects on fragmentation and intact watersheds, endemics, and invasive species. The final section of this analysis evaluates the cumulative effects on biodiversity of the proposed Forest Plan adjustment in conjunction with past, present, and reasonably foreseeable activities on both NFS) and non-NFS lands (including private, state, and other ownerships).

Measurement of Effects

To quantify potential effects on biodiversity, the alternatives can be compared in terms of their ability to maintain a functional and interconnected old-growth ecosystem. Functional refers to the ability of an ecosystem to maintain or contribute to the maintenance of populations that use it, and to contribute to the diversity and productivity of other ecosystems. Examples of ecosystem functions include providing habitat for organisms, climatic buffering, soil development, and the maintenance of soil productivity through inputs of coarse woody debris, nitrogen fixation, spread of biotic and abiotic disturbance through landscapes, and nutrient cycles.

The interconnectedness of an ecosystem is a measure of the extent to which the landscape pattern of the old-growth ecosystem provides for biological and ecological flows to sustain old-growth associated animal and plant species across the Tongass and Southeast Alaska. Connectivity does not necessarily mean that old-growth areas need to be physically joined in space, because most associated species can disperse across areas that are not in old-growth ecosystem conditions. Landscape features affecting connectivity of old-growth ecosystems include the distances between old-growth reserve areas and forest conditions in the areas between the reserve areas (matrix lands).

Given that Southeast Alaska consists of many islands, connectivity issues should include landscape level connections between individual islands as well as between islands and the mainland portion of Southeast Alaska; however, current and future forest management activities are expected to have a greater influence on within-island conditions than between islands. Forest management areas require measures that ensure wildlife movement patterns and habitat diversity are protected over time. This is an important consideration when analyzing functional landscape connectivity and the maintenance of well-distributed, viable populations. Several “pinch-points“ or "bottle-necks" where natural features or human-caused features (e.g., roads and clearcuts) constrain potential movement by wildlife to narrow bands of habitat have been identified on the Tongass and are discussed in greater detail in other places within this section and under the *Wildlife* section of this chapter.

Fragmentation associated with habitat loss results in smaller sizes of habitat patches available to a species, increased distances among habitat patches, increased amounts of matrix conditions in which habitat patches are embedded, and altered spatial distribution of habitat types (Haufler 2006). These factors are strongly tied to the structural and functional connectivity of the landscape, and thus the ability of the landscape to support well-distributed and viable wildlife populations.

By maintaining a functional and interconnected old-growth ecosystem, it can be assumed that various components of biodiversity, including structural diversity (within-stand and landscape level), connectivity (unfragmented, contiguous blocks of old growth), stand age and species composition (including understory species), and ecological processes (e.g., tree establishment, disturbance, and nitrogen fixation) will also be maintained. The amount and distribution of POG after 100 years of Forest Plan implementation can serve as a relative indicator of the functioning and interconnectedness of the old-growth ecosystem and the potential effects on biodiversity under each alternative.

In addition, effects on biodiversity can be measured by the degree of change expected to occur in the composition and distribution of the old-growth ecosystem relative to its historic composition and distribution. It can be assumed that the more an alternatives change the natural distribution and composition of old-growth ecosystems, the greater are its effects on biodiversity. Therefore, the effects of the alternatives on the distribution and composition of old-growth forests can be evaluated by examining the representation of POG and specific types of POG across the Tongass, with reference to historical representation. At the same time the analysis examines the old-growth conservation strategy of each alternative and the degree to which it maintains old-growth function, interconnectedness, and representation.

Another measure of the effects of the alternatives on landscape fragmentation can be obtained by evaluating the degree to which the alternatives would result in converting large, relatively pristine watersheds to a modified state (see *Intact Watersheds* in the *Affected Environment* part of this section). For this analysis, VCUs are used to define large watersheds and intact large watersheds are defined as those having less than 5 percent of their POG harvested and not containing other major disturbances. The use of VCUs and a 5-percent threshold are not based on specific criteria for defining intact large watersheds. Therefore, this measure should be viewed as one measure or an index of ecosystem fragmentation.

Finally, one additional tool is used in the comparison of the alternatives. The 1997 Forest Plan Revision Final EIS biodiversity analysis (U.S. Forest Service 1997a) relied in part upon expert panel evaluations of alternatives in terms of the estimated relative risks to the old-growth ecosystem (DeGayner 1996). This old-growth panel assessment is referred to below, where appropriate. Although the alternatives evaluated by the panel evaluations do not exactly correspond to the alternatives evaluated here (the old-growth reserve system and many new standards and guidelines were being developed and evaluated during the 1997 Forest Plan Revision), useful inference about the relative risks of the current alternatives can be made. Panel assessments were also conducted for wildlife and fish species and these are discussed in the *Wildlife* and *Fish* environmental effects sections.

Conservation Strategy Overview

An integrated old-growth conservation strategy was developed and incorporated into the 1997 Forest Plan (Appendix D). This strategy has two basic components. The first is a forest-wide reserve network that protects the integrity of the old-growth forest by retaining blocks of intact, largely undisturbed habitat. The old-growth reserves include a system of large, medium, and small Habitat Conservation Areas allocated to the Old-growth Habitat Land Use Designation (LUD), and full protection of all islands less than 1,000 acres in size. The reserve network also includes all other non-development LUDs. These include Wilderness, National Monument, Legislated LUD II, Wild River, Remote and Semi-remote Recreation, Research Natural Area, Municipal Watershed, and all other LUDs that essentially maintain the integrity of the old-growth ecosystem. The old-growth reserves were specifically designed to conserve habitats of the species that have the greatest viability concerns. They were designed, in part, to recognize and account for current conditions within each biogeographic province, and to better maintain future old-growth forest in provinces where past harvest has been high. The second component of the old-growth habitat conservation strategy is management of the matrix, e.g., the lands with LUD allocations where commercial timber harvest may occur. Within the matrix, components of the old-growth ecosystem are maintained by standards and guidelines to protect important areas and provide old-growth forest habitat connectivity. This component includes the beach and estuary fringe, riparian buffers, and a variety of other categories where timber harvest is not permitted. Matrix lands play a vital role in providing functional connectivity across fragmented landscapes (Szacki 1999). A detailed description of the rationale and components of the strategy is provided in Appendix D.

Research since 1997 has provided much new information on plant and wildlife populations and habitat relationships in Southeast Alaska; however, there continue to be gaps in knowledge about the ecology and distribution of many species making direct correlations between land management activities and their habitats and/or population impacts difficult. The conservation strategy itself is a step toward addressing this uncertainty by maintaining an extensive network of reserves and landscape connectivity on the Tongass; however, the effectiveness of the reserves and buffers in relation to their size, landscape pattern, and geographic distribution has yet to be scientifically tested (Powell et al. 1997). Smith (2005) noted that for many species, it is unknown whether the current reserve design is capable of supporting well-distributed, viable populations or providing sufficient connectivity to enable the flow of individuals between reserves. In addition to the unknowns related to the reserve network, there is also a need to explicitly define future desired conditions of matrix lands which provide life requisites for many species and to determine the optimal way to manage young-growth to benefit wildlife (*Workshop Integration Session*, Tongass Conservation Strategy Review Workshop 2006); new approaches to stand management that offer alternatives to clearcutting are also being evaluated.

The conservation strategy developed for the 1997 Forest Plan Revision is incorporated directly in Alternative 5, which represents the current Forest Plan. Each alternative incorporates a variation of the current old-growth conservation strategy by maintaining some level of old-growth reserves and providing additional old-growth protection within the matrix. These variations in the strategy are evaluated below.

General Overview of Effects

An overview of the degree to which old-growth forest protection is afforded by the old-growth strategy of each alternative is provided by examining the amount and percent of POG that occurs in reserves (areas where old-growth harvest is generally not permitted) versus the amount and percent in the matrix (areas where forests are actively managed). Table 3.9-12 presents a detailed summary of this information for each alternative. This table also identifies the composition of POG in various categories by summarizing all POG, high-volume POG, and large-tree POG.

Table 3.9-12
Estimated Acreage and Percentage of All Existing POG, High-Volume POG, and SD67 POG in Reserves[1] and Matrix[2] Lands (minimum protected vs. maximum harvested) by Alternative[3]

		Amount in Reserves[1]		Amount in Matrix[2] Minimum Protected		Amount in Matrix[2] Maximum Harvested[4]		Total Existing POG	
Alt.	POG Category	Acres	Percent	Acres	Percent	Acres	Percent	Acres	Percent
1	All POG	4,615,995	93%	249,182	5%	85,972	2%	4,951,148	100%

	SD67 POG	287,295	53%	144,188	27%	105,968	20%	537,451	100%

[1] Reserves include all Non-Development LUDs (e.g., Old-Growth Habitat, Semi-Remote Recreation, Remote Recreation, Wilderness, National Monument, etc.).
[2] Matrix includes all Development LUDs (Timber Production, Modified Landscape, Scenic Viewshed, and Experimental Forest).
[3] Numbers may not appear to sum correctly due to rounding.
[4] Maximum harvested assumes the maximum allowed by the Allowable Sale Quantity is harvested each decade. The estimate assumes all scheduled suitable POG is harvested [calculated by subtracting alternative-specific reduction factors for the Model Implementation Reduction Factor (MIRF) and scheduling from the mapped suitable acreage under each alternative (see the *Timber* section)].

The alternatives cover a wide range of old-growth effects from minimal effects associated with Alternative 1, which has a maximum old-growth harvest of 86,000 acres, to substantially greater effects associated with Alternative 7, which has a maximum old-growth harvest of 807,000 acres. This broad range results in from 57 to 93 percent of the existing POG on the Tongass being maintained within reserves, with an additional amount of POG being protected from harvest by standards and guidelines in the matrix. Maximum POG harvest would range from 2 percent to 16 percent of existing POG. Harvest of high-volume and large-tree POG would range from 2 to 18 percent and from 3 to 20 percent, respectively. Placing the alternatives in order from lowest to highest maximum POG harvest results in the following ranking: Alternatives 1, 2, 3, 6, 5, 4, and 7.

Table 3.9-13
Estimated Acreage and Percentage of Young Growth[1] in Reserves[2] and in Matrix[3] Lands (minimum protected vs. maximum harvested) by Alternative[4]

Alternative	Amount in Reserves[2]		Amount in Matrix[3] Minimum Protected		Amount in Matrix[3] Maximum Harvested[5]		Total Existing Young Growth	
	Acres	Percent	Acres	Percent	Acres	Percent	Acres	Percent
1	189,528	42%	208,624	46%	56,573	12%	454,724	100%
2	96,452	21%	189,840	42%	168,432	37%	454,724	100%
3	88,097	19%	182,289	40%	184,339	41%	454,724	100%
4	55,024	12%	187,627	41%	212,073	47%	454,724	100%
5	72,930	16%	176,753	39%	205,037	35%	454,724	100%
6	83,045	18%	171,601	38%	200,075	44%	454,724	100%
7	35,426	8%	183,700	40%	235,599	52%	454,724	100%

[1] Young growth in this table includes only young growth originating from past timber harvest. It does not include natural young growth (e.g., from blowdown), which is assumed to either be harvested or converted back to young growth naturally.
[2] Reserves include all non-development LUDs (e.g., Old-Growth Habitat, Semi-Remote Recreation, Remote Recreation, Wilderness, National Monument, etc.).
[3] Matrix includes all development LUDs (Timber Production, Modified Landscape, Scenic Viewshed, and Experimental Forest).
[4] Numbers may not appear to sum correctly due to rounding.
[5] Maximum harvested assumes the maximum allowed by the Allowable Sale Quantity is harvested each decade. The estimate assumes all scheduled suitable young growth is harvested [calculated by subtracting alternative-specific reduction factors for the Model Implementation Reduction Factor (MIRF) and scheduling from the mapped suitable acreage under each alternative (see the *Timber* section)].

In addition, to the harvest of POG, each alternative designates a portion of the existing young growth to be set aside and not harvested. Table 3.9-13 summarizes these areas and the amounts to be included in reserves, in the matrix, and the amount potentially harvested. There would be a range of approximately 219,000 to 398,000 acres of existing productive young growth that would not be harvested and that would eventually develop into mature forest and then POG. Based on the fact that most of this young growth is currently 20 to 40 years old (see Table 3.9-8), after about 70 years when the majority of the POG harvest has taken place, this young growth will be maturing and potentially beginning to take on some older forest characteristics, particularly if subjected to thinning or other types of stand management. Based on the historical overharvest of high-volume and large-tree POG (see *Affected Environment* part of this section), a high proportion of this young growth will be on high-site index lands, indicating faster than average growth rates.

The future and historical distribution of POG harvest by biogeographic province is represented in Table 3.9-14, which shows the percent of existing POG relative to the original POG, and the percent of original POG remaining after 100+ years of implementation for each alternative. In addition, Table 3.9-14 shows the percent of original POG that would be remaining, after 100+ years, inside reserves designated by the Forest Plan for each alternative. POG harvest would occur in 18 of the 21 provinces in at least one alternative. The range of the alternatives is 9 provinces containing some harvest under Alternative 1 to 18 provinces containing harvest under Alternative 7. Most of harvest in all alternatives would come from four biogeographic provinces in the south-central portion of the Tongass (North Central Prince of Wales Island, Kupreanof/Mitkof Island, Revilla Island/Cleveland Peninsula, and Etolin Island).

Table 3.9-14
Estimated Percent of Original POG Remaining Forest-wide (1st number) and in Reserves (2nd number) in 100+ Years Assuming Maximum POG Harvest[1] under Each Alternative by Biogeographic Province

[1] The estimated suitable POG incorporates a reduction factor for the Model Implementation Reduction Factor (MIRF) and scheduling, which reduces mapped suitable acres to the estimated scheduled acres for each biogeographic province (see the *Timber* section).
[2] Percentage of original POG. Harvest of suitable old growth is estimated to occur until approximately until the year 2105
[3] Expressed as a percent of original POG

Effects on the largest tree categories of old growth and on old-growth growing on karstlands are of particular concern because past timber harvest has concentrated in these stands. In the following discussion the largest tree categories are represented in two ways: high-volume and large-tree POG. High-volume POG includes the three (out of seven) SDM classes that generally represent the most productive sites, produce the highest timber volumes, and contain the largest trees (SD5N, SD5S, and SD67). Large-tree POG is defined as the SD67 class (typically the type with the highest density of large trees) by itself. Tables 3.9-15 and 3.9-16 present information similar to Table 3.9-14, but for high-volume POG and large-tree POG relative to the original amounts of each of these POG categories by biogeographic province. Harvest of karstlands is summarized in Table 3.9-17, which shows the percent of existing karst POG relative to the original karst POG acres, and the percent of original karst POG remaining after 100+ years of implementation for each alternative. Impacts on biodiversity could be expected to be greatest in those areas that have the highest cumulative harvest percentages of the various POG categories, because they are more susceptible to greater losses of biodiversity components associated with POG forests.

Under all alternatives, long-term POG representation by ecological subsection would be maintained by protecting at least 41 percent of original POG in all 73 subsections (Table 3.9-18). At least 90 percent of original POG would be maintained in 25 (Alternative 7) to 51 (Alternative 1) of the 73 subsections and at least 75 percent would be maintained in 45 (Alternative 7) to 69 (Alternative 1) out of the 73 subsections.

The effects of the alternatives on the number, acreage, and percentage of intact large watersheds are summarized in Table 3.9-19. An intact watershed is defined, for the purpose of this ananlysis as one in which less than 5 percent of the original POG has been harvested. Currently, 69 percent of the large watersheds on the Tongass, which converts to 74 percent of the acreage, are considered intact. After 100+ years of implementation of the alternatives, giving consideration to additional harvest on non-NFS lands, these percentages would range from 60 percent of the watersheds (68 percent of the acreage) under Alternative 1 to 47 percent of the watersheds (57 percent of the acreage) under Alternative 7. Approximately 8 percent of the drop in percentage of intact watersheds and 5 percent of the drop in acreage would be due to additional development on non-NFS lands.

Effects by Alternative

The following subsections summarize the biodiversity effects associated with each alternative with reference to the data presented in Tables 3.9-12, 3.9-13, 3.9-14, 3.9-15, 3.9-16, 3.9-17, 3.9-18, and 3.9-19.

Alternative 1

Alternative 1 would have the lowest effect on biodiversity among the alternatives, primarily because it would result in the lowest harvest and the highest POG acreage in reserves. Although this alternative was not specifically evaluated in the 1996 panel assessment, based on its level of harvest and other factors considered in the assessment, it is clear that the assessment would have confirmed this ranking.

Alternative 1 would maintain 93 percent of the existing POG within reserves and an additional 5 percent would be protected in the matrix by standards and guidelines or not scheduled for harvest. As a result, only 2 percent or 86,000 acres would be subject to harvest (Table 3.9-12). Long-term maximum harvest of high-volume and large-tree POG are also projected to be in the 2 to 3 percent range. In addition, there would be about 398,000 acres of existing productive young growth that would not be harvested and that would eventually develop into mature forest and then POG (Table 3.9-13). This represents about four times as much as the maximum POG harvest.

Assuming maximum harvest over 100+ years, approximately 90 percent of the original POG would remain Forest-wide; 85 percent of the original POG would be in reserves (Table 3.9-14). Harvest would be conducted in 9 out of 21 provinces occupied by the Tongass, but only 5 provinces would have potential harvest exceeding 5,000 acres. At least 15 of the 21 provinces would have more than 90 percent of their original POG remaining after 100+ years, and only 1 province, North Central Prince of Wales, would have less than 75 percent remaining (Table 3.9-14).

Table 3.9-18
Estimated Percentage of Original POG Remaining Forest-wide in 100+ Years Assuming Maximum POG Harvest[1] under Each Alternative by Ecological Subsection

[1] The estimated suitable POG incorporates a reduction factor for the Model Implementation Reduction Factor (MIRF) and scheduling, which reduces mapped suitable acres to the estimated scheduled acres for each ecological subsection (see the *Timber* section).

Relative to the largest tree categories, after 100+ years of maximum implementation of Alternative 1, 86 percent of the original high-volume POG and 78 percent of the original large-tree POG would remain, with the vast majority of these acres in reserves (Tables 3.9-15 and 3.9-16). At least 13 of the provinces would maintain 90 percent or more of their original high-volume POG and 2 provinces would maintain less than 75 percent (minimum = 60 percent for North Central Prince of Wales) (Table 3.9-15). Relative to large-tree POG, at least 9 provinces would maintain 90 percent or more of their original acres and 8 provinces would have less than 75 percent (minimum = 33 percent for East Baranof) (Table 3.9-16).

Implementation of Alternative 1 would result in a maximum reduction of the karst POG on the Tongass from 69 percent of the original karst POG at present, to 65 percent after 100+ years. Low elevation karst POG would be reduced from 62 percent currently, to 58 percent (Table 3.9-17).

Long-term POG representation by ecological subsection would be maintained under Alternative 1 by protecting at least 52 percent of the original POG on NFS lands in all 73 subsections (Table 3.9-18). At least 90 percent of original POG would be maintained in 51 of the 73 subsections and at least 75 percent would be maintained in 69 out of the 73 subsections.

If one considers the regrowth of current young growth that would be protected under this alternative (Table 3.9-13), after 100+ years the equivalent of an additional 7 percent of the original POG acres would be in mature forest stands and some stands would be at the beginning stages of exhibiting older forest characteristics (Table 3.9-14). Similarly, an additional 11 percent of the original high-volume POG, 17 percent of the original large-tree POG, and 26 percent of the original karst POG would be in mature forest stages (Tables 3.9-15, 3.9-16, and 3.9-17, respectively). In summary, after 100+ years of implementation under Alternative 1, 97 percent of the original POG would be remaining as POG or in mature forest stages. Likewise, 97 percent of the original high-volume POG would still be in high-volume POG or in mature forest stages, 95 percent of the original large-tree POG would be remaining as large-tree POG or in mature forest stages, and 91 percent of the original karst POG would be remaining as POG or in mature forest stages.

Alternative 1 would result in the additional conversion of intact large watersheds to a modified condition. After 100+ years of implementation under maximum harvest, the percentage of intact watersheds would be reduced from 69 percent to 60 percent of the Tongass. Similarly, the percentage of the land area of the Tongass in intact watersheds would be reduced from 74 percent to 68 percent (Table 3.9-19).

However, the majority of this reduction would occur as a result of additional development on non-NFS lands, even if no additional Tongass harvest occurred. Approximately 8 percentage points of the drop in percentage of intact watersheds and 5 percentage points of the drop in acreage are due to additional development on non-NFS lands.

Table 3.9-19
Estimated Percent of All Large Watersheds[1] in each Biogeographic Province Defined as Intact[2] After 100+ Years[3] of Forest Plan Implementation under Each Alternative

[1] Large watersheds are defined here as VCUs.
[2] Intact is defined here as having less than 5 percent of original POG harvested and not containing other major disturbances.
[3] Considers past and future harvest on private and other non-NFS lands.

Alternative 2

Alternative 2 would rank second lowest in terms of effects on biodiversity primarily because it would result in the second lowest POG harvest and the second highest POG acreage in reserves. Although this alternative was not specifically evaluated in the 1996 panel assessment, based on its level of harvest and other factors considered in the assessment, it is clear that the assessment would have confirmed this ranking.

Under Alternative 2, approximately 84 percent of all existing POG would be maintained within reserves. Standards and guidelines would protect an additional 11 percent of the existing POG from harvest and the maximum POG potentially harvested would be approximately 215,000 acres or 4 percent (Table 3.9-12). Long-term maximum harvest of high-volume and large-tree POG are projected to be in the 4 to 5 percent range. In addition, there would be about 286,000 acres of existing productive young growth that would not be harvested and that would eventually develop into mature forest and then POG (Table 3.9-13). This represents a long-term replacement for over 100 percent of the future maximum POG harvest.

Assuming maximum harvest over 100+ years, approximately 88 percent of the original POG would remain Forest-wide; 77 percent of the original POG would be in reserves (Table 3.9-14). Harvest would be spread over 18 out of 21 provinces occupied by the Tongass, but only 8 provinces would have potential harvest exceeding 5,000 acres. At least 12 of the 21 provinces would have 90 percent or more of their original POG remaining after 100+ years, and only 2 provinces (North Central Prince of Wales and Etolin & Vicinity) would have less than 75 percent remaining (Table 3.9-14).

Relative to the largest tree categories, after 100+ years of maximum implementation of Alternative 2, 83 percent of the original high-volume POG and 75 percent of the original large-tree POG would remain, with the vast majority of these acres in reserves (Tables 3.9-15 and 3.9-16). At least 11 of the provinces would maintain 90 percent or more of their original high-volume POG and 4 provinces would maintain less than 75 percent (minimum = 58 percent for North Central Prince of Wales) (Table 3.9-15). Relative to large-tree POG, at least 9 provinces would maintain 90 percent or more of their original acres and 9 provinces would have less than 75 percent (minimum = 32 percent for East Baranof) (Table 3.9-16).

Implementation of Alternative 2 would result in a maximum reduction of the karst POG on the Tongass from 69 percent of the original karst POG at present, to 63 percent after 100+ years. Low elevation karst POG would be reduced from 62 percent currently, to 56 percent (Table 3.9-17).

Long-term POG representation by ecological subsection would be maintained under Alternative 2 by protecting at least 50 percent of original POG in all 73 subsections (Table 3.9-18). At least 90 percent of original POG would be maintained in 43 of the 73 subsections and at least 75 percent would be maintained in 66 out of the 73 subsections.

If one considers the regrowth of current young growth that would be protected under this alternative (Table 3.9-13), after 100+ years the equivalent of an additional 5 percent of the original POG acres would be in mature forest stands and some stands would be at the beginning stages of exhibiting older forest characteristics (Table 3.9-14). Similarly, an additional 8 percent of the original high-volume POG, 12 percent of the original large-tree POG, and 17 percent of the original karst POG would be in mature forest stages (Tables 3.9-15, 3.9-16, and 3.9-17, respectively). In summary, after 100+ years of implementation under Alternative 2, 93 percent of the original POG would be remaining as POG or in mature forest stages. Likewise, 91 percent of the original high-volume POG would still be in high-volume POG or in mature forest stages, 87 percent of the original large-tree POG would be remaining as large-tree POG or in mature forest stages, and 80 percent of the original karst POG would be remaining as POG or in mature forest stages.

Alternative 2 would result in the additional conversion of intact large watersheds to a modified condition. After 100+ years of implementation under maximum harvest, the percentage of intact watersheds would be reduced from 69 percent to 59 percent of the Tongass. Similarly, the percentage of the land area of the Tongass in intact watersheds would be reduced from 74 percent to 67 percent (Table 3.9-19). However, the majority of this reduction would occur as a result of additional development on non-NFS lands, even if no additional Tongass harvest occurred. Approximately 8 percentage points of the drop in percentage of intact watersheds and 5 percentage points of the drop in acreage are due to additional development on non-NFS lands.

Alternative 3

Alternative 3 would rank third lowest in terms of effects on biodiversity primarily because it would result in the third lowest POG harvest and the third highest POG acreage in reserves. Although this alternative was not specifically evaluated in the 1996 panel assessment, based on its level of harvest and other factors considered in the assessment, it is clear that the assessment would have confirmed this ranking.

Alternative 3 would maintain approximately 78 percent of all existing POG would be maintained within reserves. Standards and guidelines would protect an additional 16 percent of the existing POG from harvest and the maximum POG potentially harvested would be approximately 313,000 acres or 6 percent (Table 3.9-12). Long-term maximum harvest of high-volume and large-tree POG are projected to be in the 7 to 8 percent range. In addition, there would be about 270,000 acres of existing productive young growth that would not be harvested and that would eventually develop into mature forest and then POG (Table 3.9-13). This represents a long-term replacement for over 86 percent of the future maximum POG harvest.

Assuming maximum harvest over 100+ years, approximately 86 percent of the original POG would remain Forest-wide; 72 percent of the original POG would be in reserves (Table 3.9-14). Harvest would be spread over 18 out of 21 provinces occupied by the Tongass, but only 12 provinces would have potential harvest exceeding 5,000 acres. At least 11 of the 21 provinces would have 90 percent or more of their original POG remaining after 100+ years, and only 2 provinces (North Central Prince of Wales and Etolin & Vicinity) would have less than 75 percent remaining (Table 3.9-14).

Relative to the largest tree categories, after 100+ years of maximum implementation of Alternative 3, 81 percent of the original high-volume POG and 73 percent of the original large-tree POG would remain, with the vast majority of these acres in reserves (Tables 3.9-15 and 3.9-16). At least 9 of the provinces would maintain 90 percent or more of their original high-volume POG and 5 provinces would maintain less than 75 percent (minimum = 56 percent for North Central Prince of Wales) (Table 3.9-15). Relative to large-tree POG, at least 7 provinces would maintain 90 percent or more of their original acres and 9 provinces would have less than 75 percent (minimum = 32 percent for East Baranof) (Table 3.9-16).

Implementation of Alternative 3 would result in a maximum reduction of the karst POG on the Tongass from 69 percent of the original karst POG at present, to 62 percent after 100+ years. Low elevation karst POG would be reduced from 62 percent currently, to 55 percent (Table 3.9-17).

Long-term POG representation by ecological subsection would be maintained under Alternative 3 by protecting at least 49 percent of original POG in all 73 subsections (Table 3.9-18). At least 90 percent of original POG would be maintained in 41 of the 73 subsections and at least 75 percent would be maintained in 62 out of the 73 subsections. The one subsection with less than 50 percent of its original POG, North POW-Kuiu Carbonates, would still maintain about 94,000 acres of POG.

If one considers the regrowth of current young growth that would be protected under this alternative (Table 3.9-13), after 100+ years the equivalent of an additional 5 percent of the original POG acres would be in mature forest stands and some stands would be at the beginning stages of exhibiting older forest characteristics (Table 3.9-14). Similarly, an additional 8 percent of the original high-volume POG, 12 percent of the original large-tree POG, and 16 percent of the original karst POG would be in mature forest stages (Tables 3.9-15, 3.9-16, and 3.9-17, respectively). In summary, after 100+ years of implementation under Alternative 2, 91 percent of the original POG would be remaining as POG or in mature forest stages. Likewise, 89 percent of the original high-volume POG would still be in high-volume POG or in mature forest stages, 85 percent of the original large-tree POG would be remaining as large-tree POG or in mature forest stages, and 78 percent of the original karst POG would be remaining as POG or in mature forest stages.

Alternative 3 would result in the additional conversion of intact large watersheds to a modified condition. After 100+ years of implementation under maximum harvest, the percentage of intact watersheds would be reduced from 69 percent to 56 percent of the Tongass. Similarly, the percentage of the land area of the Tongass in intact watersheds would be reduced from 74 percent to 65 percent (Table 3.9-19). However, the majority of this reduction would occur as a result of additional development on non-NFS lands, even if no additional Tongass harvest occurred. Approximately 8 percentage points of the drop in percentage of intact watersheds and 5 percentage points of the drop in acreage are due to additional development on non-NFS lands.

Alternative 4

With several important exceptions, Alternative 4 is similar to most aspects of the current Forest Plan (Alternative 5). Most importantly, however, it would have fewer old-growth reserves. The Old-Growth Habitat LUD is used in only four provinces (plus a few individual reserves), but other non-development LUDs provide some reserves in all provinces. It also includes additional requirements of maintaining 33 percent of the old growth in each VCU and not harvesting more than 50 percent of the POG within a 50-year period. However, there is no requirement to consider spacing, location, size, shape, or composition in the design of the retained acres; as a result, Alternative 4 would not provide as much protection to the conservation of biodiversity if the retained acres are widely distributed, in small parcels, linear in shape, or do not protect important habitat features (e.g., important deer winter range, under-represented forest plant associations, or suspected goshawk nesting habitat). Alternative 4 would have the same beach and estuary fringe and riparian buffers as Alternative 5 that would enhance connectivity within the matrix, but would not include the goshawk and marten or the legacy forest structure standards and guidelines that require retention trees in harvest units within specific VCUs.

Alternative 4 is based on, and is similar to, the 1997 Alternative 6, which was evaluated in the 1997 Forest Plan Revision FEIS (see Chapter 2); therefore, the conclusions of the 1997 old-growth panel assessment can be extended to the current Alternative 4. The panel assessment concluded that this alternative was ranked in the middle group of the alternatives evaluated by the panel. As such, it ranked better than our 2007 Alternative 7 but, through comparisons with acreage harvested and other alternative components, it would have ranked worse than all of the other 2007 alternatives in terms of effects on biodiversity. In addition to the acres of harvest, the primary factor associated with this ranking is the absence of reserves over relatively large areas of the Tongass. The old-growth network was specifically designed to ensure the maintenance of well-distributed viable populations of all old-growth associated wildlife species across the Tongass. The 1996 panel assessment concluded that alternatives that did not emphasize the old-growth reserve network had the highest potentials to create biodiversity concerns within biogeographic provinces over the long term.

Moreover, the old-growth network was specifically designed to ensure the maintenance of well-distributed viable populations of all old-growth associated wildlife species across the Tongass. The 1997 FEIS panel assessment concluded that alternatives that did not include the OGR system have the highest potentials to create biodiversity concerns within biogeographic provinces over the long term. Therefore, by default, the reduction of this component of the conservation strategy under Alternative 4 would be expected to result in a greater loss of biodiversity relative to the current Forest Plan. This is particularly relevant in the Etolin and Revilla Island/Cleveland Peninsula biogeographic provinces where a substantial amount of timber harvest is proposed but where no reserve system or a very limited reserve system would be in place, respectively.

Alternative 4 would include 60 percent of the existing POG within reserves and an additional 27 percent would be protected within the matrix by standards and guidelines or not scheduled for harvest. As a result, about 13 percent, or 656,000 acres, would be subject to harvest (Table 3.9-12). Long-term maximum harvest of existing high-volume and large-tree POG are projected to be in the 15 to 16 percent range. In addition, there would be about 243,000 acres of existing productive young growth that would not be harvested and that would eventually develop into mature forest and then POG (Table 3.9-13). This represents a long-term replacement for about 37 percent of the future maximum POG harvest.

Assuming maximum harvest over 100+ years, approximately 79 percent of the original POG would remain Forest-wide; 55 percent of the original POG would be in reserves (Table 3.9-14). Harvest would be spread over 20 out of the 21 provinces, and 15 provinces would have potential harvest exceeding 5,000 acres. At least 7 of the 21 provinces would have more than 90 percent of their original POG remaining after 100+ years, and 5 provinces (North Central Prince of Wales, Kupreanof/Mitkof, Etolin & Vicinity, Kuiu, and East Baranof) would have less than 75 percent remaining (Table 3.9-14).

Relative to the largest tree categories, after 100+ years of maximum implementation of Alternative 4, 75 percent of the original high-volume POG and 68 percent of the original large-tree POG would remain, with the majority of these acres in reserves (Tables 3.9-15 and 3.9-16). At least 7 provinces would maintain 90 percent or more of their original high-volume POG and 9 provinces would maintain less than 75 percent (minimum = 51 percent for North Central Prince of Wales) (Table 3.9-15). Relative to large-tree POG, at least 5 provinces would maintain 90 percent or more of their original acres and 10 provinces would have less than 75 percent (minimum = 31 percent for East Baranof) (Table 3.9-16).

Implementation of Alternative 4 would result in a maximum reduction of the karst POG on the Tongass from 69 percent of the original karst POG at present, to 58 percent after 100+ years. Low elevation karst POG would be reduced from 62 percent currently, to 52 percent (Table 3.9-17).

Long-term POG representation by ecological subsection would be maintained under Alternative 4 by protecting at least 45 percent of original POG in all 73 subsections

(Table 3.9-18). At least 90 percent of original POG would be maintained in 29 of the 73 subsections and at least 75 percent would be maintained in 51 out of the 73 subsections. Two subsections, North POW-Kuiu Carbonates and Thomas Bay Outwash Plains, would have with less than 50 percent of their original POG remaining after 100+ years. North POW-Kuiu Carbonates would maintain about 86,000 acres of POG and Thomas Bay Outwash Plains would maintain about 7,000 acres of POG.

If one considers the regrowth of current young growth that would be protected under this alternative (Table 3.9-13), after 100+ years the equivalent of an additional 4 percent of the original POG acres would be in mature forest stands and some stands would be at the beginning stages of exhibiting older forest characteristics (Table 3.9-14). Similarly, an additional 7 percent of the original high-volume POG, 11 percent of the original large-tree POG, and 14 percent of the original karst POG would be in mature forest stages (Tables 3.9-15, 3.9-16, and 3.9-17, respectively). In summary, after 100+ years of implementation under Alternative 4, 83 percent of the original POG would be remaining as POG or in mature forest stages. Likewise, 82 percent of the original high-volume POG would still be in high-volume POG or in mature forest stages, 79 percent of the original large-tree POG would be remaining as large-tree POG or in mature forest stages, and 72 percent of the original karst POG would be remaining as POG or in mature forest stages.

Alternative 4 would result in the additional conversion of intact large watersheds to a modified condition. After 100+ years of implementation under maximum harvest, the percentage of intact watersheds would be reduced from 69 percent to 48 percent of the Tongass. Similarly, the percentage of the land area of the Tongass in intact watersheds would be reduced from 74 percent to 58 percent (Table 3.9-19). However, a portion of this reduction would occur as a result of additional development on non-NFS lands, even if no additional Tongass harvest occurred. Approximately 8 percentage points of the drop in percentage of intact watersheds and 5 percentage points of the drop in acreage are due to additional development on non-NFS lands.

Alternative 5

Alternative 5 represents the current Forest Plan. Although this alternative was not specifically evaluated in the 1996 panel assessment, based on its level of harvest and other factors considered in the assessment, it is clear that it would rate as having a lower effect on biodiversity than Alternatives 4 and 7 and a higher effect than Alternatives 1, 2, 3, or 6.

Alternative 5 would maintain 71 percent of the existing POG within reserves and an additional 20 percent would be protected within the matrix by standards and guidelines or not scheduled for harvest. As a result, about 9 percent, or 463,000 acres, would be subject to harvest (Table 3.9-12). Long-term maximum harvest of high-volume and large-tree POG are projected to be in the 10 to 11 percent range. In addition, there would be about 250,000 acres of existing productive young growth that would not be harvested and that would eventually develop into mature forest and then POG (Table 3.9-13). This represents a long-term replacement for about 54 percent of the future maximum POG harvest.

Assuming maximum harvest over 100+ years, approximately 83 percent of the original POG would remain Forest-wide; 65 percent of the original POG would be in reserves (Table 3.9-14). Harvest would be spread over 19 out of the 21 provinces, but only 14 provinces would have potential harvest exceeding 5,000 acres. At least 8 of the 21 provinces would have more than 90 percent of their original POG remaining after 100+ years, and 3 provinces (North Central Prince of Wales, Kupreanof/Mitkof, and Etolin & Vicinity) would have less than 75 percent remaining (Table 3.9-14).

Relative to the largest tree categories, after 100+ years of maximum implementation of Alternative 5, 79 percent of the original high-volume POG and 71 percent of the original large-tree POG would remain, with the majority of these acres in reserves (Tables 3.9-15 and 3.9-16). At least 8 provinces would maintain 90 percent or more of their original high-volume POG and 5 provinces would maintain less than 75 percent (minimum = 55 percent for North Central Prince of Wales) (Table 3.9-15). Relative to large-tree POG, at least 5 provinces would maintain 90 percent or more of their original acres and 9 provinces would have less than 75 percent (minimum = 31 percent for East Baranof) (Table 3.9-16).

Implementation of Alternative 5 would result in a maximum reduction of the karst POG on the Tongass from 69 percent of the original karst POG at present, to 60 percent after 100+ years. Low elevation karst POG would be reduced from 62 percent currently, to 54 percent (Table 3.9-17).

Long-term POG representation by ecological subsection would be maintained under Alternative 5 by protecting at least 48 percent of original POG in all 73 subsections (Table 3.9-18). At least 90 percent of original POG would be maintained in 31 of the 73 subsections and at least 75 percent would be maintained in 56 out of the 73 subsections. One subsection, North POW-Kuiu Carbonates, would have with less than 50 percent of its original POG remaining after 100+ years, but would still maintain about 91,000 acres.

If one considers the regrowth of current young growth that would be protected under this alternative (Table 3.9-13), after 100+ years the equivalent of an additional 5 percent of the original POG acres would be in mature forest stands and some stands would be at the beginning stages of exhibiting older forest characteristics (Table 3.9-14). Similarly, an additional 7 percent of the original high-volume POG, 11 percent of the original large-tree POG, and 14 percent of the original karst POG would be in mature forest stages (Tables 3.9-15, 3.9-16, and 3.9-17, respectively). In summary, after 100+ years of implementation under Alternative 5, 88 percent of the original POG would be remaining as POG or in mature forest stages. Likewise, 86 percent of the original high-volume POG would still be in high-volume POG or in mature forest stages, 82 percent of the original large-tree POG would be remaining as large-tree POG or in mature forest stages, and 74 percent of the original karst POG would be remaining as POG or in mature forest stages.

Alternative 5 would result in the additional conversion of intact large watersheds to a modified condition. After 100+ years of implementation under maximum harvest, the percentage of intact watersheds would be reduced from 69 percent to 50 percent of the Tongass. Similarly, the percentage of the land area of the Tongass in intact watersheds would be reduced from 74 percent to 60 percent (Table 3.9-19). However, over on-third of this reduction would occur as a result of additional development on non-NFS lands, even if no additional Tongass harvest occurred. Approximately 8 percent of the drop in percentage of intact watersheds and 5 percent of the drop in acreage is due to additional development on non-NFS lands. Approximately 8 percentage points of the drop in percentage of intact watersheds and 5 percentage points of the drop in acreage are due to additional development on non-NFS lands.

Alternative 6

Alternative 6 represents the proposed action and represents a modification of the current Forest Plan. It would result in slightly less POG retained within the matrix, but would expand the reserve system relative to the current Forest Plan

(Alternative 5). On balance, it would protect more POG than Alternative 5, particularly the POG in reserves and large-tree POG. Therefore, it would have a lower overall effect on biodiversity than Alternative 5. Although this alternative was not specifically evaluated in the 1996 panel assessment, based on its level of harvest and other factors considered in the assessment, it is clear that it would have a lower effect on biodiversity than Alternatives 4, 5, and 7 and a higher effect than Alternatives 1, 2, or 3.

Under Alternative 6, 72 percent of the existing POG would be included within reserves and an additional 19 percent would be protected within the matrix by standards and guidelines or not scheduled for harvest. As a result, about 9 percent, or 445,000 acres, would be subject to harvest (Table 3.9-12). Although Alternative 6 would protect 28,000 fewer acres of POG in the matrix than Alternative 5 (partly because the matrix land area would be smaller under Alternative 6), it would have 45,000 more acres of POG in reserves. Long-term maximum harvest of high-volume and large-tree POG are projected to be in the 10 to 11 percent range. Again in comparison with Alternative 5, although Alternative 6 would protect 1,000 fewer acres of large-tree POG in the matrix, it would maintain about 11,000 more acres within reserves. Alternative 6 includes a refinement of small old-growth reserve boundaries relative to Alternative 5; one of the factors this refinement emphasized was the incorporation of more large-tree POG.

In addition to the POG that would not be harvested, there would be about 255,000 acres of existing productive young growth that would not be harvested under Alternative 6 and that would eventually develop into mature forest and then POG (Table 3.9-13). This represents a long-term replacement for about 57 percent of the future maximum POG harvest.

Assuming maximum harvest over 100+ years, approximately 83 percent of the original POG would remain Forest-wide; 66 percent of the original POG would be in reserves (Table 3.9-14). Harvest would be spread over 19 out of the 21 provinces, but only 13 provinces would have potential harvest exceeding 5,000 acres. At least 8 of the 21 provinces would have more than 90 percent of their original POG remaining after 100+ years, and 3 provinces (North Central Prince of Wales, Kupreanof/Mitkof, and Etolin & Vicinity) would have less than 75 percent remaining (Table 3.9-14).

Relative to the largest tree categories, after 100+ years of maximum implementation of Alternative 6, 79 percent of the original high-volume POG and 72 percent of the original large-tree POG would remain, with the majority of these acres in reserves (Tables 3.9-15 and 3.9-16). At least 8 provinces would maintain 90 percent or more of their original high-volume POG and 5 provinces would maintain less than 75 percent (minimum = 54 percent for North Central Prince of Wales) (Table 3.9-15). Relative to large-tree POG, at least 6 provinces would maintain 90 percent or more of their original acres and 9 provinces would have less than 75 percent (minimum = 31 percent for East Baranof) (Table 3.9-16).

Implementation of Alternative 6 would result in a maximum reduction of the karst POG on the Tongass from 69 percent of the original karst POG at present, to 61 percent after 100+ years. Low elevation karst POG would be reduced from 62 percent currently, to 55 percent (Table 3.9-17).

Long-term POG representation by ecological subsection would be maintained under Alternative 6 by protecting at least 48 percent of original POG in all 73 subsections (Table 3.9-18). At least 90 percent of original POG would be maintained in 31 of the 73 subsections and at least 75 percent would be maintained in 57 out of the 73 subsections. One subsection, North POW-Kuiu Carbonates, would have with less than 50 percent of its original POG remaining after 100+ years, but would still maintain about 92,000 acres.

If one considers the regrowth of current young growth that would be protected under this alternative (Table 3.9-13), after 100+ years the equivalent of an additional 5 percent of the original POG acres would be in mature forest stands and some stands would be at the beginning stages of exhibiting older forest characteristics (Table 3.9-14). Similarly, an additional 7 percent of the original high-volume POG, 11 percent of the original large-tree POG, and 15 percent of the original karst POG would be in mature forest stages (Tables 3.9-15, 3.9-16, and 3.9-17, respectively). In summary, after 100+ years of implementation under Alternative 6, 88 percent of the original POG would be remaining as POG or in mature forest stages. Likewise, 86 percent of the original high-volume POG would still be in high-volume POG or in mature forest stages, 83 percent of the original large-tree POG would be remaining as large-tree POG or in mature forest stages, and 76 percent of the original karst POG would be remaining as POG or in mature forest stages.

Alternative 6 would result in the additional conversion of intact large watersheds to a modified condition. After 100+ years of implementation under maximum harvest, the percentage of intact watersheds would be reduced from 69 percent to 51 percent of the Tongass. Similarly, the percentage of the land area of the Tongass in intact watersheds would be reduced from 74 percent to 60 percent (Table 3.9-19). However, over on-third of this reduction would occur as a result of additional development on non-NFS lands, even if no additional Tongass harvest occurred. Approximately 8 percentage points of the drop in percentage of intact watersheds and 5 percentage points of the drop in acreage are due to additional development on non-NFS lands.

Alternative 7

Alternative 7 represents the alternative with the highest POG harvest level. It also differs from the other alternatives in that it does not designate Old-Growth Habitat LUDs, although it does include reserves associated with other non-development LUDs. In addition to the elimination of Old-Growth Habitat LUDs, Alternative 7 also proposes to reduce the beach buffer from 1,000 feet to 500 feet. This would likely reduce the effectiveness of these shoreline corridors in providing landscape linkages between habitat reserves and thus, potentially reduce the interconnectedness of the old-growth forest ecosystem. Further, it differs from all other alternatives by not requiring riparian buffers along Class III streams, which would also have some negative effect on old-growth connectivity (although Class I and II riparian buffers are most important in this regard). Finally, as in the case for Alternative 4, it would not include the goshawk and marten or the legacy forest structure standards and guidelines that require retention trees in harvest units within specific VCUs.

Alternative 7 is based on and is similar to the 1997 Alternative 2, which was evaluated in the 1997 Forest Plan Revision FEIS (see Chapter 2); therefore, the conclusions of the 1997 old-growth panel assessment can be extended to the current Alternative 7. The panel assessment concluded that this alternative was ranked in the highest risk group in terms of effects on biodiversity among the alternatives evaluated by the panel. As such, it ranked worse than our 2007 Alternative 4 and, through comparisons with acreage harvested and other alternative components, it would have ranked worse than all of the other 2007 alternatives as well. In addition to the acres of harvest, the primary factor associated with this ranking is the absence of reserves over many relatively large areas of the Tongass. Of particular concern are the North Central Prince of Wales Island, Etolin Island & Vicinity, Kupreanof/Mitkof Island, and Revilla Island/Cleveland

Peninsula biogeographic provinces, which have already been heavily affected by timber harvest. The old-growth network was specifically designed to ensure the maintenance of well-distributed viable populations of all old-growth associated wildlife species across the Tongass. The 1996 panel assessment concluded that alternatives that did not emphasize the old-growth reserve network had the highest potentials to create biodiversity concerns within biogeographic provinces over the long term.

Alternative 7 would include 57 percent of the existing POG within reserves and an additional 27 percent would be protected within the matrix by standards and guidelines or not scheduled for harvest. As a result, about 16 percent, or 807,000 acres, would be subject to harvest (Table 3.9-12). Long-term maximum harvest of existing high-volume and large-tree POG are projected to be in the 18 to 20 percent range. In addition, there would be about 219,000 acres of existing productive young growth that would not be harvested and that would eventually develop into mature forest and then POG (Table 3.9-13). This represents a long-term replacement for about 27 percent of the future maximum POG harvest.

Assuming maximum harvest over 100+ years, approximately 77 percent of the original POG would remain Forest-wide; 52 percent of the original POG would be in reserves (Table 3.9-14). Harvest would be spread over 20 out of the 21 provinces, and 16 provinces would have potential harvest exceeding 5,000 acres. At least 7 of the 21 provinces would have at least 90 percent of their original POG remaining after 100+ years, and 7 provinces (North Central Prince of Wales, Kupreanof/Mitkof, Etolin & Vicinity, Revilla/Cleveland, Kuiu, East Chichagof, and East Baranof) would have less than 75 percent remaining (Table 3.9-14).

Relative to the largest tree categories, after 100+ years of maximum implementation of Alternative 7, 72 percent of the original high-volume POG and 64 percent of the original large-tree POG would remain, with the majority of these acres in reserves (Tables 3.9-15 and 3.9-16). At least 7 provinces would maintain 90 percent or more of their original high-volume POG and 11 provinces would maintain less than 75 percent (minimum = 44 percent for North Central Prince of Wales) (Table 3.9-15). Relative to large-tree POG, at least 5 provinces would maintain 90 percent or more of their original acres and 12 provinces would have less than 75 percent (minimum = 31 percent for East Baranof) (Table 3.9-16).

Implementation of Alternative 7 would result in a maximum reduction of the karst POG on the Tongass from 69 percent of the original karst POG at present, to 54 percent after 100+ years. Low elevation karst POG would be reduced from 62 percent currently, to 47 percent (Table 3.9-17).

Long-term POG representation by ecological subsection would be maintained under Alternative 7 by protecting at least 41 percent of original POG in all 73 subsections (Table 3.9-18). At least 90 percent of original POG would be maintained in 25 of the 73 subsections and at least 75 percent would be maintained in 45 out of the 73 subsections. Four subsections, North POW-Kuiu Carbonates, Central POW Volcanics, Stikine Strait Complex, and Thomas Bay Outwash Plains, would have with less than 50 percent of their original POG remaining after 100+ years. These subsections would have 78,000, 79,000, 16,000, and 6,000 acres of POG, respectively.

If one considers the regrowth of current young growth that would be protected under this alternative (Table 3.9-13), after 100+ years the equivalent of an additional 4 percent of the original POG acres would be in mature forest stands and some stands would be at the beginning stages of exhibiting older forest characteristics (Table 3.9-14). Similarly, an additional 6 percent of the original high-volume POG, 9 percent of the original large-tree POG, and 12 percent of the original karst POG would be in mature forest stages (Tables 3.9-15, 3.9-16, and 3.9-17, respectively). In summary, after 100+ years of implementation under Alternative 7, 81 percent of the original POG would be remaining as POG or in mature forest stages. Likewise, 78 percent of the original high-volume POG would still be in high-volume POG or in mature forest stages, 71 percent of the original large-tree POG would be remaining as large-tree POG or in mature forest stages, and 66 percent of the original karst POG would be remaining as POG or in mature forest stages.

Alternative 7 would result in the additional conversion of intact large watersheds to a modified condition. After 100+ years of implementation under maximum harvest, the percentage of intact watersheds would be reduced from 69 percent to 47 percent of the Tongass. Similarly, the percentage of the land area of the Tongass in intact watersheds would be reduced from 74 percent to 57 percent (Table 3.9-19). However, a portion of this reduction would occur as a result of additional development on non-NFS lands, even if no additional Tongass harvest occurred. Approximately 8 percentage points of the drop in percentage of intact watersheds and 5 percentage points of the drop in acreage are due to additional development on non-NFS lands.

Endemics

As noted in the Endemism subsection of the Affected Environment part of this section, Southeast Alaska is rich in endemics, and endemic mammals and other groups are sensitive to future landscape disturbances. Because unproductive forest and non-forested ecosystems have not changed appreciably since original levels, nor are they anticipated to change under the full implementation of the Forest Plan under any of the alternatives, concerns focus on the loss of POG habitat, which is most influenced by management activities. Those species most closely associated with old growth are assumed to be at greatest risk.

The 1997 Forest Plan FEIS panel assessment for endemics evaluated 14 species or subspecies endemic to Southeast Alaska (see the *Wildlife* section of the 1997 Forest Plan Revision FEIS and the *Wildlife* section in this chapter for additional information). Each of the above species occupies restricted ranges (i.e., currently known to be limited to one or a few isolated islands). Under all alternatives, the Prince of Wales flying squirrel is currently assumed to have the greatest viability concern over time.

The panel concluded that the 1997 Alternative 11 (equivalent to the current Forest Plan or the 2007 Alternative 5) ranked among the alternatives with the highest likelihood of sustaining habitat to support viable populations of endemic mammals. Under the current Forest Plan, all islands less than 1,000 acres were removed from the timber base to eliminate risk to these species associated with habitat loss or alteration from timber harvest. The 1,000-foot beach buffer, riparian corridors, and the old-growth reserve system are also features of the current Forest Plan that provide functional habitat for species with relatively small home ranges. These protective provisions would be maintained under all the action alternatives, with the exception of Alternative 7 under which the beach fringe buffer would be reduced to 500 feet, the system of old-growth reserves would be significantly contracted, and Class III stream buffers would be eliminated. Alternative 4 would also significantly reduce the old-growth reserve system in some provinces. Alternatives 1, 2, 3, and 6, which propose to harvest less timber than under the current Forest Plan, would likely continue to maintain habitat and connectivity to support viable populations of endemic mammals.

Based on the number of acres converted from the matrix to reserves, as described above, the ability to maintain viable populations of endemic mammals would be greatest under Alternative 1, followed by Alternatives 2, 3, 6, 5, 4, and 7. See the *Wildlife* section in this chapter for additional species-specific discussion.

Invasive Species

As discussed in the Affected Environment section, numerous non-native species have been introduced or transplanted in Alaska, including plants, wildlife, fish, other aquatic organisms, and insects. Managing invasive species on the Tongass National Forest must include increased public awareness at all levels coupled with interagency cooperation and development of cooperative management partnerships to monitor and limit invasive species populations at current levels in Alaska.

Currently, non-native or invasive plant species make up the vast majority of species listed as threats in Alaska. Fifteen of the species found on the Tongass are among the species that pose a greater potential threat. The areas of greatest non-native plant diversity and extent of invasion have been found around towns and the most heavily traveled areas. The areas with the lowest number of species were further from population centers or paved roads (Arhangelsky 2005). Schrader and Hennon (2005) cited several references that suggest that the highest invasive plant occurrences are in areas of disturbance such as roads, recreational areas, commercial, and industrial development. As more surveys are conducted, it is anticipated that more invasive plant species will be documented (see the Plant section in this chapter for additional discussion of effects from non-native plants).

Non-native wildlife species have been transplanted for sport hunting or other consumption opportunities such as trapping or, in some cases, accidentally introduced in Southeast Alaska; however, only the Norway rat is considered invasive at this time. Concern regarding potential range expansion of this species exists; however, measures to reduce the potential of introducing this species elsewhere on the Tongass is limited because the Forest does not have jurisdiction regarding shipping throughout Southeast Alaska waters. Because of the growing number of elk in Southeast Alaska, this species may be considered as a possible invasive species outside of Etolin and Zarembo islands, due to their effects on Sitka black-tailed deer, which have similar habitat needs (see the *Wildlife* section in this chapter).

Invasive fish and other aquatic organisms identified as threats for Alaska are discussed in more detail under the *Fish* section in this chapter. Established populations (throughout the Susitna River drainage, parts of the Kenai system) of northern pike (with the exception of Pike Lakes on the Yakutat Ranger District) pose the greatest immediate concern, while the Atlantic salmon, Chinese mitten crab, and New Zealand mudsnail are species likely to invade Alaska in coming years (Schrader and Hennon 2005). Effects of these species on native populations are currently unknown; however, based on documented impacts in other areas, species such as the Chinese mitten crab and New Zealand mudsnail quickly colonize environments and dominate the invertebrate community in aquatic ecosystems by consuming large portions of the food resources, outcompeting and physically crowding native species. This could lead to local extirpation in some areas over time.

Schrader and Hennon (2005) noted that invasive tree pathogens are not currently damaging Alaskan ecosystems, but there are numerous species that could cause widespread tree mortality if introduced. Introduced insects currently established in Alaska include the larch sawfly, alder woolly aphid, spruce aphid, and amber-marked birch leafminer, and could cause widespread tree defoliation and mortality (see the *Forest Health* section in this chapter for additional discussion of effects).

With the exception of certain fish and aquatic organisms that would not be expected to increase independent of any of the alternatives, most of the other invasive or potentially invasive species listed above would be influenced by management activities that would increase harvest and other associated management activities, such as the building of new roads. Alternatives 1, 2, and 3 designate more reserve areas than the other alternatives. Under Alternatives 4 and 7, there would be an increase in the amount of harvest and roading, relative to the current Forest Plan; more lands would be available for timber harvest activities under Alternatives 4 and 7. Although any management activity has the potential to increase the risk of introducing invasive species to a system, it is reasonable to assume that increases in harvest and roading from current levels would contribute additional source areas for invasive establishment and persistence.

None of the alternatives proposes changes to the management framework of the Tongass in relation to invasives. Most of the species identified above are not specifically addressed under the Forest Plan Monitoring section or standards and guidelines; however, the Alaska Region of the Forest Service is currently developing an invasive species strategy that will apply the principles of prevention, early detection, control, and rehabilitation in cooperation with various agencies and partners to reduce or eliminate invasive species establishment.

Cumulative Effects

When considering biodiversity and the distribution of old growth across the Tongass, it is important to consider non-NFS lands (which include private, city, state, and other federal lands. As noted in the subsections titled *Cumulative Past Harvest* and *Current Conditions by Biogeographic Province* in the *Affected Environment* portion of this section, past harvest has been more extensive on non-NFS lands than on NFS lands. The area used to assess cumulative effects on biodiversity encompasses all lands in Southeast Alaska, including all lands within the Tongass National Forest boundary, from the Yakutat area southeast to the south of Ketchikan. In addition, it includes the area of Glacier Bay National Park, and the areas around Haines and Skagway. Some resource areas may require larger or smaller areas to address cumulative effects. For example, for some resources, the extent of analysis needs only include the area within the Tongass boundary (i.e., without the Glacier Bay National Park and Haines/Skagway areas). In particular, cumulative effects are sometimes addressed within a VCU (e.g., water, fish, wetlands), or a WAA (e.g., wolves, deer), or a Biogeographic Province or an Ecological Subsection (e.g., species viability).

Under the current Forest Plan, with few exceptions (e.g., minerals production and utility corridors), only lands classified as suitable for timber production are scheduled for harvest in the future. However, other reasonably foreseeable activities that have the potential to cumulatively affect biodiversity locally and regionally include:

- Minerals extraction (e.g., Green's Creek on Admiralty Island and Kensington Gold Mine near Berners Bay north of Juneau),
- Transmission line intertie projects (e.g., Swan Lake-Lake Tyee Intertie northeast of Ketchikan),
- Hydroelectric projects (e.g., Four Dam Pool projects, other limited small hydroelectric projects such as Angoon),
- Regional transportation developments (e.g., Juneau Access Road),
- Growth in the cruise ship, guiding services, fishing/destination type lodging, and
- Human settlements (e.g., expansion of cities like Juneau and Ketchikan, recreational cabin development, and land auctions by the State of Alaska).

Because plant and wildlife populations exist across all land ownerships, addressing potential adverse effects of management activities on overall biodiversity requires agencies and other landowners to work together. A species population viability and its distribution within Southeast Alaska is influenced in part by geologic processes (e.g., island archipelago), habitat and connectivity between patches (e.g., fragmentation), and by state and federal regulatory mechanisms such as harvest limits, season length, subsistence needs, and timber harvest practices on all lands. Overall, biodiversity on the Tongass remains in good condition and are mostly dominated by old-growth forest. As development continues through timber harvest, associated activities such as road building, and community expansion, particularly in areas where extensive development has already occurred (i.e., Prince of Wales Island), maintaining connectivity and roadless refugia will become increasingly important, particularly for wide-ranging species whose distribution depends on some level of connectivity across the landscape. In addition, the management of human resources will continue to play a role in the viability and distribution of biodiversity across the Forest.

Cumulative Effects on Productive Old Growth in General

The focus of the analysis remains on changes to the old-growth ecosystem as this habitat is most affected under each of the alternatives. This section displays future projected harvest on both NFS lands and non-NFS lands by biogeographic province and ecological subsection. For assessing overall effects to biodiversity across all ownerships for Southeast Alaska, both biogeographic province and ecological subsection are appropriate scales. As stated in the *Affected Environment* section, using both biogeographic provinces and ecological subsection classifications allows additional insight into how various communities are represented at different landscape scales. Both classification systems were developed using different processes, but complement each other in terms of addressing biodiversity.

To estimate the future harvest of POG on non-NFS lands, it was assumed that 75 percent of the remaining old-growth would be harvested on Native corporation lands and 50 percent of the remaining old growth would be harvested on state lands, other private lands, and lands owned by municipalities, over the life of the Forest Plan (100+ years). The total percent harvest of POG on all lands within Southeast Alaska by biogeographic province and each ecological subsection could then be calculated.

On NFS lands, approximately 455,000 acres have been harvested. As a result, 92 percent of the original POG remains today. Additional POG harvest on NFS lands under the alternatives would range from an estimated maximum of 86,000 acres under Alternative 1 to 807,000 acres under Alternative 7, over the next 100+ years. The result would be that an estimated 90 to 77 percent of the original POG on these lands would remain indefinitely.

Approximately 371,000 acres of POG (including a small portion of helicopter partial harvest acres) have been harvested on non-NFS lands, with the majority of the harvest occurring in the last 25 years. With this harvest, 51 percent of the original POG is estimated to remain on these lands. Future harvest on non-NFS lands over the next 100+ years is estimated to be as high as 295,000 additional acres. Therefore, after the total cumulative harvest on non-NFS lands an estimated 19 percent is expected to remain (considered to be a conservatively high estimate).

Considering NFS and non-NFS lands combined, 87 percent of the area originally occupied by POG remains unharvested today. The percent of original POG that would remain after full implementation of the Forest Plan and future non-NFS harvest (after 100+ years) would range from 82 percent under Alternative 1 to 71 percent under Alternative 7 (Table 3.9-20). This does not include approximately 3 to

6 percent additional that would be represented by mature second growth that is protected from harvest, some of which would be beginning to take on older forest characteristics.

Past harvest activities have concentrated, and future harvest will continue to concentrate under most alternatives, primarily in three biogeographic provinces: the North Central Prince of Wales, Kupreanof/Mitkof, and Revilla/Cleveland provinces. These three provinces account for about 56 percent of the past harvest and will account for 44 to 74 percent of future harvest, depending on the alternative.

North Central Prince of Wales is the province with the most extensive past and future harvest and development. Currently, 65 percent of the original POG remains in the province (Table 3.9-20). After 100+ years, the minimum amount remaining would range from 44 to 55 percent, depending on the alternative.

In addition to the three provinces mentioned above, relatively high rates of POG removal have occurred, or are planned to occur, within the Etolin Island & Vicinity, East Chichagof, Southern Outer Island, Dall Island & Vicinity, and Yakutat Forelands biogeographic provinces (however, POG removal in the Yakutat Forelands province is partially due to windthrow rather than timber harvest). Under all alternatives, harvest will continue to be concentrated in matrix NFS lands and on private and state lands, and reserves will continue to exist on NFS, other federal, and some state lands. More specific descriptions of effects are presented under the *Cumulative Effects by Biogeographic Province* subsection below.

Theoretical and empirical studies suggest that the likelihood of a population persisting over time is related to some threshold level of habitat loss across the landscape (Fahrig 1997, 1999, 2003; Flather et al. 2002; Andren 1994). Reported threshold levels for the percentage of habitat maintained at which the rate of landscape extinction increases range from 20 percent (Fahrig 1997) to 50 percent (Soule and Sanjayan 1998), depending in part on the dispersal capability of the species under consideration (see the Cumulative Effects subsection of the *Wildlife* section for further information on this topic). It is important to note that, although many plant and animal species make higher use of the larger forest types defined by high-volume and large-tree POG, few are totally restricted to these habitats. In fact, almost all species make at least some use of types other than mapped POG (e.g., unproductive old growth and older young growth forests). The thresholds of importance to an individual species depend on specific habitat requirements as well as dispersal capabilities. Existing natural fragmentation of habitats can also affect the level of additional fragmentation that can be supported. Therefore, the percentages of POG and larger tree types presented in these cumulative effects discussions represent indices of risk, which can be generally compared with theoretical and empirical thresholds, recognizing the high degree of variability among species habitat requirements, dispersal capabilities, and the natural level of fragmentation within the landscape.

Within the Tongass National Forest boundary, the Conservation Strategy was designed to address the more extensive harvest on non-NFS lands through the old-growth reserve system network and Forest-wide standards and guidelines, both of which were intended to maintain habitat components important to a variety of species and maintain connectivity across the landscape, with or without much contribution from non-NFS lands. In other words, benefits from non-NFS lands were assumed to be minimal in the design of the strategy. Therefore, the cumulative effects associated with the combination of NFS and non-NFS harvest, for those alternatives that incorporate the complete conservation strategy (i.e., Alternatives 1, 2, 3, 5, and 6), are not expected to be appreciably different than the direct and indirect effects.

[1] Maximum Forest Plan implementation is defined as the maximum harvest allowed by the Allowable Sale Quantity each decade. The estimate assumes all scheduled suitable POG is harvested [calculated by subtracting alternative-specific reduction factors for the Model Implementation Reduction Factor (MIRF) and scheduling from the mapped suitable acreage under each alternative (see the Timber section)].
[2] Based on an inventory of existing harvest on non-NFS lands and the estimation of future harvest by major landowner category.

Cumulative Effects on Specific Productive Old-Growth Types

Historically, as discussed in the *Past Old-Growth Harvest* subsection, some of the more productive forest types have been harvested at a higher rate than POG in general. These forest types have included both high-volume and large-tree POG (SD67), POG on karstlands, and low elevation POG (Albert and Schoen 2007). Tables 3.9-21 and 3.9-22 present the acreage of original high-volume and large-tree POG along with the percent currently remaining and the percent remaining after 100+ years by biogeographic province for all of Southeast Alaska.

For all ownerships across Southeast Alaska, an estimated 82 percent of high-volume POG remains today, although the percentage found in individual provinces ranges from a low of 56 percent to a high of 100 percent. After 100+ years, it is estimated that the overall amount remaining would range from a high of 75 percent under Alternative 1 to a low of 65 percent under Alternative 7 (Table 3.9-21). This does not include approximately 5 to 9 percent additional that would be represented by mature second growth growing on high-volume sites and is protected from harvest. The percent of POG remaining would range from 45 to 100 percent in individual provinces under Alternative 1 and from 33 to 100 percent under Alternative 7.

Approximately 68 percent of large-tree POG remains on all ownerships combined in Southeast Alaska. The percent remaining in individual provinces ranges from a low of 33 percent to a high of 100 percent. After 100+ years, the amount remaining would range from a high of 62 percent under Alternative 1 to a low of 52 percent under Alternative 7 (Table 3.9-22). This does not include approximately 7 to 14 percent additional that would be represented by mature second growth growing on large-tree POG sites and is protected from harvest. The percent of POG remaining would range from 32 to 100 percent in individual provinces under Alternative 1 and from 30 to 100 percent under Alternative 7.

Cumulative harvest on karst lands has affected about 34 percent of all karst POG and resulted in approximately 66 percent of all karst POG remaining unharvested. This represents about 84 percent of all karst POG at moderate to higher elevations (> 800 ft.), but only about 60 percent of all karst POG at low elevations (< 800 ft.). After 100+ years and assuming that all karst POG on non-NFS lands is harvested, the overall percent remaining would range from a high of 60 percent under Alternative 1 to a low of 50 percent under Alternative 7. In addition, from 11 to 24 percent of the original karst POG would be in mature second growth, some of which would be beginning to take on older forest characteristics.

Cumulative Effects and Climate Change

In addition to the approach and direction of management on the Tongass, there is uncertainty with regards to the cumulative effects on biodiversity associated with climate change. Warmer temperatures and decreased precipitation are anticipated to result in changes to vegetation and thus the suitability of wildlife habitat, among other impacts (see *Climate and Air* section). Although some species may benefit (e.g., greater overwinter survival of deer, and thus a greater prey base for wolves, resulting from warmer winter temperatures during normal years), habitat losses could also result from wind, increased risk of fires, insect infestations, disease, and from changes to microclimate conditions for many plant and animal species, especially those species already found in unique habitat conditions.

[1] Maximum Forest Plan implementation is defined as the maximum harvest allowed by the Allowable Sale Quantity each decade. The estimate assumes all scheduled suitable POG is harvested [calculated by subtracting alternative-specific reduction factors for the Model Implementation Reduction Factor (MIRF) and scheduling from the mapped suitable acreage under each alternative (see the Timber section)].
[2] Based on an inventory of existing harvest on non-NFS lands and the estimation of future harvest by major landowner category.

The greatest concerns for plant and wildlife populations in relation to climate change, however, are the weather extremes that can be expected to occur periodically (CGC-ASR 1998). Periodic severe winter snowfalls are anticipated

(Juday et al. 1998). These events would be of greatest concern for populations that are limited in number or distribution. The predator-prey dynamic of wolves and deer provide an example of one system where these effects may be realized. Additional discussion on predator-prey dynamics can be found under the Wildlife section.

However, despite these uncertainties, the risks associated with implementation of the Forest Plan are very low. The life of this amendment is expected to be 10 to 15 years at most, by which time, much more research and monitoring information will be available and another comprehensive evaluation will be undertaken. The current levels of harvest activity are at a 5-decade low and even if timber sales are made available and the timber industry responds rapidly, there will be a period of preparation prior to the implementation of any sale. Therefore, it is estimated that a maximum of 30,000 to 150,000 acres of old-growth could be harvested over the life of this amended plan (e.g., the next 10 to 15 years). This harvest level would represent from less than 1 percent to 3 percent of the existing POG. Even when added to past harvest, cumulative harvest on NFS lands would be only 9 to 11 percent of the original POG.

Many of the gaps in information will be addressed through monitoring (See Chapter 6 in the Forest Plan). Additional studies stemming from adaptive management and known informational needs are discussed in Appendix B of the Forest Plan should assist land managers in the decision-making process to limit the degree of uncertainty and measure risk inherent in any decision into the future.

Cumulative Effects by Biogeographic Province

In the *Current Conditions by Biogeographic Province* subsection of *Affected Environment*, each biogeographic province is described with regard to past harvest and developments on both NFS and non-NFS lands of Southeast Alaska, and their effects on biodiversity. The following subsection builds on the previous subsection and discusses the cumulative effects associated with the past harvest and developments, when combined with the present and reasonably foreseeable harvest and developments on both NFS and non-NFS lands.

Yakutat Forelands

Past cumulative harvest in this biogeographic province removed 16 percent of the POG on all lands combined, resulting in 84 percent of the original POG remaining. Future harvest is expected to remove an additional 7 to 13 percent, resulting in approximately 71 to 77 percent of the original POG remaining after 100+ years (Table 3.9-20). High-volume POG is currently estimated to represent 81 percent of its original acreage. Future representation of high-volume POG is expected to be a minimum of 63 to 73 percent (Table 3.9-21). Similarly, large-tree POG is expected to decline from about 81 percent of original acreage at present, to a minimum of 63 to 78 percent after 100+ years (Table 3.9-22).

Currently, 83 percent of the large watersheds (representing 80 percent of the acreage) in the portion of the province within the Tongass Forest boundary are considered to be in an intact condition. After 100+ years, this percentage is expected to be reduced to a minimum of 58 to 67 percent (representing 71 to 73 percent of the acreage), depending on the alternative (Table 3.9-19). If the portion of the province that extends south into Glacier Bay National Park is included, the percentage of intact watersheds existing and remaining in the province after 100+ years would be substantially greater.

Cumulative effects on biodiversity associated with Alternatives 1 and 2 are expected to be slightly higher than existing conditions and concentrated in the area around Yakutat. Under these alternatives, future harvest would be mostly associated with non-NFS lands (there would be no NFS harvest under Alternative 1). Harvest on non-NFS lands would also be higher than harvest on NFS lands under all other alternatives. However, future NFS harvest associated with the other alternatives would approach the non-NFS harvest level. The extensive area of reserves in this province, under all alternatives, would limit effects on biodiversity. This is particularly true for Alternatives 1, 2, 3, 5, and 6, which include some acreage in the Old-Growth Habitat LUD designations, in addition to the large areas in Semi-Remote Recreation and LUD II and in Glacier Bay National Park that are associated with all the alternatives (65 percent of the province is in congressionally protected land designations). Further, Alternatives 1, 2, 3, and 6 would provide additional matrix retention as a result of the application of the legacy forest structure standard and guideline in two VCUs within the province.

Yakutat Uplands

The Yakutat Uplands province has experienced only limited past harvest equivalent to 6 percent of the original POG. Future cumulative harvest under all alternatives would also be limited to no more than several hundred additional acres. Therefore, approximately 93 to 94 percent of the original POG would be remaining after 100+ years (Table 3.9-20). In addition, future development would not change the percentage of large watersheds in an intact condition; they would remain at 96 percent of the watersheds or 99 percent of the acreage (Table 3.9-19). As a result of the limited extent of future development, cumulative effects on biodiversity are expected to be insignificant under any of the alternatives.

East Chichagof Island

Approximately 16 percent of the original POG in this province has been harvested, resulting in 84 percent of the original POG remaining. Following maximum future harvest after 100+ years, the percentage of original POG remaining would range from 64 percent (Alternative 7) to 78 percent (Alternative 1) (Table 3.9-20). High-volume POG is currently estimated to represent 76 percent of its original acreage. Future representation of high-volume POG is expected to be a minimum of 56 to 69 percent (Table 3.9-21). Similarly, large-tree POG is expected to decline from about 58 percent of original acreage at present, to a minimum of 46 to 54 percent after 100+ years (Table 3.9-22).

Currently, 53 percent of the large watersheds (representing 49 percent of the acreage) of the province are considered to be in an intact condition. After 100+ years, this percentage is expected to be reduced to a minimum of 31 to 52 percent (representing 26 to 47 percent of the acreage), depending on the alternative (Table 3.9-19). In addition to timber harvest, additional development associated with Hoonah and other communities in the province would contribute to cumulative effects.

Although specific watersheds would undergo a high cumulative percent harvest, Alternatives 1, 2, 3, 5, and 6 would result in the long-term retention of at least 71 percent of the original POG, 63 percent of the original high-volume POG, and 51 percent of the original large-tree POG. In addition, the conservation strategy in each of these alternatives would result in the spatial distribution of POG within reserves across the province. Further, Alternatives 1, 2, 3, and 6 would fully protect both pinch-points within the province by including them within reserves; Alternative 5 would fully protect one pinch-point and provide substantial protection to the second. Alternative 5 would not provide as much POG in reserves, but would provide more POG within the matrix because of the marten standards and guidelines. Alternatives 4 and 7, on the other hand, would not protect the pinch-point between northeast Chichagof and the main island. Further, because of a relatively low abundance and non-uniform distribution of reserves within the province, Alternative 7 and, to a lesser extent, Alternative 4, would likely result in gaps in the distribution of some organisms within the province and lower biodiversity.

West Chichagof Island

No past harvest has been mapped within the West Chichagof Island province and less than 200 acres (mostly on non-NFS lands) are projected to be harvested in the future. Therefore, the percentage of original POG remaining in the province after 100+ years would be almost 100 percent (Table 3.9-20). Future development is not expected to change the percentage of large watersheds in an intact condition either; currently this percentage is 100 percent. As a result, because of the very limited extent of future development, cumulative effects on biodiversity are expected to be virtually non-existent under any of the alternatives.

East Baranof Island

Past cumulative harvest in this biogeographic province has removed 13 percent of the POG on all lands combined, resulting in 87 percent of the original POG remaining. Future harvest is expected to remove an additional 1 to 17 percent, resulting in approximately 70 to 86 percent of the original POG remaining after 100+ years (Table 3.9-20). High-volume POG is currently estimated to represent 77 percent of its original acreage. Future representation of high-volume POG is expected to be a minimum of 60 to 76 percent (Table 3.9-21). Similarly, large-tree POG is expected to decline from about 33 percent of original acreage at present, to a minimum of 31 to 33 percent after 100+ years (Table 3.9-22). Therefore, although past large-tree POG harvest has been disproportionately high, the vast majority of remaining large-tree POG is in reserves and less than 10 percent of this remaining large-tree POG would be harvested under any of the alternatives.

Currently, 55 percent of the large watersheds (representing 60 percent of the acreage) are considered to be in an intact condition. After 100+ years, this percent age is expected to be reduced to a minimum of 45 percent (representing 49 percent of the acreage), depending on the alternative (Table 3.9-19).

Cumulative effects on biodiversity associated with Alternative 1 would be similar to those associated with existing conditions, because less than 1,000 additional acres of harvest would occur (on non-NFS lands). Alternatives 2, 3, 5, and 6 would result in a maximum of 6,000 to 11,000 additional acres of POG harvest. As is the case for East Chichagof Island province, specific watersheds would undergo high cumulative harvest under these alternatives; however, the conservation strategy would provide for extensive areas in reserves, distributed across the province, resulting in the retention of a minimum of 76 percent of original POG. Alternatives 4 and 7 would result in 15,000 to 17,000 additional acres of harvest and, although the southern half of the province would substantially be in reserves, the northern half would have large areas with no reserves, resulting in higher cumulative effects on biodiversity.

West Baranof Island

Approximately 8 percent of the original POG in this province has been harvested, resulting in 92 percent of the original POG remaining. Following maximum future harvest after 100+ years, the percentage of original POG remaining would range from 80 percent (Alternative 7) to 88 percent (Alternative 1) (Table 3.9-20). High-volume POG is currently estimated to represent 82 percent of its original acreage. Future representation of high-volume POG is expected to be a minimum of 68 to 77 percent (Table 3.9-21). Similarly, large-tree POG is expected to decline from about 44 percent of original acreage at present, to a minimum of 37 to 39 percent after

100+ years (Table 3.9-22). Therefore, as is the case for East Baranof Island province, although past large-tree POG harvest has been disproportionately high, the vast majority of remaining large-tree POG is in reserves and less than 10 percent of this remaining large-tree POG would be harvested under any of the alternatives.

Currently, 65 percent of the large watersheds (representing 69 percent of the acreage) of the province are considered to be in an intact condition. After 100+ years, this percentage is expected to be reduced to a minimum of 47 to 58 percent (representing 54 to 65 percent of the acreage), depending on the alternative (Table 3.9-19). In addition to timber harvest, additional development associated with Sitka and possible road and transmission line extensions within the province would contribute to cumulative effects.

Cumulative effects on biodiversity associated with Alternative 1 would only be associated with past harvest and non-NFS harvest because no NFS harvest would occur. Alternatives 2, 3, 5, and 6 would result in a maximum of 11,000 to 16,000 additional acres of POG harvest. As is the case for East Baranof Island province, specific watersheds would undergo high cumulative harvest under these alternatives; however, the conservation strategy would provide for extensive areas in reserves, distributed across the province, resulting in the retention of a minimum of 86 percent of original POG under these alternatives. In addition, Alternatives 1, 2, 3, and 6 would provide additional matrix retention as a result of the application of the legacy forest structure standard and guideline in four VCUs within the province. Under Alternatives 4 and 7, 28,000 to 31,000 additional acres of harvest (including non-NFS harvest) would occur and, although the southern half of the province would substantially be in reserves, the northern half would have large areas with no reserves, resulting in higher cumulative effects on biodiversity.

Admiralty Island

The Admiralty Island province has experienced 29,000 acres of past harvest; this represents only 5 percent of the original POG because of the size of the province and its extensive amount of POG. No NFS harvest would occur in the future and, although several thousand additional acres of harvest on non-NFS lands is expected to occur, the remaining POG would still be close to 95 percent of the original POG after 100+ years (Table 3.9-20). Similarly, high-volume POG is expected to change from about 94 to 93 percent and large-tree POG is expected to decrease from about 91 to 90 percent, purely as a result of non-NFS harvest.

Currently, 88 percent of the large watersheds (representing 85 percent of the acreage) of the portion of the province within the Tongass Forest boundary are considered to be in an intact condition. After 100+ years, this percentage is expected to be reduced to a minimum of 82 percent (representing 80 percent of the acreage) (Table 3.9-19). In addition to timber harvest, a proposed hydroelectric project and transmission line north of Angoon and continued operation and potential expansion of mining activity at Greens Creek would contribute to cumulative effects.

Although past and future harvest and development are concentrated in a few watersheds, which would experience relatively high effects on biodiversity, the cumulative effect on the overall biodiversity of the province is not expected to be high because of the expansive size and dominantly undeveloped nature of the province. Further, none of the future effects would be associated with NFS harvest. The vast majority of Admiralty Island would continue to remain intact under all alternatives and, as a result of the abundance of POG in this province, including high-volume and large-tree POG, it would continue to represent a massive reserve and reservoir for biological diversity in Southeast Alaska.

Lynn Canal

Past cumulative harvest in this biogeographic province has removed only 3 percent of the POG on all lands combined, resulting in 97 percent of the original POG remaining. Future harvest is expected to remove an additional 5 to 18 percent, resulting in approximately 79 to 92 percent of the original POG remaining after 100+ years (Table 3.9-20). High-volume POG is currently estimated to represent 95 percent of its original acreage. Future representation of high-volume POG is expected to be a minimum of 71 to 87 percent (Table 3.9-21). Similarly, large-tree POG is expected to decline from about 88 percent of original acreage at present, to a minimum of 64 to 78 percent after 100+ years (Table 3.9-22).

Currently, 76 percent of the large watersheds (representing 80 percent of the acreage) are considered to be in an intact condition. After 100+ years, this percent age is expected to be reduced to a minimum of 32 to 56 percent (representing 45 to 64 percent of the acreage), depending on the alternative (Table 3.9-19). In addition to timber harvest, continued development of areas around Juneau, Skagway, and Haines, the potential development of the Kensington Mine near Berners Bay, and the proposed development of the Juneau Access Road, would contribute to cumulative effects in this province.

Alternatives 1, 2, and 3 would result in a maximum of 5,000 to 12,000 acres of additional harvest resulting in the retention of at least 88 percent of original POG. Alternatives 5 and 6 would result in a maximum of 20,000 to 23,000 additional acres of POG harvest, resulting in the retention of a minimum of 84 percent of original POG. In addition, these five alternatives would incorporate a conservation strategy that would result in the spatial distribution of reserves, which would limit effects on biodiversity. Alternatives 4 and 7 would result in a maximum of 29,000 to 31,000 additional cumulative acres of harvest, which would produce a retention of at least 79 percent of the original POG. Even though there would be large areas with no reserves, the province would have extensive reserves even under Alternatives 4 and 7, which would limit effects on biodiversity.

Northern Coast Range

Approximately 6 percent of the original POG in this province has been harvested, resulting in 94 percent of the original POG remaining. Following maximum future harvest after 100+ years, the percentage of original POG remaining would range from 76 percent (Alternative 7) to 89 percent (Alternative 1) (Table 3.9-20). High-volume POG is currently estimated to represent 92 percent of its original acreage. Future representation of high-volume POG is expected to be a minimum of 70 to 83 percent (Table 3.9-21). Similarly, large-tree POG is expected to decline from about 77 percent of original acreage at present, to a minimum of 52 to 66 percent after 100+ years (Table 3.9-22).

Currently, 90 percent of the large watersheds (representing 94 percent of the acreage) of the province are considered to be in an intact condition. After 100+ years, this percentage is expected to be reduced to a minimum of 31 to 67 percent (representing 54 to 80 percent of the acreage), depending on the alternative (Table 3.9-19).

Harvest on NFS lands would not contribute to cumulative effects under Alternatives 1 and 2, and would contribute only in a minor way under Alternative 3. Almost all future harvest would be on non-NFS lands under these alternatives; long-term retention of POG would be about 88 to 89 percent. Under Alternatives 5 and 6, cumulative harvest would be a maximum of 48,000 to 52,000 acres; however, the conservation strategy under these two alternatives would provide for extensive areas in reserves, distributed across the province, resulting in the retention of a minimum of 81 percent of original POG. Under Alternatives 4 and 7, 65,000 to

68,000 additional acres of harvest (including non-NFS harvest) would occur and there would be large areas with no reserves, resulting in higher cumulative effects on biodiversity.

Kupreanof/Mitkof Islands

The Kupreanof/Mitkof Islands province has experienced 71,000 acres of past harvest, which represents 17 percent of the original POG; as a result, 83 percent of the original POG remains today. Following maximum future harvest after 100+ years, the percentage of original POG remaining would range from 53 percent (Alternative 7) to 74 percent (Alternative 1) (Table 3.9-20). High-volume POG is currently estimated to represent 71 percent of its original acreage. Future representation of high-volume POG is expected to be a minimum of 41 to 61 percent (Table 3.9-21). Similarly, large-tree POG is expected to decline from about 47 percent of original acreage at present, to a minimum of 29 to 42 percent after 100+ years (Table 3.9-22).

Currently, 37 percent of the large watersheds (representing 39 percent of the acreage) of the portion of the province within the Tongass Forest boundary are considered to be in an intact condition. After 100+ years, this percentage is expected to be reduced to a minimum of 8 to 31 percent (representing 9 to 30 percent of the acreage) (Table 3.9-19). In addition to timber harvest, additional development in the Petersburg and Kake areas and proposed additional road and transmission line development (especially between Petersburg and Kake) would contribute to cumulative effects.

Projected future cumulative harvest could be as high as 35,000 (Alternative 1) to 87,000 acres (Alternative 5) under Alternatives 1, 2, 3, 5, or 6. These harvest levels would result in the retention of 61 to 74 percent of the original POG, 49 to 61 percent of the original high-volume POG, and 34 to 42 percent of the original large-tree POG. These cumulative harvest levels would result in a reduction in habitat for species that prefer older forest stages (particularly larger tree types) and increases in habitat for species that prefer younger forest stages. However, the conservation strategy employed in each of these alternatives would result in POG being distributed in reserves and within the matrix across the province so that, although local reductions in biodiversity would be expected, habitat representation across the province would be maintained. Alternative 5 would not provide as much POG in reserves as Alternatives 1, 2, 3, and 6; however, it would provide more POG within the matrix because of the marten standards and guidelines. Under Alternatives 4 and 7, harvest could be as high as 104,000 to 119,000 additional acres, resulting in the retention of 53 to 57 percent of original POG, 41 to 44 percent of original high-volume POG, and 29 to 32 percent of large-tree POG. These cumulative harvest levels would result in greater reductions in habitat for species that prefer older forest stages, but more importantly, these alternatives would result in large expanses of habitat areas without POG in reserves, particularly under Alternative 7.

Kuiu Island

Past cumulative harvest in this biogeographic province has removed 9 percent of the POG on all lands combined, resulting in 91 percent of the original POG remaining. Future cumulative harvest is expected to remove from less than 1 percent (Alternative 1) to 22 percent of additional POG acreage, resulting in approximately 69 to 91 percent of the original POG remaining after 100+ years (Table 3.9-20). High-volume POG is currently estimated to represent 90 percent of its original acreage. Future representation of high-volume POG is expected to be a minimum of 66 to 89 percent (Table 3.9-21). Similarly, large-tree POG is expected to decline from about 82 percent of original acreage at present, to a maximum of 52 to 81 percent after 100+ years (Table 3.9-22).

Currently, 73 percent of the large watersheds (representing 60 percent of the acreage) are considered to be in an intact condition. After 100+ years, this percentage is expected to be reduced to a minimum of 47 to 73 percent (representing 34 to 60 percent of the acreage), depending on the alternative (Table 3.9-19).

Cumulative effects on biodiversity associated with Alternative 1 would only be associated with past harvest and non-NFS harvest because no NFS harvest would occur. Alternatives 2, 3, 5, and 6 would result in a cumulative maximum of 20,000 to 41,000 acres of additional harvest, resulting in the long-term retention of at least 79 to 85 percent of original POG, 75 to 82 percent of original high-volume POG, and 61 to 67 percent of original large-tree POG. In addition, these four alternatives would incorporate a conservation strategy that would result in the spatial distribution of reserves, which would limit effects on biodiversity. Alternatives 4 and 7 would result in a maximum of 62,000 to 72,000 additional cumulative acres of harvest, which would result in the retention of at least 69 to 72 percent of the original POG, 66 to 69 percent of high-volume POG, and 52 to 56 percent of large-tree POG. These two alternatives would result in large expanses of habitat areas without POG in reserves, which would increase their effects on biodiversity.

Central Coast Range

Approximately 3 percent of the original POG in this province has been harvested, resulting in 97 percent of the original POG remaining. Following maximum future harvest after 100+ years, the percentage of original POG remaining would range from 80 percent (Alternative 7) to 96 percent (Alternative 1) (Table 3.9-20). High-volume POG is currently estimated to represent 95 percent of its original acreage. Future representation of high-volume POG is expected to be a minimum of 79 to 94 percent (Table 3.9-21). Similarly, large-tree POG is expected to decline from about 89 percent of original acreage at present, to a minimum of 72 to 89 percent after 100+ years (Table 3.9-22).

Currently, 79 percent of the large watersheds (representing 85 percent of the acreage) of the province are considered to be in an intact condition. After 100+ years, this percentage is expected to be reduced to a minimum of 38 to 72 percent (representing 51 to 77 percent of the acreage), depending on the alternative (Table 3.9-19).

Additional harvest on NFS lands would not contribute to cumulative effects under Alternative 1 and only in a limited way under Alternative 2. Under Alternatives 3, 5, and 6, additional cumulative harvest would range from 20,000 acres to 31,000 acres, resulting in long-term POG retention of 85 to 89 percent, long-term high-volume POG retention of 84 to 87 percent, and long-term large-tree POG retention of 78 to 82 percent. The conservation strategy under these alternatives would provide for extensive areas in reserves, distributed across the province. Under Alternatives 4 and 7, 39,000 to 43,000 additional acres of harvest (including non-NFS harvest) would occur, resulting in long-term POG retention of 80 to 82 percent, long-term high-volume POG retention of 79 to 80 percent, and long-term large-tree POG retention of 72 to 73 percent. There would be some large areas with no reserves, under these two alternatives, resulting in higher cumulative effects on biodiversity.

Etolin Island and Vicinity

The Etolin Island and Vicinity province has experienced 41,000 cumulative acres of past harvest representing 15 percent of the original POG; as a result, 85 percent of the original POG remains today. Following maximum future harvest after 100+ years, the percentage of original POG remaining would range from 55 percent (Alternative 7) to 78 percent (Alternative 1) (Table 3.9-20). High-volume POG is currently estimated to represent 76 percent of its original acreage. Future representation of high-volume POG is expected to be a minimum of 45 to 67 percent (Table 3.9-21). Similarly, large-tree POG is expected to decline from about 51 percent of original acreage at present, to a minimum of 30 to 46 percent after 100+ years (Table 3.9-22).

Currently, 33 percent of the large watersheds (representing 30 percent of the acreage) of the portion of the province within the Tongass Forest boundary are considered to be in an intact condition. After 100+ years, this percentage is expected to be reduced to a minimum of 11 to 26 percent (representing 12 to 23 percent of the acreage) (Table 3.9-19). In addition to timber harvest, additional development in the Wrangell area would contribute to cumulative effects.

Projected future cumulative maximum harvest would be 19,000 acres under Alternative 1, resulting in 78 percent long-term POG retention. Under Alternatives 2, 3, 5, and 6 the cumulative maximum harvest would be 38,000 (Alternative 2) to 50,000 acres (Alternative 5). These harvest levels would result in the retention of 67 to 71 percent of the original POG, 57 to 61 percent of the original high-volume POG, and 39 to 42 percent of the original large-tree POG. These cumulative harvest levels would result in a reduction in habitat for species that prefer older forest stages (particularly larger tree types) and increases in habitat for species that prefer younger forest stages. However, the conservation strategy employed in each of these alternatives would result in POG being distributed in reserves and within the matrix across the province so that, although local reductions in biodiversity would be expected, habitat representation across the province would be maintained. The legacy forest structure standard and guideline would provide for additional POG in the matrix under Alternatives 1, 2, 3, and 6, and the marten standard and guideline would provide this for Alternative 5. Under Alternatives 4 and 7, harvest could be as high as 72,000 to 83,000 additional acres, resulting in the retention of 55 to 59 percent of original POG, 45 to 50 percent of original high-volume POG, and 30 to 33 percent of large-tree POG. These cumulative harvest levels would result in greater reductions in habitat for species that prefer older forest stages, but more importantly, these two alternatives would result in large expanses of habitat areas without POG in reserves. In addition, POG in the matrix would not be supplemented by either the legacy or the marten standard and guideline. As a result, these two alternatives would have a relatively high effect on province biodiversity.

North Central Prince of Wales Island

Approximately 35 percent of the original POG in this province has been harvested, resulting in 65 percent of the original POG remaining. Following maximum future harvest after 100+ years, the percentage of original POG remaining would range from 44 percent (Alternative 7) to 59 percent (Alternative 1) (Table 3.9-20). High-volume POG is currently estimated to represent 56 percent of its original acreage. Future representation of high-volume POG is expected to be a minimum of 33 to 45 percent (Table 3.9-21). Similarly, large-tree POG is expected to decline from about 55 percent of original acreage at present, to a minimum of 35 to 47 percent after 100+ years (Table 3.9-22).

Currently, 24 percent of the large watersheds (representing 17 percent of the acreage) of the province are considered to be in an intact condition. After 100+

years, this percentage is expected to be reduced to a minimum of 10 to 20 percent (representing 6 to 13 percent of the acreage), depending on the alternative (Table 3.9-19). In addition to timber harvest, additional development associated with Klawock, Craig, Thorne Bay, and the many other small communities in the province would contribute to cumulative effects.

Under Alternatives 1 and 2, additional cumulative harvest would range from 89,000 acres to 104,000 acres, resulting in long-term POG retention of 54 to 55 percent, long-term high-volume POG retention of 44 to 45 percent, and long-term large-tree POG retention of 45 to 47 percent. Projected future cumulative maximum harvest would be 118,000 to 131,000 acres under Alternatives 3, 5, and 6, resulting in 51 to 52 percent long-term POG retention, 41 to 42 percent long-term high-volume POG retention, and 43 to 44 percent long-term large-tree POG retention. The conservation strategy under Alternatives 1, 2, 3, 5, and 6 would provide for extensive areas in reserves, distributed across the province. In addition, the legacy forest structure standard and guideline would provide for additional POG in the matrix under Alternatives 1, 2, 3, and 6, and the goshawk and marten standards and guidelines would provide this for Alternative 5. Alternatives 1, 2, 3, and 6 would provide reserves to maintain connectivity for the Neck Lake pinch-point, while Alternative 5 would provide for some connectivity. These alternatives also would provide a number of reserves in the Sulzer Portage pinch-point area to enhance connectivity. Under Alternatives 4 and 7, 150,000 to 198,000 additional acres of harvest (including non-NFS harvest) would occur, resulting in long-term POG retention of 44 to 49 percent, long-term high-volume POG retention of 33 to 39 percent, and long-term large-tree POG retention of 35 to 40 percent. Alternative 4 would supplement the pool of non-development LUDs in this province with an array of Old-Growth Habitat LUD areas, although the extent of reserves would be less than under Alternatives 1, 2, 3, 5, or 6. Alternative 7, on the other hand, would not include Old-Growth Habitat LUDs and would have large areas with no reserves. In addition, POG in the matrix would not be supplemented by either the legacy or the marten standard and guideline. Alternative 4 would provide for some connectivity at the Neck Lake pinch-point, but would not provide much in the way of reserves near the Sulzer Portage pinch-point. Alternative 7 would provide not provide very few acres of reserves in the vicinity of either pinch-point. As a result, Alternative 4 would have a relatively high effect on province biodiversity and Alternative 7 would have a very high effect. Alternative 7 and, to a lesser extent, Alternative 4, would likely result in gaps in the distribution of some organisms within the province and lower biodiversity.

Revilla Island/Cleveland Peninsula

The Revilla Island/Cleveland Peninsula province has had 71,000 cumulative acres of past harvest representing 11 percent of the original POG; as a result, 89 percent of the original POG remains today. Following maximum future harvest after 100+ years, the percentage of original POG remaining would range from 66 percent (Alternative 7) to 81 percent (Alternative 1) (Table 3.9-20). High-volume POG is currently estimated to represent 84 percent of its original acreage. Future representation of high-volume POG is expected to be a minimum of 58 to 74 percent (Table 3.9-21). Similarly, large-tree POG is expected to decline from about 59 percent of original acreage at present, to 44 to 55 percent after 100+ years (Table 3.9-22).

Currently, 68 percent of the large watersheds (representing 71 percent of the acreage) of the portion of the province within the Tongass Forest boundary are considered to be in an intact condition. After 100+ years, this percentage is expected to be reduced to a minimum of 33 to 55 percent (representing 43 to 60 percent of the acreage) (Table 3.9-19). In addition to timber harvest, additional development in the Ketchikan, Saxman, and Metlakatla areas, including the Swan-Tyee transmission line (under construction), would contribute to cumulative effects.

Projected future cumulative maximum harvest would be 49,000 acres to 77,000 acres under Alternatives 1, 2, and 3, resulting in 77 to 81 percent long-term POG retention, 70 to 74 percent of the original high-volume POG retention, and 52 to 55 percent of the original large-tree POG retention. Under Alternatives 5 and 6 the cumulative maximum harvest would be 94,000 acres. These harvest levels for Alternatives 5 and 6 would result in the retention of 74 percent of the original POG, 68 percent of the original high-volume POG, and 50 percent of the original large-tree POG. These cumulative harvest levels would result in a reduction in habitat for species that prefer older forest stages (particularly larger tree types) and increases in habitat for species that prefer younger forest stages. However, the conservation strategy employed in each of these alternatives would result in POG being distributed in reserves and within the matrix across the province so that, although local reductions in biodiversity would be expected, habitat representation across the province would be maintained. The legacy forest structure standard and guideline would provide for additional POG in the matrix under Alternatives 1, 2, 3, and 6, and the marten standard and guideline would provide this for Alternative 5. Under Alternatives 4 and 7, harvest could be as high as 128,000 to 151,000 additional acres, resulting in the retention of 66 to 69 percent of original POG, 58 to 62 percent of original high-volume POG, and 44 to 46 percent of large-tree POG. These cumulative harvest levels would result in greater reductions in habitat for species that prefer older forest stages, but more importantly, these two alternatives (especially Alternative 7) would result in large expanses of habitat areas without POG in reserves. In addition, POG in the matrix would not be supplemented by either the legacy or the marten standard and guideline. As a result, these two alternatives would have a relatively high effect on province biodiversity.

Southern Outer Islands

Approximately 15 percent of the original POG in this province has been harvested, resulting in 85 percent of the original POG remaining. Following maximum future harvest after 100+ years, the percentage of original POG remaining would range from 72 percent (Alternative 7) to 80 percent (Alternative 1) (Table 3.9-20). High-volume POG is currently estimated to represent 77 percent of its original acreage. Future representation of high-volume POG is expected to be a minimum of 61 to 70 percent (Table 3.9-21). Similarly, large-tree POG is expected to decline from about 67 percent of original acreage at present, to a minimum of 49 to 60 percent after 100+ years (Table 3.9-22).

Currently, 50 percent of the large watersheds (representing 64 percent of the acreage) of the province are considered to be in an intact condition. After 100+ years, this percentage is expected to be reduced to a minimum of 45 to 50 percent (representing 59 to 64 percent of the acreage), depending on the alternative (Table 3.9-19).

Most of the islands that make up this province are entirely in reserves under all alternatives. Harvest would be limited to Heceta and Suemez in all alternatives, as well as San Juan Bautista Islands in Alternatives 3, 5, and 6. Alternatives 1, 2, 3, 5, and 6 would result in the maximum future cumulative harvest of 7,000 to 12,000 acres, producing a long-term retention of 76 to 80 percent of the original POG, 66 to 70 percent of the original high-volume POG, and 56 to 60 percent of the original large-tree POG. The conservation strategy in each of these alternatives would result in the spatial distribution of POG within reserves across the province. Under Alternatives 4 and 7, harvest could be as high as 14,000 to 19,000 additional acres, resulting in the retention of 72 to 75 percent of original POG, 61 to 64 percent of original high-volume POG, and 49 to 53 percent of large-tree POG. These latter two alternatives would result larger habitat areas without POG in reserves.

Dall Island and Vicinity

Past cumulative harvest in this biogeographic province has removed 25 percent of the POG on all lands combined, resulting in 75 percent of the original POG remaining. Future cumulative harvest is expected to remove from less than 17 percent (Alternative 1) to 22 percent of additional POG acreage, resulting in approximately 53 to 58 percent of the original POG remaining after 100+ years (Table 3.9-20). The vast majority of this future harvest is on non-NFS lands under all alternatives. High-volume POG is currently estimated to represent 77 percent of its original acreage. Future representation of high-volume POG is expected to be a minimum of 61 to 70 percent (Table 3.9-21). Similarly, large-tree POG is expected to decline from about 42 percent of original acreage at present, to a minimum of 36 to 37 percent after 100+ years (Table 3.9-22). The great majority of this retention would be in reserves.

Currently, 71 percent of the large watersheds (representing 53 percent of the acreage) are considered to be in an intact condition. After 100+ years, this percentage is expected to be reduced to a minimum of 29 to 34 percent (representing 15 to 19 percent of the acreage), depending on the alternative (Table 3.9-19).

The maximum cumulative future harvest would be 23,000 to 29,000 acres under all of the alternatives, with 23,000 acres of harvest on non-NFS lands and from 0 to 6,000 acres on NFS lands. At least 80 percent of the original POG on NFS lands would be in reserves under all alternatives. The only area on NFS harvest would be at the extreme northwestern corner of Dall Island with no harvest planned on Long Island. The reserves on Dall Island stretch the entire length of the island on the west side. Therefore, although a substantial portion of the non-NFS POG is expected to be harvested, the contribution by NFS harvest would be relatively small.

South Prince of Wales

The South Prince of Wales Island province has had 18,000 cumulative acres of past harvest representing 9 percent of the original POG; as a result, 91 percent of the original POG remains today. Following maximum future harvest after 100+ years, the percentage of original POG remaining would range from 68 percent (Alternative 7) to 87 percent (Alternative 1) (Table 3.9-20). High-volume POG is currently estimated to represent 88 percent of its original acreage. Future representation of high-volume POG is expected to be a minimum of 64 to 83 percent (Table 3.9-21). Similarly, large-tree POG is expected to decline from about 88 percent of original acreage at present, to a minimum of 65 to 85 percent after 100+ years (Table 3.9-22).

Currently, 78 percent of the large watersheds (representing 75 percent of the acreage) of the portion of the province within the Tongass Forest boundary are considered to be in an intact condition. After 100+ years, this percentage is expected to be reduced to a minimum of 47 to 72 percent (representing 45 to 69 percent of the acreage) (Table 3.9-19).

Projected future cumulative maximum harvest would be 8,000 acres to 26,000 acres under Alternatives 1, 2, 3, 5, and 6, resulting in 77 to 87 percent long-term POG retention, 73 to 83 percent of the original high-volume POG retention, and 76 to 85 percent of the original large-tree POG retention. The conservation strategy employed in each of these alternatives would result in POG being distributed in reserves and within the matrix across the province so that, although local reductions in biodiversity would be expected, habitat representation across the province would be maintained. The goshawk and marten standards and guidelines would provide additional POG in the matrix in this province under Alternative 5. Under Alternatives 4 and 7, harvest could be as high as 37,000 to 43,000 additional acres, resulting in the retention of 68 to 71 percent of original POG, 64 to 67 percent of original high-volume POG, and 65 to 69 percent of large-tree POG. In all alternatives, large reserves exist in the southern and western portions of the province. However, Alternatives 4 and 7 do not include reserves over large areas in the north and east parts of the province, as well as portions of the west. As a result, these two alternatives would have a higher effect on province biodiversity.

North Misty Fiords

Only 2,000 acres of past harvest has occurred in the North Misty Fiords province, and up to 7,000 acres is projected for the future. As a result, a minimum of 95 percent of the POG originally found in the province is expected to be retained long term, relative to the 99 percent at present (Table 3.9-20). Similarly, neither high-volume nor large-tree POG are expected to drop below 90 percent of their original acreages. Also, future development is not expected to reduce the percentage of large watersheds in intact condition to less than 88 percent by number or 91 percent by acreage, under any of the alternatives (Table 3.9-19). Therefore, because of the very limited extent of future development, cumulative effects on biodiversity are expected to be very low under any of the alternatives.

South Misty Fiords

No past harvest has been mapped within the South Misty Fiords province and less than 200 acres (on non-NFS lands) are projected to be harvested in the future. Therefore, the percentage of original POG remaining in the province after 100+ years would be almost 100 percent (Table 3.9-20). Future development is not expected to change the percentage of large watersheds in an intact condition either; currently this percentage is 100 percent. As a result, because of the very limited extent of future development, cumulative effects on biodiversity are expected to be virtually non-existent under any of the alternatives.

Ice Fields

Approximately 3 percent of the original POG in this province has been harvested, resulting in 97 percent of the original POG remaining. Following maximum future harvest after 100+ years, the percentage of original POG remaining would range from 93 percent (Alternative 7) to 97 percent (Alternative 1) (Table 3.9-20). High-volume POG is currently estimated to represent 93 percent of its original acreage. Future representation of high-volume POG is expected to be a minimum of 90 to 93 percent (Table 3.9-21). Similarly, large-tree POG is expected to decline from about 83 percent of original acreage at present, to a minimum of 81 to 83 percent after 100+ years (Table 3.9-22).

Currently, 93 percent of the large watersheds (representing 94 percent of the acreage) of the province are considered to be in an intact condition. After 100+ years, this percentage is expected to be reduced to a minimum of 82 to 88 percent (representing 88 to 94 percent of the acreage), depending on the alternative (Table 3.9-19).

Cumulative effects on biodiversity associated with Alternative 1 would only be associated with past harvest because no NFS harvest and only a few acres of non-NFS harvest would occur. Alternatives 2, 3, 4, 5, 6 and 7 would result in a cumulative maximum of 1,000 to 4,000 acres of additional harvest, resulting in the long-term retention of at least 93 percent of original POG, 90 percent of high-volume

POG, and 81 percent of large-tree POG. The vast majority of this POG is in reserves (Table 3.9-14). Therefore, although local watershed effects are expected, cumulative effects on biodiversity at the province level are expected to be minor.

Chilkat River Complex

The Chilkat River Complex province has had about 21,000 acres of past harvest, representing 12 percent of the original POG; therefore, 88 percent of the original POG remains today. The province lies entirely outside the Forest boundary, so there would be no future harvest on NFS lands associated with any of the alternatives. Approximately 32 percent of the existing POG, 26 percent of existing high-volume POG, and 11 percent of existing large-tree POG stands are located in reserves.

Future cumulative harvest associated with state and private lands in the province, could result in up to 52,000 additional acres of POG harvest after 100+ years (Table 3.9-20). With this additional harvest, the POG retention would amount to a minimum of 56 percent, with a minimum of 60 percent retention for high-volume POG and 32 percent retention for large-tree POG. In addition, future development associated with Haines and Skagway could contribute to cumulative effects within the province.

Tongass management would not contribute to cumulative effects within the province and would only contribute to a regional effect, relative to multiple adjacent provinces. The three provinces that are adjacent to the Chilkat River Complex are the Glacier Bay/Fairweather Range, the Ice Fields, and the Lynn Canal provinces. Among these three, the Lynn Canal province would be managed with the highest intensity. However, even in the Lynn Canal province, the long-term retention of POG would be 79 to 92 percent, depending on the alternative. The Ice Fields and Glacier Bay/Fairweather Range provinces would retain 93 to 100 percent of their POG under any alternative (Table 3.9-20).

Glacier Bay/Fairweather Range

Past harvest within the Glacier Bay/Fairweather Range province has been limited to a few hundred acres. Similarly, negligible future cumulative harvest is projected under all alternatives. As a result, the percentage of original POG remaining in the province after 100+ years would be almost 100 percent (Table 3.9-20). Future development is not expected to change the percentage of large watersheds in an intact condition either; currently this percentage is also close to 100 percent because of Glacier National Park. Therefore, because of the very limited extent of future development, cumulative effects on biodiversity are expected to be negligible under any of the alternatives.

Wildlife

Affected Environment

The Tongass National Forest supports a rich array of wildlife species, providing habitat for approximately 54 species of mammals, 231 species of birds, and 5 species of amphibians and reptiles. There are an additional 18 species of marine mammals found in Southeast Alaska that depend entirely on the ocean environment, as well as 45 bird and 3 amphibian or reptile species considered casual or accidental visitors to Southeast Alaska. Some species that are relatively abundant on the Forest (e.g., bald eagles and brown bears) are listed as threatened or endangered in other parts of their range, and others are endemic to the Tongass (essentially found nowhere else in the world) and may occupy ranges limited to single islands. Other species have wide geographic ranges and are found elsewhere in Alaska, Canada, and the lower 48 states. The diversity of wildlife on the Forest provides many opportunities for consumptive and non-consumptive uses including commercial, general, and subsistence hunting; and photographic and viewing activities.

This section provides an overview of wildlife habitats on the Tongass, describes current management regimes related to wildlife habitat and relevant policies, and provides information on key species and their habitats. The consumptive uses of wildlife are also briefly discussed. This section also addresses issues related to invasive species and endemism. Updated information presented at an interagency review of the Forest Plan Conservation Strategy, held in Ketchikan, Alaska, in April 2006, is incorporated and referenced where appropriate. This workshop took into account new literature published since 1997 as well as ongoing research and included the presentation of preliminary results.

Approximately 55 percent of the 16.8 million acres of the Tongass National Forest consists of temperate rainforest (see Figure 3.9-3 of the *Biodiversity* section). This includes both productive and non-productive old growth (POG), a classification that relates to the ability of a stand to grow trees of a certain size or volume per acre. Ninety-eight percent of the POG on the Tongass is dominated by Sitka spruce and western hemlock, both of which occur throughout Southeast Alaska. Approximately

4 percent of the Tongass is young-growth forest (both natural and harvested), primarily distributed among four biogeographic provinces (North Central Prince of Wales, Etolin Island, Kupreanof/Mitkof, andRevillagigedo Island/Cleveland Peninsula). The remaining 41 percent of the Tongass consists non-forested habitat that includes sparsely vegetated areas of shrub and herbaceous (e.g., muskegs, alpine, estuaries), non-vegetated areas (e.g., snow, rock, ice), and aquatic sites (e.g., streams, ponds, and lakes). Tables 3.9-2 and 3.9-3 in the *Biodiversity* section show the distribution of forested and non-forested cover types on the Tongass.

Old-Growth Habitat and the Conservation Strategy

Although many wildlife species on the Tongass are associated with more than one habitat type, most inhabit old-growth forests or prey on species that inhabit old-growth forests. Old growth is characterized by a patchy, multi-layered canopy; trees that represent many age classes; large trees that dominate the overstory, standing dead (snags) or decadent trees; and higher accumulations of down woody material. The structure and function of an old-growth ecosystem will be influenced by stand size, landscape position, and juxtaposition with other elements of the landscape. POG can be broken down further in terms of seven categories based on tree size and density. See the Old-Growth Forest subsection in the Affected Environment portion of the *Biodiversity* section of this document, including Figures 3.9-4 and 3.9-5, for a detailed discussion of old growth on the Tongass and the size-density model (SDM).

The 1997 Forest Plan established a comprehensive, science-based old-growth conservation strategy to address wildlife sustainability and viability. This strategy was based on careful analysis and integration of the best scientific information available at that time and is comprised of two key components.

The first is a Forest-wide reserve network that is designed to protect the integrity of the existing old-growth ecosystem. It incorporates a network of small, medium, and large old-growth reserves (OGRs) and other non-development Land Use Designations (LUDs), which protect 71 percent of the existing POG on the Tongass National Forest (Appendix D).

The second component of the conservation strategy is a set of standards and guidelines that apply in the development LUDs where commercial timber harvesting is permitted (referred to as the matrix). In these areas, the standards and guidelines sustain key components of the landscape that the available scientific information indicates is important for wildlife. These include a 1,000-foot buffer along the entire marine shoreline and riparian buffer corridors. Standards and guidelines established for other reasons, also contribute protected old growth. Finally, assuming the maximum level of timber harvest permitted by the Forest Plan, there are additional areas that are not scheduled for harvest due to economic considerations. Collectively, these standards and guidelines and unscheduled areas would maintain at least 66 percent of the POG within the matrix or over 19 percent of all POG on the Tongass (Appendix D).

Overall, the conservation strategy in the 1997 Forest Plan protects slightly more than 90 percent of all existing POG forests on the Tongass. It is important to note that this percentage assumes that old-growth forest is harvested at the maximum allowable rate in each future decade before sufficient second-growth forest has reached harvestable size and can replace old growth in the harvest. If this maximum rate does not occur, then the percentage of POG retained will be higher. A more detailed description of the Tongass conservation strategy, and the basis for its development, is provided below under effects, in the *Biodiversity* section, and in Appendix D.

Landscape Connectivity and Fragmentation

Landscape connectivity is defined as the degree to which the structure of a landscape helps or hinders the movement of wildlife species (Taylor et al. 1993). A "well-connected" landscape enables organisms to readily move among habitat patches over the long term. Fragmentation is the loss of connectivity across the landscape and is a substantial threat to many species, especially those that are smaller or less mobile. Fragmentation occurs when large blocks of habitat are broken into smaller parcels by natural (e.g., wind throw) or human induced (e.g., roads or timber operations) forces. As habitat is lost or fragmented, residual habitat patches become smaller and more isolated from each other. This limits the movement of species and, through their increased isolation, puts them at greater risk of extirpation. Open spaces left by fragmentation can act as travel barriers for some species, or increase the risk of predation for other species that venture across them (see the *Biodiversity* section for additional discussion on fragmentation).

There are two types of landscape connectivity that can be considered: structural and functional connectivity (Brooks et al. 2003). Structural connectivity describes the physical relationships among habitat patches, generally ignoring the behavioral response of organisms to landscape structure. Landscape corridors, or areas of continuous habitat that link similar habitat patches in a landscape and thus facilitate the movement of species among isolated habitat patches, are representative of structural connectivity. On the Tongass, intact riparian buffers and the beach fringe function as corridors that facilitate dispersal and allow movement between small, isolated subpopulations of species. Advances in the fields of landscape ecology, habitat fragmentation, and population genetics have led to a broader view of connectivity, with less of a structured focus on corridors, and more of a perspective on the functional connectivity provided by landscape linkages or "linkage zones" (Bennett 1999 as cited in Haufler 2007). Functional connectivity relates to the degree of movement or flow of organisms through the landscape. Linkage zones are not necessarily discrete features of the landscape, but may occur where the juxtaposition of particular habitats or land uses act to funnel dispersers between habitat patches. The concept of functional connectivity addresses movement capabilities of individual species, habitat patches, landscape configurations, matrix conditions, barriers, and their relationships in maintaining continuous populations (Haufler 2007). On the Tongass, matrix lands play a vital role as landscape linkages because they provide functional connectivity between OGRs and other non-development land use areas.

The National Forest Management Act (NFMA) regulations provide that habitat must be "well distributed" so that "individuals can interact with others in the planning area." The continued existence of a population within which interaction between individuals becomes difficult (significantly less frequent) or impossible may no longer be well distributed, as segments of the population become isolated. The fragmentation of habitats, which isolates and creates small insular populations, contributes to decreased population distribution and increased likelihood of local extirpation (Wilcove et al. 1986). Because the Tongass is an island archipelago, relatively isolated populations may already exist with naturally higher risks to local extirpation (see discussion of endemism below).

The idea of maintaining well-distributed habitats brings up the issue of scale, which is a fundamental difficulty underlying the assessment of functional landscape connectivity. For example, because species differ in their dispersal abilities and, therefore, the way they perceive patches as functionally connected, the scale of the interaction between the species and the landscape should be taken into account when assessing the connectedness of the landscape. That is, there are likely features within the matrix that are not conducive to crossing by some species that are most appropriately identified at the project level, rather than on a Forest-wide basis. As such, the following discussion takes a broader view of connectivity by focusing on areas where natural or human-caused features (e.g., roads and clearcuts) constrain potential movement by wildlife to narrow bands of habitat, often referred to as “pinch-points” or “bottlenecks.”

These points often function as movement corridors and need special planning and design to ensure that wildlife migration patterns and habitat diversity are protected over the long term and are thus an important aspect in considering functional landscape connectivity. Additionally, determining if management activities are likely to create barriers that could affect species distribution on a landscape scale (e.g., within biogeographic provinces) is a useful means of identifying potential adverse short-term effects on maintaining well distributed, viable populations.

“Pinch-points” can be geographic or ecologically based. For example, areas have been identified on the Tongass where geographic “pinch-points” connect major landscapes within islands. These are all relatively narrow areas between larger land units where future alterations in habitat could significantly reduce natural connectivity and limit the ability of land-based species to disperse or migrate. The following is a description of six key areas, identified by the Interdisciplinary Team (IDT) during the development of the 1997 Forest Plan, where a high amount of development has occurred; there are a number of additional pinch-points (e.g., the Cleveland peninsula between Santa Ana and Yes Bay and between Neets and Shrimp Bay) where concentrated harvest is less likely to occur during the life of the Forest Plan, which should be analyzed at the project level:

1. The portage between Tenakee Inlet and West Port Frederick on Chichagof Island, a narrow neck of land connecting northeast Chichagof Island to the main body of the rest of the island. This is in the East Chichagof biogeographic province.
2. The area connecting Lisianski Inlet with the North Arm of Peril Strait is a narrow region that connects two major portions of Chichagof Island.
3. The area between Port Camden, Bay of Pillars, and 3-Mile Arm on Kuiu Island (Kuiu Island biogeographic province), a narrow neck of land connecting the northern and eastern part of the island to the rest of Kuiu Island.
4. The narrow area between Lindenburg Peninsula and the remainder of Kupreanof Island.
5. The Neck Lake area between Whale Passage and El Capitan Passage on Prince of Wales Island (North Central Prince of Wales biogeographic province) has experienced high levels of past and ongoing forest management activities. It also is a relatively narrow piece of land connecting the extreme northern end of Prince of Wales Island to the remainder of the island.
6. Sulzer Portage, between the West Arm Cholmondeley Sound and Portage Bay at the head of Hetta Inlet, on Prince of Wales Island. This area has had considerable timber harvesting on both National Forest and adjacent private lands, and due to a recent transfer of land ownership the pinch-point itself is now all private land. This relatively narrow neck of land joins the southeast part of Prince of Wales Island to the remainder of the island, connecting North Central and South Prince of Wales biogeographic provinces.

Ecological “pinch-points” are areas where habitat conditions within a landscape facilitate movement between habitat patches. These areas may be peninsulas of forested habitat surrounded by nonforested habitat that receive concentrated wildlife use and can best be identified by conducting a landscape connectivity analysis. Some species are very mobile through a variety of habitat conditions and some need relatively intact mature forest to successfully travel. Some conditions, such as large water crossings, present a barrier to movement to some species and not to others. For most species, however, connectivity is not an either/or function. Pyare and Smith (2005, 2006) conducted a preliminary evaluation of functional connectivity on the Tongass by experimentally evaluating the movement potential of flying squirrels through various landscape elements in an intensively managed area on Prince of Wales Island to derive a spatial model to evaluate movement potential at a larger scale. Experiments revealed that flying squirrels moved with the least resistence across large expanses of old-growth and old-growth fragments, followed by second-growth up to 100 meters wide, with the most resistence in regenerating clearcuts and young second growth greater than 100 meters wide. Noteably, while males appeared to have a high movement potential in fragmented landscapes, females and juveniles did not. This detailed level of pinch-point analysis is necessarily done at a finer scale during project planning or landscape analyses (Smith and Pyare 2005, 2006).

Species Accounts

The following species accounts are divided into five sections: Threatened and Endangered Species, Candidate Species, Forest Service Sensitive Species, Management Indicator Species, and Other Species of Concern. Species on "sensitive lists" compiled by other entities (e.g., Boreal Partners in Flight, Alaska Natural Heritage Program, and Alaska Department of Fish and Game (ADF&G) Nongame) are addressed through the Regional Forester's sensitive species list. This list is in the process of being updated. Table 3.10-1 lists all species considered for this section.

Threatened and Endangered Species

Federally listed threatened and endangered species are those plant and animal species formally listed by the U.S. Fish and Wildlife Service (USFWS) or National Marine Fisheries Service (NMFS) under authority of the Endangered Species Act (ESA) of 1973, as amended. An endangered species is defined as one that is in danger of extinction throughout all or a significant portion of its range. A threatened species is defined as one that is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range.

The federally listed wildlife species within the boundary of the Tongass National Forest include humpback whale (*Megaptera novaeangliae*) and Steller sea lion (*Eumetopias jubata*). Recovery plans have been prepared for the humpback whale and Steller sea lion. The ESA for the State of Alaska authorizes the Commissioner of the ADF&G to list Alaska endangered species. Species listed as endangered by the State of Alaska include the short-tailed albatross (*Diomedea albatrus*), humpback whale, right whale (*Eubalaena glacialis*), and blue whale (*Balaenoptera musculus*). With the exception of the humpback whale, none of these species occur in Southeast Alaska and therefore are not considered further here.

Pursuant to Section 7 of the ESA, a Biological Assessment was prepared to assess the effects of the 1997 Forest Plan revision on endangered or threatened species and ensure that proposed actions would not jeopardize the continue existence of listed species (specifically, humpback whale and the eastern population of the Steller sea lion) and was submitted to NMFS for review and concurrence. The Biological Assessments and agency concurrences for the Forest Plan revision can be found in Appendix J of the 1997 Forest Plan Revision Final EIS. Humpback whales and Steller sea lions will not be addressed further in this document, but are evaluated in an updated Biological Assessment prepared for the current Forest Plan amendment (Appendix F).

The Queen Charlotte goshawk and the Alexander Archipelago wolf were both the subject of listing petitions under the ESA in the 1990s; the petitions were reviewed and formally accepted by USFWS in 1994. USFWS concluded in 1995 that listing was not warranted for either subspecies, but concerns remained for their long-term viability. The goshawk finding was challenged in U.S. District Court, which remanded the finding to USFWS with instructions to base the finding on the existing management plan for the Tongass (the 1997 Forest Plan), rather than the one in

Table 3.10-1
Wildlife Species in Southeast Alaska that are Federally Listed Species or Candidate for Listing under the ESA (NMFS or USFWS), Management Indicator Species (USDA Forest Service), or Sensitive Listed Species (USDA Forest Service)

Species Common Name (*Scientific Names*)[2/]	Federal T&E Listed Species	Federal Candidate Species	Management Indicator Species[1]	Forest Service Sensitive Listed Species [2]	Other Species of Concern

[1] This document addresses all Management Indicator Species listed in the 1997 Forest Plan.
[2] Listed plant and fish species are addressed in their respective sections.

development at the time. USFWS released a new finding in August 1997, which also concluded that listing was not warranted. Several more legal challenges occurred in the intervening years and, most recently, the court instructed the USFWS to evaluate whether Vancouver Island is a "significant portion of the subspecies' range and, if so, to determine whether the bird should be listed. A new Finding, released in November 2007 concluded that that Vancouver Island is a significant portion of the Queen Charlotte goshawk's range and that listing the subspecies on Vancouver Island is warranted. The review also indicated that the subspecies' populations in British Columbia and Alaska are distinct population segments (DPS) and that the best available information on biological vulnerability and threats to the goshawk does not support listing the Alaska DPS as threatened or endangered at this time.

The Kittlitz's murrelet is a candidate species for listing. Species accounts for the Kittlitz's murrelet, Queen Charlotte goshawk, and Alexander Archipelago wolf are provided below under the Candidate Species subsection, Forest Service Sensitive Species subsection, and Management Indicator Species subsection, respectively.

Candidate Species

Kittlitz's Murrelet

On May 9, 2001, the Secretary of the Interior was petitioned to list the Kittlitz's murrelet (*Brachyramphus brevirostris*) as endangered with concurrent designation of critical habitat under the ESA. Petitioners cited dramatic reductions in population size over the past decade and declining habitat quality as reasons for the requested listing. The species was officially designated a candidate species (warranted, but precluded) on May 4, 2004.

The Kittlitz's murrelet is closely associated with glacial habitats along the Alaska mainland coast. Breeding sites are usually chosen in the vicinity of glaciers and cirques in high-elevation alpine areas with little or no vegetative cover (van Vliet 1993). When present, vegetation is primarily composed of lichens and mosses (Day et al. 1983). The species nests a short distance below the peak or ridge on coastal cliffs, barren ground, rock ledges, and talus above timberline in coastal mountains, generally near glaciers 0.2 to 47 miles inland (Day et al. 1983). The remote and solitary nesting habits lead to extreme difficulty in finding nests. Non-breeding or off-duty breeders spend the summer in inshore areas, especially along glaciated coasts.

The Kittlitz's murrelet is one of the rarest seabirds in North America. The only American population occurs in Alaskan waters from Point Lay south to northern Southeast Alaska (Endicott and Tracey Arm). The largest breeding populations are believed to be in Glacier Bay National Park and Preserve, Prince William Sound, Kenai Fjords, and Icy Bay (Kendall and Agler 1998 as cited in Day et al. 2000). According to the petition, the southern boundary of the breeding range is LeConte Bay on the Tongass National Forest. Latest worldwide population estimates range from 9,500 to 26,500 birds. The best information available from USFWS indicates that Prince William Sound populations have declined by 84 percent since 1984, Kenai Fjords area by 83 percent since 1976, Malaspina Forelands by 38 percent and perhaps as much as 75 percent between 1992 and 2002, and Glacier Bay by 60 percent between 1990 and 1999. Speculated causes for decline include oil pollution, glacial recession, gillnet mortality, and availability of preferred forage fish (Kuletz et al. 2003, Piatt and Anderson 1996, van Vliet and McAllister 1994). Effects of these factors include increased adult and juvenile mortality and low recruitment. Human-caused mortality includes gillnet fisheries and oil spills like that from the Exxon Valdez or smaller tourism and fishing boats. Increased disturbance from helicopter tours and cruise ships may also be a factor.

Forest Service Sensitive Listed Species

Sensitive species are those plant and animal species identified by the Regional Forester for which population viability is a concern on National Forest System (NFS) lands within the region. Either a significant current or predicted downward trend in population numbers or density, or a significant current or predicted downward trend in habitat capability that would reduce a species' existing distribution indicates a viability concern. The goal of the Forest Service Sensitive Species Program (Forest Service Manual 2670) is to ensure that species numbers and population distribution are adequate so that no federal listing will be required and no extirpation will occur on NFS land. The Alaska Region Sensitive Species List was last updated in June 2002 and an update is currently in progress.

Plants and fish species identified as Sensitive are discussed in their respective sections. The Queen Charlotte goshawk is described in greater detail because this species has additional management concerns. The Regional Sensitive Species List continues to be revised as new information dictates.

Queen Charlotte Goshawk

The northern goshawk inhabits forested lands throughout North America, favoring dense stands of conifer or deciduous mature and/or old growth for nesting habitat. The Queen Charlotte goshawk is recognized as a distinct subspecies, and is endemic to coastal rainforests from Vancouver Island to northern Southeast Alaska (Taverner 1940, Iverson et al. 1996, Squires and Reynolds 1997). Recent genetic analysis indicates that this population may be genetically distinct from goshawks found elsewhere (Talbot et al. 2005 as cited in USFWS 2007). During the last decade, conservation designations of the goshawk in Southeast Alaska have varied; however, its status in Southeast Alaska remains a concern (Cotter 2007b). In addition to being considered a species of special management concern on the Tongass, the Queen Charlotte goshawk is of special concern to the State of Alaska and has been included by Stenhouse and Senner (2005) on Audubon's Alaska WatchList because of its limited distribution and the potential threats posed by commercial timber harvesting in breeding and nonbreeding seasons. In 2000, the Canadian government listed the Queen Charlotte subspecies as threatened because of continued logging of low-elevation, old-growth coniferous forests within its range and likely population declines (Environment Canada 2006).

Within Southeast Alaska and on the Tongass, the goshawk is a year-round resident and may occupy different, or overlapping, winter and breeding territories. Prior to studies during the past decade, very little was known about goshawks on the Tongass. Goshawks occur in low densities across the Forest and are difficult to study in the dense temperate rainforests of Southeast Alaska (Schempf et al. 1996 as cited in USFWS 2007). A recent interagency study of goshawks in the Tongass found 61 nesting areas within approximately 30,000 mi^2 (77,000 km^2); though this number is not reflective of a density estimate *per se* (Flatten et al. 2001). Goshawk nests can be found in all LUDs, and the number of known nest sites has not significantly increased in recent years; however, this is probably related to reduced survey efforts and the fact that goshawks are frequenty missed during surveys due to their secretive nature, low density, and use of old-growth habitats where they are difficult to detect (Flatten et al. 2001, Boyce et al. 2005, *Northern Goshawks on the Tongass National Forest* presented at the Tongass Conservation Strategy Review Workshop 2006). The interagency research project has also ceased, and follow-up of leads apart from timber sale activities now seldom occurs.

A nesting area, which in Southeast Alaska can be 2,000 acres (800 hectares) in size (Iverson et al.1996, Flatten et al. 2001), is defined as the area containing all nests used by a pair of goshawks; it is the portion of a pair's home range that contains all active and inactive nests. Female goshawks tend to move greater distances between nests in sequential years than males; however, a majority of nests remained within a 0.8-mile (1.3-kilometer) radius of the previous year's nest and all movements were within 3.2 kilometers of the "year one" nest site (Lewis and Flatten 2004 as cited in USFWS 2007). Adult home ranges on the Tongass are some of the largest recorded for the species, averaging 9,640 acres for females and 10,625 acres for males during the nesting season, and 29,160 acres for females and 29,400 acres for males outside of the nesting season (Lewis and Flatten 2004 as cited in USFWS 2007). The large size of Tongass goshawk home ranges compared to other areas may be related to methological differences; aircraft were used in Southeast Alaska for radiotelemetry and birds were located even if they were "over the ridge" where ground-based radiotelemetry would not have located the bird (Squires and Reynolds 1997, Kenward 2006).

Based on a recent study of 37 nest trees, 54 percent were Sitka spruce, 41 percent were western hemlock, and 4 percent were yellow cedar (Flatten et al. 2002). Lewis et al. (2003) found nest trees in Southeast Alaska to be larger than those around them at the nest site. In a separate analysis of 63 nest sites (habitat immediately surrounding the nest) from 50 nesting areas (a 20- to 30-acre area surrounding a nest, including roosts and prey plucking sites), 89 percent were located in high-volume stands with relatively dense, multi-storied canopies (SD5N, SD5S, and SD67 categories) compared to the surrounding forest (Lewis et al. 2003, McClaren 2004, Doyle 2006); nest areas had significantly more forest, productive forest, hemlock, and canopy cover and less non-forested area than random 12-hectare plots, and less non-forested habitat and forest/non-forest edge than random 65-hectare plots (Lewis 2005). Goshawk nesting density appears to be closely associated with dense overstories and open understories and goshawk habitat may therefore be improved by silvicultural activities which reduce the densities of shrubs, saplings, and small poles, while maintaining or enhancing the canopy of large trees (Crocker-Bedford 1990). Some nests have been found in maturing second-growth (previously harvested) stands (Bosakowski et al. 1999, McClaren 2004). On Vancouver Island, most second-growth stands supporting nests were 60 to 80 years old, and suitable structure was apparently achieved in as little as 50 years (McClaren 2004).

The diet of goshawks in Southeast Alaska is dominated by a few key prey (grouse spp., medium-sized birds such as Steller's jay and varied thrush, and red squirrels, where present). In prey rich areas, blue grouse and red squirrel are the dominant prey items taken (Lewis 2001). On Prince of Wales Island and other islands where blue grouse and red squirrels are not present, spruce grouse, Steller's jays, and ptarmigan are the dominant prey items taken (Lewis 2001). Small mammals make up a small portion of the overall diet in this area. Thrushes, grouse, and squirrels (common forest inhabitants that may be affected by timber harvesting) contribute up to 60 percent of prey deliveries to goshawk nests during the breeding season (Lewis et al. 2004). Recent research from neighboring populations on Haida Gwaii/Queen Charlotte Islands suggests blue grouse populations have probably declined since intensive harvesting was initiated, despite the limited benefit gained from some recent harvesting (e.g., new openings [more than 15 years] are used by breeding birds), and that this decrease in grouse may have substantially impacted the viability of the threatened goshawk population (Doyle 2004a, 2006).

POG forest is an important component of goshawk habitat use patterns in Southeast Alaska and at all scales (nest tree, nest site, post-fledging areas) goshawks select POG forest types. Habitat use of the 1,000-foot beach and estuary buffer was higher for females than males during the nesting and non-nesting season, with peaks in use occuring at 3,000 and 4,000 feet from the beach fringe (*Northern Goshawks on the Tongass National Forest* presented at the Tongass Conservation Strategy Review Workshop 2006). Radio telemetry points within adult home ranges suggest very high use of POG forests. Non-productive forest types and second-growth stands are also used to a lesser extent, and in some areas these matrix lands may be important for long-term goshawk management (Reynolds 2004, Reynolds et al. 1992). Most other habitat types (such as alpine, subalpine, muskeg, and clearcuts) were used infrequently or avoided by goshawks. This is corroborated by recent research conducted in the Southwest and Pacific Northwest, which indicates that although goshawks prefer to place their nests in mature to old-growth forest types, they are much more adaptable than once thought, and when these habitats are not available they will nest in maturing second growth with sufficient structure or in smaller patches of trees, and forage in young forest as well as along edges and in openings (Bosakowski et al. 1999, McClaren 2004, Boyce et al. 2006, Reynolds et al. 2006). Although there is some documented use of second growth in Southeast Alaska, the majority of Southeast Alaska second growth is younger than 50 years and most goshawks are associated with older forests. Use of older second growth (e.g., approximately 90- to 100-year-old stands) by goshawks for nesting in a few instances in Southeast Alaska was used by the assessment panels to suggest that goshawks would benefit from a long timber rotation of 150 or 200 years, providing 50 or 100 years of use.

Timber harvesting on the Tongass and on private lands in Southeast Alaska, has resulted in the conversion of old-growth forest to young growth, and likely has contributed to a decline in goshawk habitat capability due to their association with this habitat and the association of their prey with this habitat (e.g., blue grouse and red squirrels). Although goshawks are considered generalist predators and possess some adaptability to fluctuations in their prey base, large-scale habitat disturbance may diminish breeding success of goshawks in Southeast Alaska through changes in prey availability (Lewis et al. 2004). In the contiguous U.S., such habitat change is believed to reduce the number of breeding goshawks by degrading the structural character of forests used for nesting and foraging, though it is still unclear how goshawk populations respond to habitat modifications because study of effects across a gradient of harvest intensity is lacking (Boyce et al. 2006). However, forest harvest may be compatible with goshawk management provided that habitat needs are provided at multiple spatial scales (Reynolds et al. 1992). For example, Doyle (2004b) concluded that grouse selection of stands with more open canopy with a variety of heights and a patchy shrub layer on the Haida Gwaii/Queen Charlotte Islands, provides for the possibility that there may be a pattern for single tree selection, or a patch retention harvest threshold, that will allow harvesting without impacting grouse populations and thus, goshawks.

In 1996, a conservation assessment was conducted to synthesize literature and original data from Southeast Alaska to describe the habitat relationships and conservation status of the Queen Charlotte goshawk (Iverson et al. 1996). Iverson et al. (1996) concluded that goshawk habitat theoretically could be maintained across the landscape under a 300-year ecological rotation. A risk assessment using a conceptual 300-year rotation revealed that several landscapes (including the North Prince of Wales Biogeographic Province) within the Tongass may be at increased risk of not sustaining goshawks. The assessment suggested that a combination of reserve-based and dynamic-landscape management approaches could sustain well distributed viable populations of goshawks across the Tongass. In 1997, a panel of goshawk experts concluded that, even though they had viability concerns, under the 1997 Tongass Forest Plan, there would be a high likelihood that after full implementation for 100 years, goshawks would still persist across the Forest in some distributional status considerably more dense than in refugia (Iverson 1997).

As noted above under the Threatened and Endangered Species section, a recent court decision has required USFWS to determine whether Vancouver Island is a “significant portion of the subspecies range” and, if so, to determine whether the bird should be listed. USFWS (2007) finalized an update to the 1997 Status Assessment in April 2007. A new Finding, released in November 2007 concluded that that

Vancouver Island is a significant portion of the Queen Charlotte goshawk's range and that listing the subspecies on Vancouver Island is warranted. The review also indicated that the subspecies' populations in British Columbia and Alaska are DPS and that the best available information on biological vulnerability and threats to the goshawk does not support listing the Alaska DPS as threatened or endangered at this time.

Osprey

The best available information indicates that the osprey is naturally rare in Southeast Alaska and this area may represent the northern periphery of the species' range. A total of 16 osprey nest sites have been documented in Southeast Alaska (USDA Forest Service 1997a). Of this total, no more than three have ever been known to be active in any year. Nests can be found along the coasts of Wrangell Island and Kupreanof Island, typically 0.25 to 1.4 miles from the nearest saltwater; ospreys do nest along inland freshwater lakes, but none has been documented in Southeast Alaska. They require large trees and snags or power poles for nesting and, in Southeast Alaska, osprey nests typically occur in broken-top spruce trees or western hemlock snags. Ospreys nest from late April through August and probably overwinter in Mexico and Central America. Historically, there is no evidence that there were additional ospreys in Southeast Alaska, and population numbers have remained stable but low. Limiting factors are unknown, but available nest sites and foraging areas (i.e., larger lakes, rivers, beaver ponds, coastal beaches or large estuaries with abundant fish) do not appear to be limiting. Interaction and competition with the abundant bald eagle population may be a limiting factor.

Peale's Peregrine Falcon

As of 1997, 36 nests of Peale's peregrine falcon have been located in Southeast Alaska; 32 of which are on the Tongass National Forest. Nest surveys are very difficult to conduct, and biologists believe more nests may be present. Peregrine nest distribution is closely associated with large seabird colonies located on the outer coasts or nearby islands. The nest sites are on cliffs ranging from 65 to 900 feet in height; all but one nest faces the open ocean. Seabirds are thought to be major prey of the falcon. Information on falcon breeding biology or reproductive success is limited, but based on USFWS surveys, their population appears to be stable.

Trumpeter Swan

The largest nesting population of trumpeter swans on the Tongass National Forest occurs on the Yakutat Forelands. A smaller breeding population occurs in the Chilkat Valley on non-NFS land. Young cygnets have been located as far south as Traitors Cove on Revillagigedo Island and pairs of swans have been consistently observed during the summer months on Smuggler's Lake on the Cleveland Peninsula. Surveys by USFWS and other cooperating agencies indicate that the Yakutat population continues to be stable. A complete aerial survey was completed in September 2005. Mean brood size was estimated at 3.1 with approximately 27 percent of the total swans counted (n=23,692) reported as juveniles. The mean brood size was 3 percent higher than in 2004, but lower than the 29-year mean. The proportion of juveniles was 30 percent higher than in 2004 and 7 percent above the 29-year average. Trumpeter swans winter in ice-free areas throughout Southeast Alaska. Winter surveys on the Yakutat Forelands documented 646 adults and 98 juveniles in March 2006. Information on wintering habitats and populations elsewhere on the Tongass is very limited, but a traditional winter concentration area has been documented on Mitkof Island near Petersburg. Numerous swans from other parts of Alaska migrate through Southeast Alaska, and many winter in suitable habitats in Southeast Alaska.

Management Indicator Species

Management Indicator Species (MIS) are vertebrate or invertebrate species whose response to land management activities can be used to predict the likely response of other species with similar habitat requirements. NFMA regulations of 1982 require both the selection of MIS during development of forest plans (36 CFR 219.19(a), 1982), and that reasons for species selection be clearly stated. Criteria are to include those species whose population changes are believed to indicate the effects of management activities (36 CFR 219.19(a)(1), 1982).

Though required under the NFMA, the MIS concept is not universally accepted and is difficult to use, especially on the Tongass. First, our fundamental knowledge of many Tongass MIS is limited, as is our understanding of the viability requirements of most Tongass wildlife species. Moreover, although Tongass MIS represent varying needs related to old-growth forest, there is no assurance that all or even most other old growth associated species are adequately represented. Additionally, many current MIS are difficult to monitor or no clear linkage has been established between observed population changes and habitat modification. Some species may be better monitored through surrogate measures such as important habitat features or prey populations. Consequently, an effort is underway to re-evaluate, and possibly reduce, the current list of MIS.

For the 1997 Forest Plan, 13 wildlife MIS were identified and are discussed in this section. Four MIS species with special management concerns (brown bear, marten, Sitka black-tailed deer, and Alexander Archipelago wolf) are discussed in more detail. POG habitat provides essentially all of the highly important habitats and the preponderance of the moderately important habitats for most of the MIS. However, some species (e.g., wolves) use a variety of different habitats but rely on prey species associated with old growth (e.g., black-tailed deer). Table 3.10-2 indicates the relative importance of conifer successional stages as habitat for the MIS. Table 3.9-4 in the *Biodiversity* section displays the elevational distribution of productive and unproductive old growth on the Tongass, based on different elevation constraints thought important for many of the species discussed in this section.

Sitka Black-Tailed Deer

Sitka black-tailed deer (*Odocoileus hemionus sitkensis*) are indigenous to the coastal regions of Southeast Alaska and northwest British Columbia. This subspecies of mule deer occupies the northernmost extreme of black-tailed deer habitat. Deer are strong swimmers, and have occupied almost all islands of the Alexander Archipelago capable of supporting them. On the mainland, deep snow and harsh winters limit populations more than on the islands.

The Sitka black-tailed deer is the wildlife species receiving the highest hunting and subsistence use of all terrestrial species in Southeast Alaska. Table 3.10-7 in the effects section below presents the average deer harvest per year over the last 10 years by Wildlife Analysis Area (WAA). This species represents those that use lower elevation (below 800 feet elevation) POG forest habitats during the winter period. The quantity, quality, distribution and arrangement of winter habitat are considered the most important limiting factors for Sitka black-tailed deer in Southeast Alaska. There are about 4.8 million acres of old-growth forest (3.0 million acres of POG and 1.8 million acres of unproductive old growth below 800 feet elevation within occupied deer habitat on the Tongass National Forest (Table 3.9-4 in the *Biodiversity* section). Currently, approximately 92 percent of the original old growth remains Forest-wide (see Table 3.10-7 for relative deer habitat capability by WAA).

Table 3.10-2
Relative Importance of Conifer Successional Stages as Habitats for Management Indicator Species

		Successional Stages[1]					
					Late (>200 years)		
		Early (years)	Mid (years)			Productive Old Growth	
Species	Season[2]	0-25	26-150	150-200	Unproductive Old Growth	Low-Med (SD4S, SD4N, SD5H)	High (SD5S, SD5N, SD67)

Van. Can. Goose	2,3	L	L	L	H	H	H

[1] H = Highest importance, high population densities, M = Moderate importance, moderate population densities, L = Least importance, low population densities
[2] Season codes: 1 = winter, 2 = spring, 3 = summer, 4 = fall, 5 = all year
[3] Wolves use habitats according to the abundance and availability of prey species (primarily Sitka black-tailed deer).

A deer winter habitat suitability index (HSI) model, which takes into account snow depth (indicative of typical, moderate winter severity), elevation, aspect, and conifer forest successional stage, is currently used in Tongass Forest planning to provide an index of habitat capability (referred to as the TLMP deer model, DeGayner 1997). It is a stand-alone model, based on expert opinion, which does not require the collection of new data. Old-growth forests are assigned the highest value because they intercept snow and provide understory forage plants. Generated HSI values are an index of how features are correlated with deer winter habitat. High model scores represent features that are correlated with deer abundance. These features include closed canopy (based on volume class rather than canopy cover), maritime influence, south facing slopes, and low average snow depth.

One shortcoming of the model is the high rating it gives to some large-tree old-growth stands (some of the stands mapped as SD67). These stands consist of widely spaced, very large Sitka spruce trees, most commonly located in riparian floodplains. Riparian floodplains tend to be some of the coldest locations on the landscape due to cold air drainage, shade, and flat terrain, and tend to have greater snow accumulations than neighboring stands, making them less hospitable to deer (T. Hanley, personal communication, 2007). Additionally, despite their high volume, these stands have open overstories that intercept less snow than other stands and, while they typically have a high understory biomass, dominant species include devils club, salmonberry, elderberry, and ferns, all of which provide suitable forage during summer but not during winter (Hanley and Hoel 1996). Thus, these stands constitue poor winter range, but by default, their high volume results in high assigned model values. The effect of this error is to overestimate the value of some large tree stands and to overestimate the impact of their harvest; however, the overall effect is relatively small because these stands comprise a very small fraction of the landscape (T. Hanley, personal communication, 2007).

Recent research indicates the greater importance of summer range for reproduction and population recovery following severe winters, and for building up pre-winter body reserves. This suggests that changes to the 1997 HSI model may be warranted such that higher suitability values are assigned to habitats that provide important summer forage, such as recent clearcuts, unproductive forest, and low volume old growth (Parker et al. 1999). Due to changes in vegetation mapping on the Tongass, model coefficients are currently being refined; however, these modifications will occur outside of the timeframe for the Forest Plan amendment. Therefore, the existing, approved deer HSI model used in the 1997 Forest Plan Revision Final EIS will be used here for alternative comparisons, with the caveat that it likely overestimates the effect of timber harvest on deer habitat quality.

The deer model provides a tool to evaluate the relative differences among alternatives. The winter HSI model is most appropriate for analysis over large planning areas such as the entire Tongass National Forest or at the scale of a WAA or number of WAAs, where the greatest differences in habitat value occur between main habitat types (e.g., old growth versus young clearcuts versus closed-canopy young-growth) and their topographic settings, rather than differences within such classes. Thus, the model has limitations when applied at the watershed or project planning level. A new tool for evaluating deer habitat appropriate for analysis at finer scales, called the Forest Resource Evaluation System for Habitat (FRESH-Deer) model, is currently being developed by the Forest Service in cooperation with the University of Alaska (*Deer Habitat Management*, presented at the Tongass Conservation Strategy Review Workshop 2006). FRESH-Deer is a food-based system that provides a “snap shot” analysis of habitat conditions at one point in time by taking into account the biomass of available forages (by species and by plant part), the nutritional quality of each forage (e.g., digestible energy and digestible protein), and user-specified metabolic requirements (e.g., metabolic energy, digestible protein) that are dependent on the age, sex, season, and reproductive status of the animal. The model identifies limiting factors within the habitat and the most important forages. In contrast to the winter HSI model, FRESH-Deer is a data-driven model that requires the collection of new data. In the future, this model may be available for use in project planning.

In addition to winter habitat conditions, predation can act as a major controlling factor of deer populations. Primary predators include humans, wolves, and black-bears; however, the predominance of each in terms of impacting the deer population varies geographically. For example, studies of deer mortality indicate that on Mitkof and Heceta Islands human harvest and wolf predation were the main causes of deer mortality, but on Prince of Wales Island deer mortality (primarily fawns) was predominantly due to bear predation (*Wolves and Predator-Prey Interactions*, presented at the Tongass Conservation Strategy Review Workshop 2006). Deer are the primary prey of wolves in Southeast Alaska, and the significance of predator/prey interactions on wolf populations led to the conclusion that wolf persistence was directly linked to deer habitat capability. However, even in high-quality habitats increased deer mortality can occur during severe winters. In fragmented landscapes, where small, remnant patches of old growth exist, deep snow may isolate deer by precluding movement between patches (McNay 1995). Concentrated use of these areas can result in overbrowsing of forage and ultimately malnutrition and death (Farmer et al. 2006)

Mountain Goat

Mountain goats (*Oreamnos americanus*) represent species using cliffs, alpine and subalpine, and old-growth forest habitats. The quantity and quality of winter habitat is the most limiting factor for mountain goats in Southeast Alaska. Lack of snow interception in early successional stages and lack of forage in middle successional stages reduces the value of winter habitat. Historically, mountain goats in Southeast

Alaska were present only on the mainland, but they have more recently been transplanted to many of the islands.

Mountain goat populations in Southeast Alaska are currently monitored via ADF&G aerial surveys and harvest records, which are used to estimate population trends. This species is considered one of the easier species in Southeast Alaska to monitor by virtue of their predictable use of open terrain during summer and fall. However, they spend much of their time outside of areas where habitat manipulations (e.g., logging) have occurred or are likely to take place in the future. Additionally, a clear link between timber harvest and mountain goat population trends has not been established. Existing Forest Plan standards and guidelines were developed to reduce the impacts of other activities (e.g., helicopter over-flights) and impacts associated with facilities (e.g., crew camps).

Black Bear

Black bears (*Ursus americanus*) are present throughout the mainland and on the islands south of Frederick Sound. They use habitats from sea level to the alpine. There are about 9.4 million acres (excluding rock, permanent ice fields, and acres of lakes) within occupied black bear range on the Tongass National Forest. Estuarine, riparian, and forested coastal habitats receive the highest use by black bears and appear to have the highest habitat values. Within forested areas, both early and late (old growth) successional stages provide the best forage and/or cover for black bears. A recent interagency study estimated black bear population size on the northern portion of Kuiu Island (Peacock 2005) and conservation genetics more broadly across the Alexander Archipelago (e.g., Peacock et al. 2007).

Black bears were chosen as an MIS because of their importance for hunting and for recreation and tourism. However, this species is difficult to monitor and existing monitoring data, derived from ADF&G sealing records, are not sensitive enough to detect population changes over large expanses, or determine the cause of population change in a given area.

River Otter

The river otter (*Lutra canadensis*) was selected as an MIS because of its association with coastal and freshwater aquatic environments and the immediately adjacent (within 100 to 500 feet) upland habitats. River otters are distributed throughout Southeast Alaska along coastal and inland waters (MacDonald and Cook 1999). Their distribution is Forest-wide in suitable habitats. Beach characteristics affect the availability of food and cover, and adjacent upland vegetation is also important in providing cover for otters. Old-growth forests have the highest habitat value, providing canopy cover, large-diameter trees and snags, and burrow and den sites. They tend to use POG (SDM SD5N, SD5S, SD67 categories) with fairly open understory and greater than 50 percent canopy closure where they commonly rest in cavities or beneath the roots of large conifers or snags (Larsen 1984, Ben-David et al. 1996, Bowyer et al. 2003). Younger successional stages provide lower quality habitat.

The best data currently available on river otter populations typically consist of infrequent, localized density estimates and thus may not be sufficient to monitor population changes at a level of resolution appropriate for the Tongass National Forest (i.e., commensurate with very small changes in habitat). Further, there is no monitoring protocol in place to detect changes in the population due to human-caused habitat change. Beach, Estuary, and Riparian standards and guidelines under the current Forest Plan protect most, if not all, of the key otter habitat components, thus greatly reducing risk to this species and others that rely on such habitats. It is important to note, however, that most streams receive a standard 100-foot buffer which does not protect habitat used by otters beyond this distance.

American Marten

Marten naturally inhabit the mainland of Southeast Alaska and many of the islands in the Alexander Archipelago. Known endemic populations exist on Admiralty, Etolin, Gravina, Kupreanof, Mitkof, Revillagigedo, Woewodski, Wrangell, and Kuiu Islands (MacDonald and Cook 2000). However, many islands remain unsampled but could also support populations. Marten were transplanted to Prince of Wales, Chichagof, and Baranof Islands between 1930 and 1950; whether these transplants were new introductions or just supplemented existing populations is unknown.

Although only one species of marten is formally recognized in Southeast Alaska two distinct lineages exist, including the coastal form *caurina,* which in the Alexander Archipelago occurs only on Kuiu and Admiralty Islands, and the continental form *americana* (Cook et al. 2006). Originally, these lineages were described as separate species but were reclassified as separate subspecies in the 1950s. It is unknown whether these lineages have different life history traits or habitat preferences, and thus, may require different management strategies. However, recent molecular analyses clearly distinguish the two forms and suggest that they have very different evolutionary histories (Stone and Cook 2002, Small et al. 2003, Cook et al. 2006). Hybridization of *caurina* and *americana* individuals has been documented in the two contact zones where both forms coincide, one in Southeast Alaska (Kuiu Island) and one in Montana (Cook et al. 2006).

Marten numbers fluctuate greatly over time in response to food availability habitat conditions and trapping pressure. Results of a multi-scaled study on Chichagof Island conducted between 1990 and 1999 evaluated marten habitat selection, demographics, diet, and prey availability, and indicate that marten abundance is best predicted by the abundance of long-tailed voles (Flynn and Schumacher 2001, Flynn et al. 2004). Habitat requirements reflect a strong interaction between food, cover, climate, and predation, with forest cover being particularly important for travel, dens and resting sites, hunting, and avoiding predation and inclement weather (Flynn and Schumacher 1999, 2001). Consequently, the quantity and quality of winter habitat is a limiting factor for marten in Southeast Alaska. There are about 7.2 million acres of forested land (all age classes and types of conifer forests) below 1,500 feet elevation within occupied marten habitat on the Tongass. Due to lower snow accumulation, habitats at lower elevations have higher value for wintering marten. Coastal habitats (beach fringe) and riparian areas have the highest value, followed by upland habitats below 1,500 feet in elevation. Of the successional stages, larger-sized old-growth forests have the highest value because they intercept snow, provide cover and denning sites, and provide habitat for prey species used by marten. Early successional stages do not provide these habitat components and have lower habitat value. However, studies of eight marten populations in Southeast Alaska conducted between 2001 and 2003 show that marten selected POG but used some second growth 26 to 40 years of age; on Mitkof Island these second growth stands were characterized by abundant understory forage and small mammals (Flynn et al. 2004). In addition, home ranges of marten were well distributed across the landscape and included areas with timber harvest and roads. These findings indicate that although OGRs are still an appropriate model for marten conservation in terms of providing optimal habitat requirements, the management of matrix lands to provide productive habitat and linkages between reserves is also important. Noteably, marten densities are higher in intact forests with less fragmentation (Hargis et al. 1999, Flynn et al. 2004), indicating that large, continguous block of old growth are important for this species.

Dispersal between islands is limited, but marten are fairly mobile on land. Marten are easily trapped and can be overharvested. Forest management activities resulting in increasing access may result in the potential for overtrapping. Currently the ADF&G permits unlimited trapping of marten in the Game Management Units (GMUs) that cover the Tongass (GMUs 1, 2, 3, 4, and 5) from December 1 to February 15. In GMU 3, which includes the endemic population on Kuiu Island, a 9-year average of 188 marten were trapped per year (Lowell 2004). For perspective, across Southeast Alaska the annual average harvest ranged from 224 martens per year on north central Prince of Wales Island to three martens per year on northern Kuiu Island between 1991 and 2002 (Flynn et al. 2004).

Marten were initially selected as an MIS because forest management activities were expected to affect population abundance, and marten pelts represented significant economic value to local residents. In Southeast Alaska, the best available information that can be related to marten populations comes from the ADF&G sealing records; however, this monitoring method was not designed to determine causes of observed population trends. Further, although marten populations appear to be sensitive to habitat alteration, no clear correlation between population trends and habitat change has been defined due to the lack of research on this dynamic and the absence of long-term population datasets. An assumption of the conservation strategy was that large OGRs would support a minimum of 25 female martens; however, in a study of marten densities conducted between 2001 and 2003, Flynn et al. (2004) determined that this minumim number was not met in five of eight study areas, the exception being the Chichagof Island site and possibly the sites near Point Couverden and Thomas Bay. These results illustrate the importance of the matrix lands between reserves for marten survival and the importance of the POG retention requirement under the conservation strategy.

Brown Bear

Southeast Alaska is home to one of the highest concentrations of brown bears (*Ursus arctos*) in the world (ADF&G 2000). Brown bears are important both for hunting (including both outfitter guided and non-guided hunting) and to the recreation and tourism industry of Southeast Alaska. As tourism grows in Southeast Alaska, there is increasing demand for more bear viewing opportunities such as those provided by Pack Creek and Anan Creek. Brown bears are present on the mainland and on most the islands north of Frederick Sound. They are occasionally reported on Mitkof, Etolin, and Wrangell Islands south of Frederick Sound, but are not found on any of the other islands in Southeast Alaska. Brown bears use areas from sea level to the alpine and are habitat generalists. There are about 7.9 million acres (excluding rock, permanent ice fields, and acres of lakes) within occupied brown bear habitat on the Tongass; 7.5 million acres of which are considered to be roadless. Home ranges of brown bears in Southeast Alaska are much smaller than those found in interior portions of North America. Average annual home range sizes for radio-collared bears on Admiralty Island was 39 square mile (100 square kilometers) and 14 square miles (37 square kilometers) for males and females, respectively (Schoen and Beier 1990); these are comparable to home range sizes of radio-collared bears on Chichagof Island (Titus et al. 1999).

The late-summer season has been identified as the most critical or limiting period for brown bears when they must build up energy reserves that are adequate to survive the winter and successfully reproduce (Hildebrand et al. 1999). During this season, many brown bears concentrate along low elevation valley bottoms and salmon streams, with most use occurring within 500 feet of streams (Schoen and Beier 1990, Titus and Beier 1999), where their efforts focus on consuming large quantities of fish in order rebuild their body condition and lay on essential fat reserves. Brown bears have been known to maximize their energy intake by preferentially attacking salmon with the highest energy content (i.e., those that have just entered the stream with protein and fat stores that have not yet been depleted) and by consuming the most energy dense body parts (Gende et al. 2004a, b, Gende and Quinn 2004). These are often the same areas of highest human use and most intense resource development activities. To better understand these relationships, a study on Chichagof Island conducted between 2001 and the present is evaluating brown bear spatial relationships, resource selection, and levels of use during the salmon spawning season in relation to riparian management along two drainages that differ in timber harvest intensity and road building (Flynn et al. 2007). Results showed that in both drainages male brown bears tended to concentrate their use along the stream, whereas females made greater daily movements and used both riparian and adjacent upland areas. In the drainage with more timber harvest and roading, with a smaller riparian buffer, daily movements of female bears tended to be greater and more variable (75 percent of radiotelemetry locations occurring within 2,482 feet of the stream), including more use of adjacent upland areas, than in the less disturbed drainage (75 percent of radiotelemetry locations occurring within 937 feet of the stream). DNA-based population estimates indicated that the number of male bears along both streams was approximately equal and remained constant over time, with an increase in use in September; the number of female bears present declined over the same period. Additionally, diet analyses were conducted with an interest in evaluating the proportion of the diet consisting of salmon, based on the premise that a greater amount of salmon in the diet should support a larger and more productive population. Salmon obtained from mid-summer to early fall represent an important food source for accumulation of energy reserves to sustain bears over-wintering in dens. Results showed that females along heavily managed streams ate less salmon than females along steams with larger riparian buffers, though both drainages still supported high densities of brown bears (22 bears per square kilometer in the less altered watershed and 13 bears per square kilometer in the highly altered watershed, as measured within a 500 meter riparian buffer). A similar study on the Kenai Peninsula reported that female brown bears with cubs tended to avoid areas used by other bears and by humans, apparently in an effort to increase offspring survival, and used less productive salmon spawning areas despite having high nutritional requirements (Suring et al. 2006). These results indicate that small streams are important for female and young bears and forested buffers are important to maintaining high density brown bear populations by providing adequate vegetative cover for secure foraging areas and to support anadromous fish production (Flynn et al. 2007).

Cover for visual obscurity, provided by riparian buffers, is important for minimizing interactions among bears and between humans and bears. Increases in human activity due to an expanding road system in an area may result in increased direct human-induced deaths of bears. This may include legal hunting, illegal kills, wounding losses, and deaths due to the defense of life or property (DLP mortality). Open roads are of greatest concern because they receive the highest, most consistent use; however, closed roads are also important to consider because they provide off-highway vehicle and pedestrian access. ADF&G permits harvest of brown bears in GMU 4, which encompasses Admiralty, Baranof, and Chichagof islands. An annual average of 165 brown bears per year was taken from this area over the last 5 years (ADF&G 2005b). Hunting is also permitted elsewhere in Southeast Alaska.

Alexander Archipelago Wolf

Two Alaskan subspecies of the gray wolf are currently recognized (Weckworth et al. 2005). The wolf found in Southeast Alaska is known as the Alexander Archipelago wolf (*Canis lupus ligoni*). It inhabits the mainland and the larger islands south of Frederick Sound (MacDonald and Cook 2000). However only the largest islands, including Prince of Wales, Kuiu, Kupreanof, Mitkof, Etolin, Revillagigedo, Kosciusko, Zarembo, and Dall islands, are thought to support persistent wolf populations (Person et al. 1996). Recent genetic analyses have shown that wolves on Prince of Wales Island (GMU 2) are a population segment isolated from all other wolves in Southeast Alaska and coastal British Columbia (Weckworth et al. 2005). Wolves require an adequate prey base of ungulates, beaver, and salmon; in most areas of Southeast Alaska the Alexander Archipelago wolf depends heavily on deer. Suitable habitats for wolves equate to areas capable of supporting this prey base. Wolves use a wide variety of habitats when prey are present, and can affect prey populations in those areas.

Wolf densities are closely tied to the population levels of their prey though populations may not exceed certain levels even when prey abundance is high due to other regulatory mechanisms including environmental conditions and social interatcions (Messier 1994, 1995). However, deciphering the influence of each of these factors can be obscured by varying rates of harvest, time lags in carnivore response to changes in prey, or changes in prey vulnerability (Peterson 1977, Fuller and Sievert 2001). Throughout their range, a density of one adult wolf per 10 square miles appears to be high, based on densities reported for wolf populations elsewhere in North America, and this density is often considered as a saturation point beyond which wolf populations would not expand (Person et al. 1996). Wolves have large home ranges (about 100 square miles per pack), use a wide variety of habitats, and are very mobile (Person et al. 1996).

A petition to list the Alexander Archipelago wolf as threatened under the ESA in 1993 illustrated a concern for the viability of this subspecies. USFWS accepted the petition, confirming the concern, but concluded in 1995 that listing was not warranted at this time. However, an interagency wolf conservation assessment was conducted to synthesize available information on wolf ecology and identify management considerations for sustaining viable wolf populations on the Tongass (Person et al. 1996). The assessment concluded that wolf densities are generally lower on the mainland and higher on islands in the southern half of the Tongass.

The large islands south of Frederick Sound (GMUs 2 and 3) support approximately 60 to 70 percent of the total wolf population in Southeast Alaska (Person et al. 1996, Person 2001). Principal concerns exist on Prince of Wales and Kosciusko Islands, where past timber harvest has reduced deer habitat capability and increased road density. Although the wolf population is capable of sustaining harvest, Person (2001) expressed concern that expanding road access, particularly on Prince of Wales Island, may increase mortality of wolves there beyond sustainable levels. Therefore, assessing potential impacts to the wolf population is critical given the complex relationship they have with deer populations and human livelihoods.

Recent analyses presented at the Tongass Conservation Strategy Review Workshop (2006) have modeled the probability of an overkill (average harvest of greater than 30 percent of the population) or destructive harvest (harvest greater than 90 percent of the population occurring once between 1985 and 1999) of the wolf population on Prince of Wales Island taking into account road density and whether the road system was connected to a main road system with access to a ferry. Results indicated that 32 percent of WAAs on Prince of Wales Island have road densities indicatative of a high probability of overkill and 52 percent have road densities indicating a high proability of having had at least one destructive harvest between 1985 and 1999. These results indicated that roads exert a strong influence on wolf mortality, particularly when connected to main road systems. However, it is important to note that roads themselves do not decrease habitat capability for wolves, but increased density of roads may lead to higher hunting and trapping mortality through improved human access. There are other methods available to address unsustainable hunting and trapping mortality including changes to both state and federal hunting and trapping regulations and increased enforcement.

GMUs 2 and 3 support some of the highest wolf densities in the state and populations are thought to be stable in GMU 2 and increasing in GMU 3 (ADF&G 2003). The State permits wolf harvest with a bag limit of five wolves taken by hunting and no limit for trapping; their objective is to maintain an average annual harvest of 39 wolves in GMU 2 based on the average harvest from 1984 to 1990 (ADF&G 2003). However, there is a harvest cap in GMU 2 that does not allow the harvest of more than 30 percent of the estimated fall population to ensure that a sustainable wolf population is maintained. Wolf hunting and trapping regulations for federally qualified users under the auspices of the Federal Subsistence Board are generally the same as that under State of Alaska regulation.

Important components of a wolf conservation strategy include providing core habitats with low road density, maintaining wolf harvest within sustainable limits through regulations, and providing adequate deer habitat to support an abundant and stable deer population. Under the current Forest Plan, this is accomplished through standards and guidelines for road density, deer density, and den site buffers with associated timing restrictions. Current wolf standards and guidelines direct that effective road closures should be implemented when road access has been determined through analysis to be a significant factor in wolf mortality contributing to unusustainable wolf mortality. Preliminary results presented at the Tongass Conservation Strategy Review Workshop (2006) indicate that closed roads also may contribute to wolf mortality and that open and closed roads should be considered in road density calculations. In addition, consideration should be given to excluding high elevations when calculating road densities. Current standards and guidelines related to den site buffers and timing restrictions include buffers of 1,200 feet surrounding active dens from April 15 to July 1, no road construction within 600 feet during this time period, and protection for active dens from disturbance.

The wolf was selected as an MIS because of population viability concerns in some areas of the Tongass. However, the datasets available for monitoring wolves are insufficient for detecting all but very large changes in the wolf population and are not designed to track trends in the population resulting from changes in their habitat. Additionally, although recent efforts have been made to improve information on wolves in the form of multi-year research projects undertaken by ADF&G and the Forest Service, it is difficult to determine the link, if any, between habitat change on the Tongass and changes in the wolf population, especially given confounding factors such as weather-dependent fluctuations in prey abundance or spatially differential hunting pressure (USDA Forest Service 2004i). Further existing observation and monitoring measures do not address the distinct population in GMU 2.

Bald Eagle

North America's bald eagle (*Haliaeetus leucocephalus*) population reaches its highest density in Southeast Alaska. In 1992 the population was estimated at over 13,000 adult birds; more than 8,000 nest sites were identified through 1996. Their nesting habitat is primarily old-growth trees along the coast and within riparian areas. The USFWS and Forest Service maintain an interagency agreement for bald eagle habitat management in the Alaska Region, which includes standards and guidelines for regulating human disturbance within identified bald eagle use areas.

Gende et al. (1998) reported a decrease in active bald eagle nest density with increasing proximity to clearcuts, with reduced nesting activity for locations within 948 feet (300 meters) of clearcuts. Gende et al. (1998) suggested that a buffer of 328 feet would be inadequate to mitigate effects of harvest, and recommended a

984-foot buffer around active nests (Gende et al. 1998). Furthermore, most bald eagles nest within 328 feet (100 meters) of saltwater shorelines in Southeast Alaska and it has been suggested that to prevent loss of this segment of the eagle population, a 1,300-foot buffer be maintained to protect all nesting bald eagles. Currently, a 330-foot radius protective habitat management zone surrounds all identified bald eagle nest trees and a 1,000 foot beach buffer is maintained along the shoreline.

The bald eagle was selected as an MIS because of its use of coastal areas for foraging and nesting. Unlike many current MIS, a reasonably precise estimate of bald eagle population trends in Southeast Alaska can be derived from surveys conducted by USFWS, which could serve as a logical measure of the efficacy of the 1,000-foot beach buffer prescription under the current Forest Plan. USFWS has completed an evaluation of the effectiveness of the 1,000-foot beach buffer prescription for conserving forest-dwelling birds through two separate research projects, which indicated that a minimum of 1,000-foot buffer was beneficial for several species (red breasted sapsucker and some others) and then buffers less than this may not be effective at maintaining nesting habitat for some species (see Kissling 2003 and Sperry 2006 for additional information).

Red Squirrel

The red squirrel is one of only two arboreal rodents in Southeast Alaska. Red squirrels are abundant on many of the islands in the Alexander Archipelago and the mainland. Red squirrels require forests with cone-producing trees and cavities in trees and snags for nesting and denning. The root systems of large spruce trees are also important for den sites. They represent a species that can do fairly well in seed-producing young-growth timber stands. There are about 8.4 million acres of forested land (including all age classes and types of conifer forests) within occupied red squirrel habitat on the Tongass National Forest. Optimum habitat use is believed to occur when patches of preferred habitat are greater than 30 acres.

The red squirrel was selected as an MIS because it is an important prey species for marten and requires forests with cone-producing trees and cavities in trees and snags. However, few data are available describing red squirrel populations over time and changes in local populations do not necessarily imply negative impacts to the overall population. Thus, this presents an impasse in the ability to correlate human-induced habitat change with population trends. Additionally, although habitat capability for red squirrels is reduced through the conversion of POG to second growth, recovery of habitat capability after timber harvest is much faster for red squirrels than other species. That is, although post-harvest formation of structures favored for nesting and food storage (cavities) takes longer, the majority of habitat capability (food availability) is restored quickly as cone production typically begins 40 years after harvest.

Red-breasted Sapsucker

The red-breasted sapsucker (*Sphyrapicus ruber*) is well distributed throughout Southeast Alaska during the spring, summer, and early fall seasons, and occurs in lower elevations during the late fall and winter seasons. They use a wide variety of forested habitats but require the presence of snags during the breeding season and are indicative of low volume POG (SD4H category). They are weak excavators and therefore require rotted or soft substrates in order to create cavities for nesting and roosting. There are about 9.9 million acres of forested land (includes all age classes and types of conifer forests) within occupied red-breasted sapsucker habitat on the Tongass National Forest of which approximately 980,000 acres are in the SD4H category (see Table 3.9-5 in the *Biodiversity* section). Old-growth forests provide the best snag habitat over the long-term; stands with higher densities of snags receive more use. Red-breasted sapsuckers on northern Vancouver Island, British Columbia, preferentially selected large diameter trees (mean diameter at breast height [dbh] 93.3 cm), which Joy (2000) surmised provided an optimal balance of nest space (could accommodate larger clutch sizes), insulation, and protection from predation. In managed landscapes, forest buffers are important for this species. Kissling (2003) found that in Southeast Alaska red-breasted sapsucker densities were positively correlated with forest buffer width, and appeared to be maximized when bufferes were at least 300 meters wide.

The red-breasted sapsucker was selected as an MIS as a representative primary cavity excavator. In Southeast Alaska, currently the best available information that can be related to red-breasted sapsucker populations comes from the US Geological Survey (USGS) Breeding Bird Survey (BBS) and the Audubon Society Christmas Bird Counts (CBC). Additional information has been derived from the Monitoring Avian Productivity and Survivorship (MAPS) program, under which three to seven stations are surveyed by the Tongass National Forest to capture forest birds during the breeding season, and the Alaska Landbird Monitoring Survey (ALMS). However, these are large-scale monitoring programs and may not detect changes in avian populations at a scale and resolution appropriate for the Tongass National Forest. Further, existing monitoring does not relate changes in red-breasted sapsucker habitat directly to changes in their populations under the present limitations of data provided and assumptions used.

Hairy Woodpecker

The hairy woodpecker (*Picoides villosus*) is considered an uncommon, permanent resident throughout Southeast Alaska. Hairy woodpeckers use old-growth forest habitats with snags and dying trees for foraging and nesting. Like the red-breasted sapsucker, hairy woodpeckers are primary cavity excavators for other cavity-using wildlife species. Their winter habitat may be their most limiting. There are about 9.9 million acres of forested land (including all age classes and types of conifer forests) within occupied hairy woodpecker habitat on the Forest. High-volume old-growth forests provide the best long-term snag habitat, with large diameter old-growth trees (particularly SD5S, SD5N, and SD67 categories) receiving more use than stands with smaller diameter trees. There are approximately 2 million acres of old growth in the SD5S, SD5N, and SD67 categories; optimum habitat use is believed to occur when patches of preferred habitat are greater than 500 acres.

The hairy woodpecker was also selected as an MIS as a representative primary cavity excavator. As with the red-breasted sapsucker, the best available information that can be related to hairy woodpecker populations in Southeast Alaska comes from the BBS, CBC, the MAPS program, and the ALMS. However, these are large scale monitoring programs and may not detect changes in avian populations at a scale and resolution appropriate for the Tongass National Forest. Further, existing monitoring does not relate changes in hairy woodpecker habitat directly to changes in their populations under the present limitations of data provided and assumptions used.

Brown Creeper

The brown creeper (*Certhia americana*) is considered an uncommon, permanent resident throughout Southeast Alaska. Brown creepers are likely more common than usually acknowledged, but detectability of this species is relatively low, resulting in abundance estimates that are biased low. This species was selected as an MIS because of its close association with large diameter old-growth trees (particularly SD5S, SD5N, and SD67 categories). As noted above, there are approximately 2 million acres of the SD5S, SD5N, and SD67 category old growth on the Forest. The factor most cited as limiting brown creeper populations is the availability of old-growth and mature woodlands as nesting and foraging sites and research has shown that creepers abandon sites that have been subjected to even light (e.g., partial-cut) logging activity because such activity is typically focused on large, mature trees (Wiggins 2005). In a study of the effects of buffer width on breeding bird communities in the Tongass, a majority (83 percent) of all brown creeper observations occurred in undisturbed control plots (Kissling 2003). Optimum habitat use is believed to occur when patches of preferred habitat are greater than 15 acres (USDA Forest Service 2003).

In Southeast Alaska, the best available information that can be related to brown creeper populations comes from the BBS and the CBC. Additional information has been derived from the MAPS program and the ALMS. However, these are large scale monitoring programs and may not detect changes in avian populations at a scale and resolution appropriate for the Tongass National Forest. Further, existing monitoring does not relate changes in brown creeper habitat directly to changes in their populations under the present limitations of data provided and assumptions used.

Vancouver Canada Goose

Vancouver Canada geese (*Branta canadensis*) are distributed throughout the Alexander Archipelago of Southeast Alaska, with an estimated resident population of 10,000 birds. This population is relatively non-migratory, with the majority of birds moving only locally between nesting, brood rearing, molting, and winter concentration areas. Vancouver Canada geese were selected as an MIS because of their association with wetlands (both forested and non-forested) in the estuary, riparian, and upland areas of the Forest. Vancouver Canada geese are highly mobile and are found throughout the islands of Southeast Alaska.

Nesting and brood-rearing habitats are potentially affected by various forest management activities, though timber harvest in these areas has generally been minimal because these sites are fairly unproductive. Additionally, Riparian and Wetland standards and guidelines in place under the current Forest Plan, which include the use of various Best Management Practices (BMPs), are designed to minimize impacts to and maintain the function of these habitats. Effects of timber harvest and recreation on winter habitats have not been assessed but may result in increased human disturbance to wintering flocks or their habitats. Waterfowl census surveys conducted by the USFWS are the best source of demographic information for Vancouver Canada geese; however, population data are too insufficient to indicate a Forest-wide trend in the population, and thus no clear relationship has been established between population numbers and trends in habitat change.

Other Species of Concern

Marbled Murrelet

The marbled murrelet (*Brachyramphus marmoratus*) is a robin-sized seabird. It feeds below the water's surface on small fish and invertebrates, and in Southeast Alaska, is usually found within 5 miles of shore. The marbled murrelet typically nests on mossy-limbed branches of large, mature coniferous trees within stands of structurally complex, coastal old-growth forest (SD5N, SD5S, SD67 categories). There are roughly two million acres of this habitat on the Tongass. However, on some treeless islands in Southeast Alaska marbled murrelets will lay eggs on bare talus slopes in mountainous areas (Piatt et al. 2007).

The majority of the world population of marbled murrelet breeds in Alaska, with most found in Southcentral and Southeast Alaska. In March 2006, a status review for the marbled murret was initiated by the USFWS for the northern part of the species range to support ESA deliberations over the listing of the species as threatened in the sourthern part of its range (California, Oregon, and Washington). This review compiled published information on the conservation status, population biology, foraging ecology, population genetics, population status and trends, demography, marine and nesting habitat characteristics, threats, and ongoing conservation efforts for marbled murrelets in Alaska and British Columbia (Piatt et al. 2007). Genetic analysis conducted as part of the review identified three distinct population segments: one in the central and western Aleutian Islands, one ranging from the eastern Aleutians to Northern California, and one in central California. Based on historical abundance information, the Alaska population numbered approximately 1 million birds in the recent past and is now estimated to be approximatey 270,000 birds (Piatt et al. 2007). Three areas of greatest abundance include Lower Cook Inlet (35,670 birds), Prince William Sound (33,745 birds), and Southeast Alaska (144,190 birds).

Using trend information from at-sea surveys conducted at eight sites in Alaska, numbers have declined annually at five sites at rates of -5.4 to -12.7 percent per year since the 1990s, representing an overall decline in the Alaska population of 70 percent during the past 25 years (Piatt et al. 2007). Populations at three sites in Southeast Alaska have exhibited overall declines of 46 to 70 percent between the early 1990s and 2001. Likewise, the Prince William Sound population declined by 69 percent between 1989 and 2005 and the population on the outer coast has declined by 43 percent between 1992 and 2002. Possible causes of estimated overall Alaska declines are oil spills, mortality from gill netting, cyclic changes in marine food productivity, and the harvesting of POG forests, though it is likely that it is a combination of these forces, as has been implicated in similar declines observed in other seabird populations in Alaska (Piatt et al. 2007). The 2007 status review concluded that, over the last half century, marbled murrelets have lost about 15 percent of their suitable forested nesting habitat in Southeast Alaska due to large-scale logging, though nesting habitat losses cannot explain the declines observed in areas such as Prince William Sound or Glacier Bay where industrial logging has not occurred on a large scale or at all (Piatt et al. 2007).

Recent research indicates that key microhabitat characteristics of marbled murrelets nest sites include: (1) sufficient height to allow stall landings and jump-off departures, (2) openings in the canopy for unobstructed flight access, (3) sufficient platform diameter to provide a nest sight and landing pad, (4) soft substrate to provide a nest cup, and (5) overhead cover to provide shelter and reduce detection by predators (Hamer and Nelson 1995, Nelson 1997, and Burger 2002). Conceptually, uneven-aged silvicultural practices or extended harvest rotations may maintain sufficient forest structure to support nesting murrelets, depending on gap size and the interspersion of trees and patches in the cutting unit. However, due to their association with old-growth forests it is apparent that nesting habitat for this species is not easily created and is likely that in young stands, suitable nesting habitat will not develop for 150 or more years (Albert and Schoen 2006).

An interagency conservation assessment of marbled murrelets in Southeast Alaska conducted in 1996 concluded that a murrelet conservation strategy should consider a reserve-based approach, especially in those biogeographic provinces where substantial timber harvest has been concentrated and is projected to continue (DeGange 1996). The current Forest Plan satisfies many of the measures identified in the assessment, including a Forest-wide system of OGRs and uneven-aged management in many areas that allow timber harvest. Standards and guidelines pertaining to marbled murrelets include maintaining a 600-foot (200-meter) radius no cut buffer zone around identified murrelet nests. However, marbled murrelet nests are extremely difficult to find, so in the Pacific Northwest where old growth is relatively rare, some resarchers have suggested that a more effective conservation strategy would be to maintain a 5-mile (0.8-km) radius buffer around any stand that is occupied by marbled murrelets (Raphael 2006).

Spruce Grouse

Spruce grouse (*Falcipennis canadensis*) are resident across much of northern North America, occurring from Alaska to Labrador southward into New England and into the northern states of the western U.S. The Prince of Wales spruce grouse is a subspecies that is endemic to Prince of Wales and nearby islands in southern Southeast Alaska.

Spruce grouse are closely associated with taiga and northern montane coniferous forests, with a lush understory of mountain cranberry, blueberry, crowberry, and spiraea growing on a thick carpet of mosses, where they rely heavily on pine and spruce needles as their main food source. Spruce grouse select relatively young successional stands that are dense with a well developed middle story. Microhabitat selection varies between seasons, with habitat selection being driven by snow during winter (they move from open stands to dense stands possibly in relation to the availability of snow of sufficient depth for snow roosting) and by food availability during summer (density of breeding females increases with the abundance of the shrub and herb layer). During dispersal and migration, birds traverse stands of deciduous growth, though they generally avoid non-forested habitat.

Spruce grouse in Southeast Alaska appear to be living in isolated and scattered low-density populations, which fluctuate overtime apparently in response to the degree of maturation of post-disturbance re-growth and predation pressure (Boag and Schroeder 1992). These small and isolated populations are particularly vulnerable to overexploitation associated with advancing roads and settlements. In addition, travel barriers created by development may reduce the exchange between neighboring populations, making it difficult for isolated populations to recruit new breeders. Though they are closely associated with conifer forests, the highest densities of spruce grouse are supported by areas with a mosaic of older coniferous habitats interspersed with regenerating patches of dense trees. Changes in forest structure, (e.g., timber harvest or windthrow) associated with fragmentation may lead to population declines if open areas are too large or forested patches are spread too far apart to enable spruce grouse to move between them. In the GMUs that encompass the Tongass (GMUs 1, 2, 3, 4, and 5), the ADF&G permits taking of spruce grouse between August 1 and May 15, with a bag limit of five per day.

Flying Squirrel

The northern flying squirrel (*Glaucomys sabrinus*) inhabits the boreal forests of Alaska, Canada, and the far northern U.S. and occurs on the mainland and southern islands in Southeast Alaska. The Prince of Wales flying squirrel subspecies (*G. s. griseifrons*) is endemic to Southeast Alaska and has been documented on Dall, El Capitan, Heceta, Kosciusko, Orr, Suemez, Tuxecan, Prince of Wales, and Barrier islands (Demboski et al. 1998, Smith 2005). The subspecies *G. s. zaphaeus* is more widespread in Southeast Alaska and occurs on the mainland.

The flying squirrel is a keystone species in the Pacific Northwest associated with late-seral habitat and is a diet specialist (mycophagous). Their density often increases with forest complexity. However, recent research has suggested that flying squirrels in Southeast Alaska differ ecologically from those in the Pacific Northwest, in that they are more closely associated with important, individual habitat attributes (large standing live and dead trees) that may be present in both old and complex young forests, and have been shown to use peatland-scrub-mixed conifer forests, rather than just old-growth forest (Smith and Nichols 2003, Smith et al. 2004b, Smith et al. 2005a). Surveys on Prince of Wales and Mitkof Islands indicated that the primary habitat of this species is high-volume POG, with some of the highest flying squirrel densities recorded in North America; however, breeding females were found in peatland and mixed-conifer stands, although demographic analyses showed that these were sink habitats (Smith and Nichols 2003). Additionally, a study on Prince of Wales Island found the density of large-diameter trees (greater than 74 cm dbh), abundance of *Vaccinium* shrubs, and density of large-diameter (50 to 74 cm dbh) snags was positively correlated with habitat use (Smith et al. 2004b). Although this study only looked at unmanaged landscapes, the authors suspected that had younger, less complex forest been included in their comparison, more attributes typical of old forest would have emerged as correlates of population density. Flying squirrels use large tree and snags for denning and nesting and require an adequate spacing of trees to travel through the forest. Thus, although flying squirrels may not be good indicators of "old" forest condition, they may be good indicators of landscape permeability in managed landscapes because successful dispersal of the species depends on the functional connectivity of the landscape (Smith et al. 2005a). The Prince of Wales subspecies was identified by the 1997 Forest Plan risk assessment panel as being at risk of extirpation in managed landscapes; however, the recent research described above indicates that this risk is likely less than presumed because abundant noncommercial forests appear to contribute to breeding populations (Smith 2005).

Flying squirrels are an important prey for various predators including great horned owls, Queen Charlotte goshawks, and marten, although few, if any, predators in Southeast Alaska specialize on flying squirrels (AKNHP 2006, Smith and Nichols 2003). Consequently, direct impacts to flying squirrels associated with habitat change may result in indirect impacts to predator populations. Timber harvest can adversely affect flying squirrel populations by creating restricted, isolated populations if clearcut size is too large or if some scattered tall conifers in large cuts are not retained as cover and for travel across the open spaces.

Migratory Birds

Executive Order 13186 (Responsibilities of Federal Agencies to Protect Migratory Birds) provides for the conservation of migratory birds and their habitats and requires the evaluation of the effects of federal actions on migratory birds, with an emphasis on species of concern. Federal agencies are required to support the intent of the migratory bird conventions by integrating bird conservation principles, measures, and practices into agency activities and by avoiding or minimizing, to the extent practicable, adverse impacts on migratory birds when conducting agency actions.

Neotropical migratory birds are far ranging species that require a diversity of habitat for foraging, breeding, and wintering. Therefore, patterns of population declines are generally detected at larger observational scales than those traditionally used to manage lands and by assessing habitat at a larger geographic scale, effects to overall biodiversity can be better incorporated into the planning process (Finch and Stangel 1992).

Over 100 species of birds migrate from the lower 48 states, Central and South America, to nesting, breeding, and rearing grounds in Alaska. Most of the birds fly to the interior or northern Alaska and only pass through southeast Alaska on their way to the breeding grounds. There are 114 "Important Bird Areas" identified by the Audubon Society, and a Partner for BirdLife International is working to identify a network of sites that provide critical habitat for birds. Of those areas identified, 49 sites have been recognized to date as important habitat for migratory birds in Alaska. Though there are no recognized Important Bird Areas within Southeast Alaska, a statewide Important Bird Area program is well underway (Stenhouse 2007). There are 40 protected bird species that may occur on the Tongass National

Forest; however, 20 bird species are identified as species of concern in Southeast Alaska (Boreal Partners in Flight 1999) and listed in Table 3.10-3.

Of the protected bird species, 35 are associated with old-growth and mature forest habitats, and thus are sensitive to timber management activities. Based on nesting behavior, these species fall into four categories including ground-nesting birds (blue and spruce grouse), cavity- and bark-nesting birds (12 species including woodpeckers, the brown creeper, swallows, forest owls, and wrens), tree- and shrub-nesting birds (20 species including flycatchers, warblers, forest raptors, crossbills, thrushes, kinglets, and corvids), and specialized nesters (dippers). Spruce grouse are discussed above in detail. Of the cavity- and bark-nesting birds, only the red-breasted sapsucker and northern saw-whet owl are migratory, the rest being year-round residents in Southeast Alaska. Cavity nesters require suitable nest cavities and adequate foraging habitats such as snags and dead wood material on live trees (e.g., broken tree tops) that are not recruited into harvested stands for more than 100 years (Sallabanks et al. 2001). For example, in a study of the effect of buffer width on breeding bird communities in the Tongass (Kissling 2003), 83 percent of brown creeper observations occurred in undisturbed control plots. Thus, the conversion of old-growth stands to clearcuts and younger successional stages reduces the amount of habitat available to these species. In addition, fragmentation increases forest edge area which can improve predator access and affect ecological dynamics of the forest through microclimatic effects (DellaSala et al. 1996).

Of the forest- and shrub-nesting species in Southeast Alaska, most are migratory. Large proportions of the global population of several species breed in Southeast Alaska (e.g., 21 precent of varied thrushes and 20 percent of Pacific-slope flycatchers). Though there is a general lack of information regarding habitat requirements for most of these species, many occur more commonly in high-volume, lower elevation old-growth forests compared with second-growth stands (DellaSala et al. 1996, Russel 1999, Kissling 2003, Zwickel and Bendell 2005). The Pacific-slope flycatcher, varied thrush, golden-crowned kinglet, and Townsend's warbler have the strongest association with old-growth and mature forest and require interior forest conditions (Stotts et al. 1999 as cited in Cotter 2007c). For Townsend's warblers, large trees have been found to be important as nest sites in Southcentral Alaska, with predation rates higher among nests in small trees than in large trees (Matsuoka et al. 1997a, 1997b). Kissling (2003) measured breeding densities of Townsend's warblers to be more than two times higher in forested beach buffers than in adjacent clearcuts. Like cavity- and bark-nesting species, open cup-nesting birds are also sensitive to fragmentation and tend to avoid nesting near forest edges where they are particularly vulnerable to predation (DellaSala et al. 1996). It is important to note that while studies of bird community response to timber harvest alternatives to clearcutting in Southeast Alaska do indicated that creation of forest edge may increase nest predation rates, the actual response depends on a broad array of factors and is highly variable.

A specialized-breeder, the American dipper is a dependent stream-dweller and a year-round resident of Southeastern Alaska (Gabrielson and Lincoln 1959 as cited in Cotter 2007a). Within Southeast Alaska, American dippers appear to migrate seasonally along an altitudinal gradient as they do elsewhere in their range (Johnson 2003 as cited in Cotter 2007a, Morrissey 2004). American dippers benefit from adequate riparian buffers and thus may serve as an indicator of watershed health throughout the forest (Cotter 2007a). Estuaries and the intertidal zone are also important seasonal habitats for this species (M. Willson, ecologist, Juneau, AK, personal communication 2004 as cited in Cotter 2007a). As with the other nesting guilds, American dippers are known to be sensitive to human activities that negatively affect the riparian zone (Kingery 1996).

Bird community composition and abundance has been shown to be correlated with forest buffer width, with widths in excess of 984 feet (300 meters) appearing optimal for many species (*Forest Birds* presented at the Tongass Conservation Strategy Review 2006). For example, Kissling (2003) found that densities of Pacific-slope flycatchers and Townsend's warblers were similar in buffers greater than 300 meters wide and in control sites, but lower in buffers less than 300 meters wide. Likewise, red-breasted sapsucker densities were positively associated with buffer width at the stand and landscape scales with densities greatest in buffers in excess of 300 meters. The largest effects were detected at the landscape scale, suggesting that a fragmentation threshold may exist for some species (Kissling 2003). Thus, as landsapes become more fragmented, forest buffers become increasingly important for migratory birds. Recent and ongoing studies that have evalatuated the effects of silviculture on bird communities include Deal et al. (2002), DellaSala et al. (1996), De Santo et al. (2003), De Santo and Willson (2001), Hennon et al. (2002), Holimon et al. (1998), Kissling (2003), Kissling and Lewis (ongoing), Matsuoka et al. (ongoing), Sieving and Willson (1998), and Sperry (2006).

Table 3.10-3
Migratory and Resident Birds Identified as Species of Concern in Southeast Alaska[1]

Common Name	Scientific Name	General Habitat	Preferred Habitat[2]	Abundance
Blue Grouse	*Dendragopus obscurus*	Habitat affinities vary by season and region. Coastal birds tend to remain in old-growth or recently logged forests all year. Inland birds prefer forest edges in summer, coniferous forests in winter (Kaufman 1996). Found in coniferous and mixed forests in Southeastern Alaska; also in dwarf conifer forests at treeline.	2, 3	Rare
Western Screech-Owl	*Otis kennicottii*	open coniferous and deciduous forests and along rivers, creeks, ponds and bogs. Also forest edges and in suburban areas in parks, orchards and gardens. Often nest near water (Campbell et al. 1990). In southern part of range in mesquite groves and saguaros (Kaufman 1996). Probably non-migratory in Alaska due to sufficient habitat to meet year-round requirements (P. Schempf, pers. commun.). In Yakutat, appears to favor riparian spruce (B. Andres, pers. commun.).	2	Uncommon
Black Swift	*Cypseloides niger (borealis)*	appear to be restricted to river valleys with steep unvegetated cliffs. Although nesting has not been confirmed in Southeastern Alaska, summer sightings in adequate habitat suggest Black Swifts are a probable breeder.	5	Rare
Vaux's Swift	*Chaetura vaux*i	Nests in coniferous and mixed forests, especially old growth. Often observed foraging over lakes, rivers, open country and clearcuts. Many records from Southeastern Alaska are along rivers and estuaries.	2	Uncommon
Rufous Hummingbird	*Selasphorus rufus*	Found in a variety of habitats throughout breeding range including old growth, second growth, thickets, and shrubby hillsides	2	Common
Red-Breasted Sapsucker	*Sphyrapicus ruber*	Often associated with mature stands, especially hemlock and/or spruce in Pacific Northwest and Southeastern Alaska, but may not be an obligate old-growth species.	2	Abundant
Olive-sided Flycatcher	*Contopus cooperi*	In Central Alaska, most often found in open conifer forest. Usually associated with openings (muskegs, meadows, burns, and logged areas) and water (streams, beaver ponds, bogs, and lakes). Apparently requires an uneven canopy or openings for aerial hawking, and wet areas productive of insect prey.	3	Uncommon
Western Wood-Pewee	*Contopus sordidulus*	In Southeastern Alaska, occurs along large mainland rivers, much less common on islands.	3	Uncommon
Hammond's Flycatcher	*Empidonax hammondii*	In southeastern Alaska, found in riparian deciduous forests.	2, 3	Uncommon
Pacific-slope Flycatcher	*Empidonax difficilis*	Prefers old-growth coniferous forests, especially near streams.	2, 3	Common
Steller's Jay	*Cyanocitta stelleri*	In Alaska, found predominately in coniferous forests	2	Abundant
Northwestern Crow	*Corvus caurinus*	Coastal beaches, rocky shores, estuaries, coastal ponds and inshore islands.	2, 6, 7, 8	Abundant

Table 3.10-3 (continued)
Migratory and Resident Birds Identified as Species of Concern in Southeast Alaska[1]

Common Name	Scientific Name	General Habitat	Preferred Habitat[2]	Abundance
Chestnut-backed Chickadee	*Poecile rufescens*	In Southeastern Alaska, common in mature hemlock/spruce forests and also in pole and sawtimber stages of successional forests	2	Abundant
American Dipper	*Cinclus mexicanus*	Dippers are a riparian-obligate species and are totally dependent on the productivity of streams and rivers.	4, 5	Fairly Common
Varied Thrush	*Ixoreus naevius*	Found mostly in thick, wet, coniferous forests of the coast.	1, 2, 3	Abundant
Townsend's Warbler	*Dendroica townsendi*	Largely restricted to mature forests with tall coniferous trees throughout its breeding range. Most abundant in large undisturbed tracts of contiguous forest, but will also use forests in late successional stages.	2, 3	Common
Blackpoll Warbler	*Dendroica striata*	Habitat preference variable, but usually found in tall shrubs (riparian woodland) or in coniferous or deciduous forest or woodland	2	Rare
MacGillivray's Warbler	*Oporornis tolmiei*	In southeastern Alaska, it is found in shrubs along hemlock/spruce edges, deciduous woodlands with shrubs, clearcuts, and riparian shrubs.	1	Uncommon
Golden-crowned Sparrow	*Regulus satrapa*	Prefers low to tall alder and willow scrub on hillsides and near tundra. Commonly found in proximity to lakes, streams, and bogs. In winter prefers uninterrupted brushland, streamside thickets, and chaparral.	1	Fairly Common
Golden-crowned kinglet	*Zonotrichia atricapilla*	Found in coniferous forests (spruce, fir, and hemlock) all times of year; also in mixed forests in southcoastal and central Alaska. In winter and migration, can be found in other trees and shrubs.	1, 3	Common

1/ Source: Boreal Partners in Flight Landbird Conservation Plan for Alaska Biogeographic Regions (1999)
2/ 1=shrub thicket; 2=hemlock/Sitka spruce/cedar forest; 3=mixed deciduous/spruce woodland; 4=fluvial waters; 5=cliffs, bluffs, and screes; 6=moraines, alluvia, and barrier islands; 7=beaches and tidal flats; 8=rocky shores and reefs.

Endemism

The Federal ESA defines endemic as "a species native and confined to a certain region; having comparatively restricted distribution." Forest Plan standards and guidelines for endemic mammals direct the Forest to "maintain habitat to support viable populations and improve knowledge of habitat relationships of rare or endemic terrestrial mammals that may represent unique populations with restricted ranges." Likewise, the NFMA directs that management prescriptions "shall preserve and enhance the diversity of plant and animal communities, including endemic(s)."

Due to its historic isolation, ecological complexity, and narrow distribution between the Pacific Ocean and coastal mountain ranges the North Pacific Coast is considered a hot spot for endemism (Demboski et al. 1999, Cook and MacDonald 2001, Cook et al. 2006). Southeast Alaska has been found to be a region with an especially high degree of endemism in its small mammal fauna, principally because of the combination of its archipelago geography and its highly dynamic glacial history (Demboski et al. 1998). Roughly 23 percent of the 107 mammalian taxa in Southeast Alaska (species and subspecies) are endemic to the region (MacDonald and Cook 1996 as cited in Cook et al. 2006, Cook et al. 2001). Recent molecular genetic analysis has enabled a more accurate look at the level of genetic divergence among island and mainland populations than previously possible; this analysis has refuted the classification of some taxa previously believed to be endemic and identified other taxa as endemic (see Dawson et al. [2007] for a current list of species and associated ranges). Two of these, the Prince of Wales flying squirrel and the Alexander Archipelago wolf, are incipient species, or subspecies that are beginning to diverge due to lack of interaction with other varieties of the same species (Bidlack and Cook 2001, *Other Mammals Including Endemic* presented at the Tongass Conservation Strategy Review Workshop 2006).

Current understanding of endemism in Southeast Alaska is based on the sampling of only a minority of the islands (just over 100 of the more than 2,000 named islands). The documentation of new distributions, new species, and distinct populations from this effort, much of which occurred between 1991 and 1999, suggests a high level of endemism on the Tongass (Cook et al. 2006). Thus, there continue to be gaps in knowledge about the natural history and ecology of wildlife subspecies indigenous to Southeast Alaska and conclusive geographic ranges of many endemics cannot yet be produced (Hanley et al. 2005, Dawson et al. 2007). Although mammals have been the primary focus of current research on endemics there are potentially other endemic animals (e.g., nonvolant taxa) that exist on the Tongass.(e.g, endemic spruce grouse on Prince of Wales Island and Zarembo Island). These include organisms such as plants, birds, amphibians, or invertebrates that may foreseeably have levels of endemism (Dawson et al. 2007).

Within the Alexander Archipelago, the Prince of Wales Island complex appears to be an endemic hotspot based on evidence that it was an area of refugia during the last glacial event (Cook et al. 2001). This has implications for management because there is notable overlap between this area, past timber harvest, and the potential for future timber harvest (Cook et al. 2006).

The island archipelago setting of the Tongass and naturally fragmented landscapes of Southeast Alaska, create challenges for management as natural interaction between subpopulations and individuals is often problematic, especially for species that cannot move between islands. The insular distribution patterns of many terrestrial mammal species among individual islands illustrates these dispersal limitations. For example, in study of population structure and genetic diversity in eight northern flying squirrel populations in the Alexander Archipelago (six island and two mainland populations), Bidlack and Cook (2001, 2002) found that island populations were less genetically diverse and that, on a genetic level, populations appeared to be isolated by distance, indicating that there is little long-distance geneflow across the archipelago. The authors found that six populations from the Prince of Wales complex are genetically very similar, suggesting current or recent geneflow among these islands, yet no apparent gene flow between the Prince of Wales complex and other populations in Southeast Alaska. Similar recent research on the demography, systematics, phylogeography, and post-glacial expansion of Southeast Alaska endemics has focused on the red-backed vole (Runck 2001, Cook et al. 2004, Smith and Nichols 2004, Runck and Cook 2005, Smith et al. 2005b), long-tailed vole (Conroy and Cook 2000), Keen's mouse (Lucid and Cook 2004, Smith et al. 2005b), dusky shrew (Demboski and Cook 2001), long-tailed shrew (Demboski and Cook 2003), ermine (Fleming and Cook 2002), marten (Stone and Cook 2002, Stone et al. 2002), wolverine (not endemic, but isolated populations with limited dispersal capability occur in Southeast Alaska; Tomasik and Cook 2005), and black bear (Stone and Cook 2000, Peacock et al. 2007). Major factors identified by these studies include reduced genetic diversity, limited dispersal capabilities, and the existence of highly divergent or relatively restricted western, or Pacific coastal, lineages of some species. This last factor was due to the existence of eastern and western forest refugia in North America during past glacial advances, all resulting in populations that are especially vulnerable to environmental stochastisity and anthropogenic disturbances.

Island archipelagos themselves are more sensitive to the effects of introduced exotics, emerging pathogens and disease (e.g., canine distemper), and natural events, such as climate change, than other managed landscapes, due to their insularity. Therefore, there is a higher probability of extinction on islands due to the restricted ranges of species, patterns of extinction are dynamic (i.e., in higher latitude archipelagos geographic ranges of mammals and recolonization abilitites fluctuate with glacial advances and retreats), and the effects of management activities are magnified. In fact, more than 81 percent of mammalian extincions in the last 500 years have been insular, endemic mammals (Ceballos and Brown 1995 as cited in Dawson et al. 2007). Noteably, while the distribution of mammalian species in Southeast Alaska is a function of the size of the island on which they occur and distance to the mainland, the distirubtion of endemic mammals is not (Conroy et al. 1999, Dawson et al. 2007). Thus, designing conservation measures based on island size or location will not effectively maintain the endemic diversity found in this region. Because of the uniqueness of this type of geographic setting and the vulnerability of species within it, some researchers have proposed structuring conservation efforts and land management planning along the North Pacific Coast around the issue of endemism (Cook and MacDonald 2001, Cook et al. 2001).

Invasive Species

Species are considered invasive if they are not native to an ecosystem, and are likely to cause harm to human health, the economy, or the environment (Executive Order 13112). Due to its remote landscape and climate, Alaska has relatively few invasive species compared to the rest of the United States. However, factors such as altered disturbance patterns, climate change, and the expansion of the transportation network in Alaska are expected to increase the prevalence of invasives. Global climate change also creates conditions suitable for new invasives by altering geographic range limits and by making habitats no longer suitable for native species.

Invasive species can affect native species by preying on them, competing with them, hybridizing with them, disrupting or destroying their habitat, or introducing pathogens or parasites that sicken or kill them. At least eight terrestrial species have been introduced into coastal Alaska habitats: Norway rat (*Rattus norvegicus*), European black slug (*Arion atter*), garden slug (*Arion* spp.), leopard slug (*Limax maximus*), elk (*Cervus elaphus*), house mouse (*Mus musculus*), starling (*Sturnus vulgaris*), and rock dove (*Columba livia*). Raccoons and snowshoe hares have also been introduced; however, due to their small population size and limited distribution, these species are not currently considered a threat to coastal Alaska ecosystems (Schrader and Hennon 2005). At this time, only rats are considered to be causing substantial ecological harm in coastal ecosystems and thus invasive, though there is concern about the expanding elk population (Schrader and Hennon 2005). With the exception of elk, which were introduced intentionally as part of a collaborative effort between ADF&G and the USDA Forest Service and are a desired non-native in some areas, all other species were unintentionally introduced.

Norway rats likely became established along the Alaska coast following shipwrecks of early European explorers and now occur in areas of human habitation and along coastal islands where food supplies are abundant (Schrader and Hennon 2005). The primary concern with this species is the adverse effects it may have on ground-nesting birds, as evidenced by rat populations on the Aleutian and Queen Charlotte Islands that prey on bird nests and have substantially impacted breeding bird colonies.

Elk were introduced to Alaska to develop additional hunting opportunities. As recently as 1987, ADF&G introduced elk on Etolin Island. Elk have spread to other islands and areas in the Southeast. A population occurs on Zarembo Island, and there have been reports of elk on other nearby islands including Onslow, Wrangel, Mitkof, Kupreanoff, Kashevaroff, Prince of Wales, Brush, Shrubby, and Farm islands. They have also been spotted on the mainland as far north as Cape Fanshaw, and one of the original transplanted and radio-collared elk was located at the mouth of the Stikine River (J. Brainard, USDA Forest Service biologist, Petersburg District, personal communication). Elk are a desired non-native species on Etolin and Zarembo islands, but there are still many unknowns about their presence and potential ecological effects elsewhere. The ADF&G Division of Wildlife Conservation has prepared a draft elk management plan for Southeast Alaska to manage and better understand the elk population and its potential effect on native plants and animals (ADFG 1999). The main concern is competition with native Sitka black-tailed deer due to the high degree of dietary overlap of the two species (ADFG 1999). This is primarily an issue on deer winter range, where deer are most limited by resource availability. Elk may reduce the available winter forage for deer through browsing, physically displace deer, alter predator-prey dynamics, and directly compete for food. The degree of dietary overlap between the species is the highest reported in the literature, indicating a high potential for direct competition (Kirchhoff and Larsen 1998). Pellet-count surveys on Etolin Island between 1991 and 1998 documented a doubling of the elk population while deer population declined by 56 percent (ADFG 1999). An associated issue is that a decline in deer numbers could lead to fewer deer hunting opportunities. One recommendation for managing the elk population outside Etolin and Zarembo islands is to increase harvest pressure.

There are also two invasive aquatic amphibian species that are present in coastal Alaska. The red-legged frog (*Rana aurora*), which is native to the Pacific Northwest, has established populations in several drainages on Chichagof Island and the Juneau area and recent surveys suggest that its range is expanding (MacDonald 2003). Effects of this species are currently unknown but potentially include the displacement of the endemic boreal toad (*Bufo borealis*) and wood frogs (*Rana sylvatica*) (MacDonald 2003). The Pacific chorus frog (*Pseudacris regilla*) has an established breeding population on Revillagigedo Island in a single pond complex (MacDonald 2003). Currently, this population is thought to be having little effect on native amphibian species, because in recent years boreal toads and rough-skinned newts (*Taricha granulose*) have successfully reproduced in the same pond complex (Schrader and Hennon 2005).

Consumptive Uses of Wildlife on the Tongass

A number of the wildlife species on the Tongass are important for subsistence, general hunting, or trapping. Sitka black-tailed deer, mountain goat, brown bear, black bear, moose, wolf, marten, river otter, and waterfowl (collectively) are all species with hunting and/or trapping seasons managed by the ADF&G. These species are also important for a variety of native and traditional uses that vary across the geographic area and cultural framework of Alaska. This factor must be considered in management actions because of the need to be in compliance with Title VIII of ANILCA requiring that the needs of rural residents be given priority when managing wildlife and fisheries resources in Alaska. This priority adds considerable importance to the job of monitoring management effects. The Federal Subsistence Board has management responsibility for subsistence taking of fish and wildlife on federal lands in Alaska and the State of Alaska has management responbility for subsistence and general taking of fish and wildlife on all lands in Alaska. The primary source of information on annual hunting and trapping is the ADF&G. Except for a summary for Sitka black-tailed deer, consumptive use information is not repeated here (see the *Subsistence* section for more information on subsistence uses of wildlife). The Sitka black-tailed deer is by far the most important, and most "harvested," terrestrial wildlife species for subsistence purposes, and for general hunting.

Based on ADF&G annual harvest summary reports, an average of 10,670 deer per year were harvested in Southeast Alaska from 1996 to 2004. This is approximately 2,400 deer per year lower than the average annual harvest over the previous 15 years (ADF&G 1996). Annual harvest fluctuated from year to year between 1996 and 2004 ranging from 8,574 deer harvested in 2002 to 12,289 in 1998 (ADF&G, various years). Deer harvest has not been evenly distributed throughout Southeast Alaska. Of total deer harvested during this period, approximately 70 percent were harvested from Admiralty, Baranof, and Chichagof islands, and adjacent small islands (GMU 4), where the deer hunting season is longer and bag limits are larger than other parts of Southeast Alaska. Another 23 percent came from Prince of Wales and adjacent Islands (GMU 2). Eight percent of the harvest came from both the group of islands that comprise GMU 3 (Kuiu, Kupreanof, Mitkof, Zarembo, Etolin, and Wrangell islands) and the mainland (GMU 1). Less than 1 percent came from Yakutat (GMU 5). This trend is similar to that reported over the previous 16 years (see 1997 Forest Plan Revision Final EIS for trends in deer harvest between 1981 and 1996), though the proportion of harvest in GMU 3 has increased since that period, likely because much of that area was closed to deer hunting in the 1980s. Total annual harvest has remained stable over the same period in GMUs 1, 2, and 4; ADF&G began conducting surveys in GMU 5 in 1997 and harvest in this area remains low, but appears to be gradually increasing.

The number of deer hunters decreased between 1996 and 2003 from 8,270 to 7,028, for an average of 7,632 deer hunters per year (ADF&G various years). This is approximately 8 percent lower than the long-term average reported for the 15 years prior to 1996 (ADF&G 1996). The average success rate for deer hunting from 1996 to 2003 was 1.4 deer per hunter, which is slightly lower than the long-term average (1.6 deer per hunter). Likewise, the average annual success rate during this period (60 percent success) was lower than the long-term average (63 percent success).

In 1987-1988, ADF&G conducted a survey within Southeast Alaska, asking deer hunters how many deer they desired to harvest (annually). The average from this survey was 4.2 deer, but respondents indicated they would be satisfied with an average of 2.7 deer. It has been estimated that a deer population at carrying capacity could support an annual harvest by hunters of up to about 10 percent of winter carrying capacity, with the population remaining stable and hunter satisfaction (success/effort) remaining fairly high (Flynn and Suring 1993). When harvest approaches 20 percent of carrying capacity, hunter satisfaction may diminish, and the harvest may be unsustainable over time, particularly in areas with high predator populations. If deer populations are above long-term carrying capacity, such as after several mild winters, hunter success may remain temporarily high.

Environmental Consequences

Introduction

This section builds on the effects analysis conducted for the 1997 Tongass Forest Plan Revision Final EIS (USDA Forest Service 1997a). It is based on the known (or estimated) requirements of selected wildlife species with varying needs related to old-growth forest; there is no assurance that all, or even most, other old-growth associated species have similar needs or are adequately represented. Our knowledge of the specific viability requirements of most Tongass wildlife species is limited. We do know that the old-growth forest ecosystem is the dominant forest system in Southeast Alaska and provides habitat for most of these species, and is the primary habitat type potentially affected by the programmatic changes discussed here. Therefore, an analysis that focuses primarily on the old-growth ecosystem will best address or capture the requirements of all the old-growth associated species.

NFMA requires that the Forest Service provide for the diversity of plants and animals, based upon the suitability and capability of each National Forest, as a part of meeting overall multiple-use objectives (16 USC 1604(g)(3)(B)). The NFMA implementing regulations define diversity as "the distribution and abundance of different plant and animal communities and species within the area covered by a [forest plan]" (36 CFR 219.3). In addition to providing diversity direction (at 219.26), the NFMA regulations include the following provisions for managing habitat to maintain viable populations of wildlife species:

> Fish and wildlife habitat shall be managed to maintain viable populations of existing native and desired non-native vertebrate species in the planning area. For planning purposes, a viable population shall be regarded as one which has the estimated numbers and distribution of reproductive individuals to insure its continued existence is well distributed in the planning area. In order to insure that viable populations will be maintained, habitat must be provided to support, at least, a minimum number of reproductive individuals and that habitat must be well distributed so that those individuals can interact with others in the planning area. (36 CFR 219.3)

The Multiple Use-Sustained Yield Act of 1960 states that "the national forests are established and shall be administered for outdoor recreation, range, timber, watershed, and wildlife and fish purposes" (16 U.S.C. 528). The Act further directs the Forest to maintain renewable surface resources for multiple use and sustained yield. Likewise, under NFMA, forest plans are required to incorporate multiple use and sustained yield principles. Accordingly, another important purpose of the Tongass Forest Plan is to manage wildlife resources in such a way that, in addition to ensuring that viable wildlife populations are sustained, consumptive (hunting) and non-consumptive (wildlife viewing) opportunities are maintained.

In order to accomplish these requirements, an Old-Growth Conservation Strategy (Conservation Strategy) was developed within the framework of the 1997 Forest Plan to maintain viable and well distributed populations of old-growth associated species on the Tongass. The Conservation Strategy is the product of the integration of several science-based efforts that were informed by the latest concepts in conservation biology and landscape ecology. These efforts include the Interagency Viable Population Committee's (VPOP) proposed strategy for conserving old-growth associated vertebrates on the Tongass, which ranked species according to the concern for their viability and well distributed status and developed conservation strategies for the highest concern species (Suring et al. 1993). This proposal, its peer review (Keister and Eckhardt 1994), and ensuing response (Suring et al. 1994) formed the basis for two components of the Conservation Strategy: a coarse filter and a fine filter approach to conserving biodiversity on the Tongass.

The coarse filter component to the Conservation Strategy is the old-growth strategy which divides the Forest into reserves consisting of protected lands which include non-development LUDs, and a system of small, medium, and large OGRs located strategically across the landscape. The reserves, based on the system of large and medium Habitat Conservation Areas (HCAs) originally mapped by VPOP, were designed to protect the "biological heart" of the forest and maintain a functionally interconnected old-growth ecosystem. In general, the size, spacing, and number of reserves were based on the home range and dispersal capabilities of old-growth associated species of concern. In addition, many other non-development LUDs (e.g., wilderness) were identified as functioning as large and medium OGRs. To address the need for larger habitat reserves and minimize fragmentation, the Forest Plan also contains at least one "very large" reserve within each of the 21 biogeographic provinces across the Tongass. However, there was insufficient information to finalize the location of all small OGRs prior to the 1997 Forest Plan.

VPOP recommended placing a small HCA in each 10,000-acre watershed with the objective of "providing temporary functional habitat for animals dispersing between large and medium HCAs and to ensure that species of concern have a relatively high likelihood of occurring in each $10,000^{+}$-acre watershed." The task of refining the location of small reserves has been conducted since then on a project-by-project basis per VPOP recommendations. During the current Forest Plan amendment process, an interagency team developed biological recommendations for the majority of the small OGRs on the Tongass. These recommendations were reviewed and refined at the District and Forest Supervisor levels to account for multiple uses and the resulting refined small OGR proposal is incorporated into Alternatives 1, 2, 3, and 6 in this assessment (see Appendix D)..

Between 1997 and 2008, lands within the non-development LUDs have increased by 2,000 acres through reallocation, even though the total lands within the Tongass have decreased (primarily due to land adjustments). The Old-Growth Habitat LUD area has increased based on 24 project analyses conducted during this period, and the percentage of Tongass POG in reserves has increased from 70 to 71 percent (see Appendix D). Matrix lands, which include timber management lands, constitute areas where timber harvest can occur. Primarily since the 1950s, approximately 450,000 acres of POG has been converted to young-growth stands under the Tongass timber management program (Table 3.9-2 in the *Biodiversity* section provides a breakdown of cover types on the Tongass by biogeographic province and Table 3.9-8 provides a breakdown of POG harvest by decade).

The second component of the Conservation Strategy is a fine-filter approach, which includes species and habitat specific standards and guidelines that provide for connectivity between reserves and address old-growth structural needs within the matrix lands. Some of the primary management prescriptions, designed to ensure protection of a significant proportion of high-quality habitat within the matrix, are the 1,000-foot beach and estuary fringe and the riparian buffers. Other standards and guidelines preclude or significantly limit timber harvest in areas of high hazard soils, steep slopes (greater than 72 percent), high vulnerability karst terrain, visually sensitive travel routes and use areas, and timber stands technically not feasible to harvest. In addition to providing additional old-growth protection, many of these prescriptions provide important connectivity functions within and between matrix lands and the larger OGR system lands outlined in the Conservation Strategy. There are also specific standards and guidelines designed to protect key wildlife habitat structure (e.g., reserve trees and cavity nesting habitat).

Matrix lands are receiving growing attention for the importance they potentially play in maintaining well distributed and viable wildlife populations. Some species, particularly those that are wide ranging, require large blocks of continuous habitat to meet their life requirements. They also require surrounding habitat within the matrix for movement. Wolves and nesting pairs of goshawks, for example, require land bases that are larger than most OGRs on the Tongass and use resources within matrix lands to meet their life requisites and facilitate movement. Matrix lands are also important for supporting prey populations of many old-growth associated species.

Previously, little emphasis was given to the young second-growth component of the matrix in terms of its ability to contribute structure, function, or value to wildlife. However, there appears to be a growing perception that, with active management, young stands can contribute at least some of the values commonly associated with old growth (Barbour et al. 2005). Key features of old-growth forest include large, old decadent trees, multiple canopy layers, standing snags, down woody debris, and a diverse and abundant herb layer. These features can be maintained or created by retaining structures and organisms at the time of regeneration harvest of old-growth forest and through active management of young, even-aged stands. Some potential approaches to even-aged management involve thinning of older, “commercial”-aged young-growth stands (Deal 2001, Deal and Tappeiner 2002, Deal et al. 2002), including red alder (*Alnus rubra*) in the reforestation of harvested areas to expedite the production of large-diameter conifers (Deal 1997, Deal et al. 2004, Hanley et al. 2006), and the initial use of alternatives to clearcutting (McClellan et al. 2000). It should be emphasized that additional research on the implementation of these techniques is needed.

For example, both pre-commercial and commercial thinning of young-growth stands have beneficial impacts to black-tailed deer by opening up the forest and promoting the growth of understory vegetation. Likewise, active young-growth management has the potential to benefit both marten and goshawk through an increase in small mammal populations (red squirrels and red-backed voles, major prey items of these species, benefit from more open forests with abundant understory vegetation) and by speeding the succession of older young-growth stands toward old-growth condition (Hanley 1996, 2005). Although the time frame in which young-growth stands become suitable habitat for many species is beyond the lifespan of the Forest Plan, it is something to be considered as part of a long-term vision for management of the Tongass. It must be noted, however, that there research on the effectiveness of young-growth management is on going and peer-reviewed results are not yet available. The evidence in support of the potential benefits of young-growth management for multiple values is derived from a series of demonstration projects that have tested various second-growth management methods (e.g., Zaborske et al. 2002; Deal et al. 2004; McClellan 2004, 2005; Wipfli et al. 2003), retrospective assessments (Hanley and Barnard 1998), and other observations. Thus, there remains much uncertainty about the true benefits of second-growth management to wildlife. Although active management will likely improve habitat conditions in young conifer stands, significant questions remain regarding the types of treatments, treatment timing, and cost/benefit tradeoffs.

Effects Analysis

Framework for Analysis

Alternatives 1, 2, 3, 5, and 6 do not propose to change the framework of the existing Forest Plan Old-Growth Conservation Strategy. That is, these alternatives maintain a strategy divided into coarse filter (system of protected lands) and fine filter (species- and habitat-specific standards and guidelines) management regimes, which appears to be an appropriate framework for maintaining well distributed and viable wildlife populations on the Tongass. Alternative 4 modifies the coarse filter component by requiring OGRs in only four of the most heavily modified biogeographic provinces (North Central Prince of Wales, Kupreanof/Mitkof Islands, Dall Island and Vicinity, and East Chichagof Island) in addition to maintaining two individual reserves including the Wright Lake (mainland southeast of Wrangell), and Myers Chuck (Cleveland Peninsula northwest of Ketchikan) reserves and creating one near Eva Lake (northeast Baranoff Island) in an area currently designated as semi-remote recreation. In addition, all VCUs outside of these biogeographic provinces would be required to retain 33 percent of their old growth with no requirement to consider spacing, location, size, shape, or composition in the design of the retained acres, as are provided by Appendix K of the current Forest Plan (Old-Growth Habitat Reserve Criteria). Alternative 7 maintains substantial area in non-development LUDs, but eliminates the system of OGRs and would not have a specific retention requirement..

Alternative 5 would maintain the current standards and guidelines described in the 1997 Forest Plan. Consistent under Alternatives 1, 2, 3, and 6 are proposed changes that modify the existing standards and guidelines or create new standards and guidelines that are similar to those under Alternative 5. These alternatives would replace the Goshawk Foraging and Marten Habitat standards and guidelines with a Forest-wide Legacy Structure standard and guideline, revise the Goshawk Nest standard and guideline, and modify a number of other standards and guidelines (see Appendix D and the accompanying Forest Plan volume). Alternatives 1, 2, 3, and 6 also propose boundary modifications to the existing system of small OGRs (see the interagency effort described above in the Introduction). Rationale and background for these changes are provided in Appendix D.

Alternatives 4 and 7 eliminate the Goshawk Foraging and Marten Habitat standards and guidelines, but do not apply the Legacy Structure standard and guideline. Alternative 4 maintains the existing Goshawk Nest standard and guideline, whereas Alternative 7 eliminates it and relies on the general Raptor Nest standard and guideline to provide protection.

The following wildlife analysis is subdivided into three major sections. The first section focuses on the Conservation Strategy where changes to LUD designations, impacts to the OGR system and landscape connectivity, and matrix land management are discussed. The old-growth ecosystem is discussed in the *Biodiversity* section, but is briefly addressed here relative to the Conservation Strategy's ability to maintain viable populations of old-growth associated species. The second section focuses on species-specific direct and indirect impacts related to habitat capability for ESA Candidate species, MIS, Forest Service Sensitive species, and other selected terrestrial wildlife species; impacts to ESA-listed species (which only include marine mammals and fish) are discussed in an updated Biological Assessment (Appendix F). Where appropriate, changes to standards and guidelines are discussed. Consideration of endemic and invasive species under the Forest Plan is also briefly addressed. The third section of this analysis evaluates cumulative effects of the proposed Forest Plan amendment on wildlife. Potential effects of the proposed action are discussed inlight of, the risks associated with uncertainties related to existing knowleged of species distributions and habitat relationshiops, the efficacy of the of protective measures under the conservation strategy, the future direction of forest management on the Tongass, and overall unpredictable enrivonmental factors such as climate change.

Old-Growth Forest Conservation Strategy

When considering the viability of old-growth associated species, the possible effects of alternatives, and the likelihood of maintaining viable well distributed populations, the assumption is made that if a functional interconnected old-growth ecosystem is maintained, then its component parts (composition and structure) and processes (function) are maintained. The likelihood of these outcomes is discussed in detail in the *Biodiversity* section. The framework of the old-growth conservation strategy relative to wildlife viability is now further described as two basic components: 1) the reserve system in terms of its ability to effectively maintain the integrity of the old-growth forest ecosystem through non-development LUDs such as Wilderness Areas, Research Natural Areas, Remote and Semi-Remote Recreation, and Old-Growth Habitat, among others, and 2) matrix lands where development, such as timber harvest and road building, is permitted that will alter the old-growth forest ecosystem on a portion of the lands. These development LUDs are restricted by a suitability determination process (see *Timber* section), which precludes the harvest of forest stands that would result in impacts to long-term site productivity or cause irreparable damage (e.g., mass wasting), and other Forest-wide standards and guidelines.

The amount of matrix lands (development LUDs) versus reserve system lands (non-development LUDs) is one measure of the ability of the alternatives to protect the integrity of the old-growth forest ecosystem. There are approximately 3.6 million acres of matrix lands under Alternative 5 (No Action), which would slightly decrease under the Alternative 6. Alternatives 3, 2, and 1 would provide increasingly greater protection by reallocating existing matrix lands to various non-development LUD designations, resulting in approximately 3.0 million, 2.0 million, and 938,000 acres of matrix, respectively. In contrast, Alternatives 4 and 7 would create an additional 1.1 million and 1.5 million acres of matrix lands relative to Alternative 5, respectively (see Table 3.10-4).

Table 3.10-4
Summary of Acres in Matrix and Reserve Lands by Alternative

Alternative	Matrix[1]		Reserve[2]	
	Acres	% of Landbase	Acres	% of Landbase
Alternative 1	840,359	5.0%	15,933,443	95.0%
Alternative 2	1,929,485	11.5%	14,844,321	88.5%
Alternative 3	2,803,945	16.7%	13,969,858	83.3%
Alternative 4	4,727,686	28.2%	12,046,116	71.8%
Alternative 5	3,605,974	21.5%	13,167,834	78.5%
Alternative 6	3,457,420	20.6%	13,316,385	79.4%
Alternative 7	5,049,695	30.1%	11,724,107	69.9%

[1] Includes Modified Landscape, Timber Production, Scenic Viewshed, and Experimental Forest LUDs
[2] Includes all other LUDs where timber harvest is prohibited or restricted

Table 3.9-12 in the *Biodiversity* section shows the acreage and percentage of POG, high-volume POG, and large-tree POG that would be contained within reserves and matrix lands, and the acres that would be protected from harvest in the matrix, under each alternative. Table 3.10-5 (below) provides a summary of the percentage of POG in each category, under each alternative. There are approximately 4.95 million acres of POG remaining on the Tongass. Alternative 5 (No Action) provides a combination of land allocations that protects at least 91 percent of this acreage over the long-term, and is believed to reduce the overall risk and increase the likelihood of maintaining viable and well distributed populations of old-growth associated species. Alternatives 1, 2, 3, and 6 would also protect at least 91 percent of the existing POG. However, Alternatives 4 and 7 would protect 87 and 84 percent, respectively. Within reserves (non-development LUDs), which represent long-term habitat patches or blocks of POG, the greatest percentage of existing POG would be maintained by Alternative 1 (93 percent), followed by Alternatives 2 and 3 (84 and 78 percent, respectively), Alternatives 5 and 6 (71 and 72 percent, respectively), and Alternative 7 (57 percent). Tables 3.9-14 and 3.9-18 in the *Biodiversity* section present additional detail on the percentages of POG protected in reserves and throughout the landscape by biogeographic province and ecological subsection, respectively. Harvest under all of the alternatives would be concentrated in four biogeographic provinces (North Central Prince of Wales Island, Etolin Island and Vicinity, Kupreanof/Mitkof Islands, and Revillagigedo Island/Cleveland Peninsula), where substantial amounts of timber harvest have already occurred. That is, a majority of harvest under all alternatives occurs in or near the roaded base (areas where roads are already constructed) which is concentrated in the four aformetioned biogeographic provinces. As the alternatives increase in harvest intensity, the area harvested progressivly extends beyond that roaded base.

Table 3.10-5.
Percentage of Existing Productive Old-Growth Acreage in Reserves, Protected/Unscheduled in the Matrix, and Suitable for Timber Harvest in 2008

Alternative	POG Area in Reserves	POG Area in Matrix – Protected or Unscheduled: Protected in Beach Fringe, Riparian, & Other	POG Area in Matrix – Protected or Unscheduled: Suitable, But Not Scheduled for Harvest	Total Protected POG	Total POG Suitable for Harvest[1]
1	93%	4%	1%	98%	2%
2	84%	10%	2%	96%	4%
3	78%	14%	2%	94%	6%
4	60%	25%	1%	87%	13%
5	71%	18%	1%	91%	9%
6	72%	17%	2%	91%	9%
7	57%	26%	1%	84%	16%

[1] Represents the maximum POG that could be harvested assuming POG harvest takes place at the maximum rate.

The 1997 Forest Plan Revision Final EIS expert panel assessment concluded that due to the Forest-wide system of OGRs and standards and guidelines that provide additional protection to old-growth habitat, Alternative 11 (the basis for Alternative 5 in this EIS) would provide an amount and distribution of habitat adequate to maintain viable populations of vertebrate species across the Tongass and to maintain the diversity of plant and animal communities. Wildlife dependent on old-growth and/or unroaded habitats would have a moderately high likelihood of being maintained as viable and well distributed across the Tongass. Alternative 5 in this EIS was based on the 1997 Alternative 11, but incorporates the amendments that have occurred since 1997. These amendments have slightly increased the proporation of non-development LUDs so Alternative 5 would be slightly more protective than the 1997 Alternative 11.

The same conservation measures are generally maintained under Alternatives 1, 2, 3, and 6. The largest change is the replacement of the goshawk and marten standards and guidelines with the legacy standards and guidelines. As a result of this change, legacy would still be provided in the highest risk areas, but there would be slightly less POG protected within the matrix overall. However, the fact that these alternatives would allocate larger acreages to non-development LUDs produces more POG in reserves and a greater overall percentage of protected POG. In addition, these alternatives would protect a higher overall percentage of the larger tree POG types (both high-volume POG and big-tree POG), and would generally protect more POG and more larger tree POG in the most heavily harvested biogeographic provinces compared with Alternative 5 (see the *Biodiversity* section). Therefore, their likelihood of maintaining viable, well distributed populations of old-growth associated species across the Tongass would be higher. Because of the reduction or elimination of the OGR system under Alternatives 4 and 7, respectively, and the increase in area of development LUDs, these alternatives would have a reduced ikelihood of maintaining viable, well distributed populations relative to Alternative 5.

As discussed above, matrix lands, including both old growth and some older young growth (e.g., stands of 25 to 150 years of age), are important in facilitating movement of wildlife across the landscape and providing life requisites to many species. However, young-growth stands vary in their value to wildlife but can potentially contribute more, in terms of structure and function, through active stand management. There are approximately 687,000 acres of young-growth stands (including both harvested and natural young growth) on the Tongass. Under all the action alternatives, several Forest-wide standards and guidelines have been modified to specifically address young-growth management. The Timber Management standards and guidelines direct the Forest to "implement commercial thinning treatments in young conifer stands to obtain chargeable timber, improve wildlife habitat…" Likewise, wording has been added to the Transportation Road Management standards and guidelines to "consider future needs for commercial thinning." The term "young-growth management" has been incorporated into existing standards and guidelines for Wildlife Habitat Improvement. Finally, the Forest is also planning for thinning in non-development LUDs to improve wildlife habitat. Management of young growth will increase over time and will produce positive benefits to wildlife by shortening the stem-exclusion phase of stand development when tree crowns are crowded and forage availability is at its lowest.

Landscape Connectivity

Fragmentation associated with habitat loss results in smaller sizes of habitat patches available to a species, increased distances among habitat patches, increasing amounts of matrix conditions in which habitat patches are embedded, and altered spatial distribution of habitat types (Haufler 2007). These factors are strongly tied to the structural and functional connectivity of the landscape, and thus the ability of the landscape to support well distributed and viable wildlife populations. When a landscape becomes fragmented (i.e., when habitat patches become small and farther apart), a continuously distributed population may become a series of small, isolated subpopulations that rely on the ability of dispersing individuals to facilitate genetic interchange between populations and to recolonize area following local extirpation. Consequently, smaller, less mobile species that have limited dispersal capabilities and species that occupy limited ranges (e.g., endemics) are likely to experience the largest population level effects of fragmentation. Consequently, matrix lands play a vital role in providing functional connectivity across fragmented landscapes (Szacki 1999).

Timber harvest under all alternatives would increase fragmentation and reduce landscape connectivity. Alternative 7 proposes the greatest amount of timber harvest and therefore would result in the greatest increase in habitat fragmentation, followed by Alternatives 4, 5, 6, 3, 2, and 1, in decreasing order (Table 3.10-5 and Table 3.9-11 in the *Biodiversity* section). Most of this harvest would occur in the North Central Prince of Wales Island, Etolin Island, Kupreanof/Mitkof Island, and Revillagigedo Island/Cleveland Peninsula biogeographic provinces, which have already been heavily impacted by timber harvest.

The OGR system, as noted above, is an important component of the Conservation Strategy aimed at maintaining the amount and distribution of old growth on the Tongass. A reserve system would be maintained under Alternatives 1, 2, 3, 5, and 6. By limiting the OGR system to four highly developed biogeographic provinces and instating a retention requirement elsewhere, Alternative 4 would not be as effective in maintaining landscape connectivity over the long-term if retained acres are widely distributed, in small parcels, are linear in shape, and are not located to specifically protect important habitat features (e.g., suspected goshawk nesting habitat or deer winter range). This is particularly relevant in the Etolin and Revillagigedo Island/Cleveland Peninsula biogeographic provinces where a substantial amount of timber harvest is proposed but where no reserve system would be in place. Alternative 7 would have effects similar to Alternative 4, but to a greater extent because it eliminates old-growth habitat reserves all together.

The following discussion addresses the areas identified as being critical links connecting portions of the landscape in areas where a high amount of timber harvest has occurred, or is likely occur in the future:

Pinch-point No.1: This pinch-point is located in the middle of the East Chichagof biogeographic province, one of the more heavily developed provinces. This area is completely protected by a large OGR under Alternative 5, which provides connectivity between northeast Chichagof Island and the rest of the island. Alternatives 1, 2, 3, and 6 maintain this protection and add to it to varying degrees through the reallocation of the adjacent Timber Production lands to Remote and Semi-remote Recreation where minimal timber harvest is allowed. These alternatives ensure that habitat protection is in place to facilitate wildlife movement through the pinch-point as well as provide connectivity to a large area of LUD II and the West Chichagof-Yakobi wilderness area to the west.

This pinch-point would receive little protection beyond what is provided by the beach fringe in Alternatives 4 and 7, which designate the area as development LUDs. Alternative 4 proposes to shift the large OGR to the southeast, and Alternative 7 removes it completely, eliminating any actual old-growth connectivity across the pinch-point, except that which is provided by the beach buffer, which is only 500 feet wide in Alternative 7. Not only would Alternatives 4 and 7 isolate old-growth habitat in the vicinity of the pinch-point, but they could potentially isolate a portion of Chichagof Island if timber harvest limits wildlife movements through this corridor.

Pinch-point No. 2: The area connecting Lisianski Inlet with the North Arm of Peril Strait on Chichagof Island is pinch-point No. 2. This area is fully protected as a Legislated LUD II area in all alternatives.

Pinch-point No. 3: This area includes the Port Camden-Bay of Pillars connection and the portage between Port Camden and 3-Mile Arm and serves as a major linkage connecting north Kuiu with east Kuiu Island and Rocky Pass on its eastern edge; and North and South Kuiu Island. This area is protected by Old-Growth Habitat, Semi-Remote Recreation, and Remote Recreation LUDs under Alternatives 1, 2, 3, 5, and 6. In contrast, under Alternatives 4 and 7, all of the Old-Growth Habitat LUDs in northern and eastern Kuiu would be reallocated to development LUDs; some non-development LUD would remain around the Bay of Pillars. Thus, Alternatives 4 and 7 could negatively affect wildlife movements between major portions of the island.

Pinch-point No. 4: Pinch-point No. 4 is the narrow area between Lindenburg Peninsula and the remainder of Kupreanof Island and it is largely protected by the Petersburg Creek-Duncan Salt Chuck Wilderness. The remaining small area not included in the Wilderness between Portage Bay and Duncan Salt Chuck is primarily forested peatland. Under all alternatives the beach fringe buffer provides some additional connectivity but to a lesser extent under Alternative 7 because it reduces the buffer from 1,000 to 500 feet.

Pinch-point No. 5: This area connects the extreme north end of Prince of Wales Island to the remainder of the island, where there has been substantial past and on-going forest management activities. Under Alternatives 1, 2, 3, 4, 5, and 6 a cross-island connection is nearly protected by a small OGR around Neck Lake, and fully protected farther south by a very large reserve (including Remote Recreation LUD) around Sarkar Lakes. Because much of the pinch-point is highly developed, additional habitat alterations could create barriers to movement. Furthermore, the critical connecting habitat of this area is primarily inland (both shorelines are private land), and thus existing standards and guidelines for beach fringe and estuary buffers under all alternatives are not likely to maintain much additional connectivity. All action alternatives add a small Special Interest Area south of Neck Lake, which would be withdrawn from timber management. No OGRs exist under Alternative 7, thus reducing the likelihood of functional cross-island connectivity.

Pinch-point No. 6: This area is now all private land, dividing the north-central and south portions of Prince of Wales Island with a non-NFS strip of land one to two miles wide. Continued timber harvesting is anticipated on these private lands, with the potential to create migration and dispersal barriers. All action alternatives provide some additional protection to this pinch-point, relative to Alternative 5 (No Action), by designating a Special Interest Area adjacent to the non-NFS land. However, Alternative 7 eliminates all the Old-Growth Habitat LUDs in the vicinity of the pinch-point, thus reducing the functional connectivity of the old-growth ecosystem in the surrounding area.

Species Assessments

As noted above, the NFMA directs the Forest to manage wildlife habitat to maintain viable and well distributed populations to ensure continued existence in the planning area. Quantitative criteria for viability are not specified by the NFMA or associated regulations. For this analysis, the evaluation of viability includes considerations of its unique island archipelago environment as well as current scientific thinking on population viability and conservation biology, as found in the general literature and that compiled during the recent Tongass Conservation Strategy meeting (2006).

This section briefly discusses potential effects to all Candidate, Forest Service Sensitive listed species, MIS, and selected other species of concern. There are several species that have been identified as species of special management concern, and for which a more in-depth fine filter analysis is necessary. As discussed under the Affected Environment portion of this section, these include two species evaluated for possible listing under the Endangered Species Act (Alexander Archipelago wolf and goshawk), the most important wildlife species for consumptive use (Sitka black-tailed deer, also important as the principal prey for the wolf), and two other species important as old-growth habitat indicator species and long-term viability concerns (brown bear and marten).

The 1997 Forest Plan Revision Final EIS wildlife analysis relied in part upon expert panel evaluations of alternatives in terms of the estimated relative risks to a species or habitat of concern. Seven "panel assessments" were conducted: one for wolf, marten, goshawk, brown bear, marbled murrelet, "other terrestrial mammals" including endemics, and one for the old-growth ecosystem. Each of these old-growth associated species was selected ostensible because collectively their ecologies incorporated the breadth of forest habitat features and other attributes of environmental variation represented across the Forest, and because they were thought to be representative of a subset of species that are sensitive to disturbance and potentially at risk of either becoming locally extirpated or jeaopardizing cultural or subsistence uses. This approach has been effectively used in the Pacific Northwest and was chosen for the Tongass because a substantial amount of uncertainty existed in the understanding of various wildlife habitat and community relations and there was generally inadequate information on which to base predictive models (i.e., population viability anaysis).

The panel assessments resulted in the generation of a set of estimates of the likelihood of various outcomes related to the persistence of each species under each plan alternative, which were then examined to determine the influence of the alternatives on viability across the Tongass (Shaw 1999).The panel assessments evaluated alternatives in terms of their ability to maintain the continued existence of well distributed, viable wildlife populations across the Tongass. A 100-year time period, or planning horizon, was used for the viability analysis, which was assumed to be the minimum period over which viability could be evaluated based on current scientific literature. This time period is the average rotation age under even-aged management and thus the time period over which old-growth characteristics would be affected (see the *Wildlife* section of the 1997 Forest Plan Revision Final EIS for further justification for this planning horizon and additional description of the panel assessments). It should be noted that within its first decade, the current Forest Plan has harvested much less timber than originally estimated in the 1997 Final EIS.

Candidate Species

Kittlitz's Murrelet

Due to the Kittlitz's murrelet's association with glacial habitat, this species occupies areas outside of where timber harvest and associated activities have occurred or are likely to occur. Major threats to this species are global climate change, which is correlated with a loss of suitable habitat (glacial melt) and reduction in prey availability due to warming sea temperatures. Human activity in the marine environment, particularly vessel traffic and fishing operations, are additional threats to this species. There is no indication that any Forest Service management activity is affecting the Kittlitz's murrelet (USDA Forest Service 2004h). Consequently, implementing any of the alternatives will not directly or indirectly affect the Kittlitz's murrelet.

Forest Service Sensitive Species

Queen Charlotte (Northern) Goshawk

Iverson et al. (1996) concluded that landscapes that maintained a forest age structure consistent with a 300-year ecological rotation would provide a high likelihood of sustaining goshawks. This composition would generally consist of one-third each of 0- to 100-year old stands, 100- to 200-year old stands, and 200-year old or older stands, categories with increasing value to goshawks. Additionally, harvest under a 300-year ecological rotation permits a maximum of 3.3 percent of the 1954 old growth to be harvested per decade in order to maintain a forest age structure favorable to goshawks. The 1997 Forest Plan Revision Final EIS compared alternatives in terms of their ability to support viable populations of goshawks over the long-term, by evaluating the number of VCUs where harvest levels met these criteria. This was based on the notion that the average size of a VCU approximates the size of a goshawk territory and that they are old-growth obligates, though recent research has shown that goshawks range wider and use a greater variety of habitats than once thought (Boyce et al. 2006, Reynolds et al. 2006). As a measure of the ability of each alternative to support well distributed viable goshawk populations, this discussion takes a more conservative approach by focusing on impacts to high value goshawk nesting and foraging habitat (SD5N, SD5S, and SD67 stands located below 800 feet in elevation) but on a forest-wide basis, and discusses trends in areas with the greatest risk of not supporting goshawks due to the high levels of past disturbance.

Protection of high value goshawk habitat would be greatest under Alternative 1 (24,000 acres proposed for harvest), followed by Alternatives 2 (48,000 acres), 3 (68,000 acres), 6 (97,000 acres), 5 (102,000 acres), 4 (145,000 acres), and 7 (191,000 acres). Table 3.10-6 summarizes the percentage of high-volume POG and large-tree POG that is suitable for harvest under each alternative. These percentages represent the maximum potentially harvested over 100+ years of Plan implementation. The extent to which harvest impacts the ability of an area to support goshawks is dependent on the amount of suitable habitat remaining in the resulting landscape. That is, areas that originally had a substantial amount high-volume POG before timber harvest began and where much of that amount remains (e.g., Admiralty Island and Central Coastal Range biogeographic provinces) have a higher likelihood of supporting healthy goshawk populations even with additional harvest. Table 3.9-15 in the *Biodiversity* section displays the original acres of high-volume POG and the minimum percentage remaining after 100+ years of Plan implementation by biogeographic province.

Table 3.10-6
Maximum Percentage of Existing High-Volume (SD5N, SD5S, and SD67) and Large-Tree (SD67) Productive Old-Growth Proposed for Harvest by Elevation Category and Alternative after 100+ years

Elevation Category	Alternative						
	1	2	3	4	5	6	7
High-Volume POG							
< 800 feet	2.0%	4.0%	5.6%	11.9%	8.3%	7.9%	15.6%
> 800 feet	2.0%	6.1%	8.5%	16.8%	12.0%	11.6%	19.3%
Total	**2.0%**	**4.8%**	**6.7%**	**13.8%**	**9.8%**	**9.3%**	**17.1%**
Large-Tree POG							
< 800 feet	2.9%	5.1%	7.0%	12.8%	9.5%	9.0%	17.0%
> 800 feet	3.0%	8.5%	10.8%	19.8%	14.6%	13.9%	22.6%
Total	**2.9%**	**6.1%**	**8.1%**	**14.8%**	**11.0%**	**10.4%**	**18.6%**

Biogeographic provinces with greatest potential reduction in high value goshawk habitat include North Central Prince of Wales, Kupreanof/Mitkof, Etolin and Vicinity, and Revilla Island/Cleveland Peninsula. Highest harvest in these provinces would occur under Alternative 7. However, it is important to note that under Alternatives 1, 2, 3, 4, 5, and 6 this loss is limited to old growth within the matrix and that the large and “very large” OGRs established under the Forest Plan were intended to compensate for timber management activities in the most developed areas. In the Prince of Wales Island area, for example, these include the Sarkar/Honker Divide/Karta Wilderness reserve that totals over 200,000 acres, the 200,000-acre reserve on South Prince of Wales, and a 56,000-acre reserve at Mt. Calder/Mt. Holbrook on Kosciusko Island.

Alternative 5 (No Action) also incorporates a set of standards and guidelines that were intended to address aspects of goshawk habitat such as connectivity and stand structure in highly developed areas. These include the goshawk foraging habitat standards and guidelines, which require that timber harvest units must meet certain minimum criteria designed to maintain forest stand structure characteristics thought to be beneficial to goshawks in VCUs on Prince of Wales Island where more than 33 percent of the POG has been converted to young-growth, and the goshawk nest standard and guideline. Additional protection of habitat elements important to goshawks is provided by marten habitat standards and guidelines (see description under marten). Both sets of guidelines only apply to provinces where harvest has been relatively extensive. The retention of additional forest structure in harvest units was thought to result in improved foraging habitat for goshawks and facilitate dispersal among OGRs. However, recent science supports retaining clumps of legacy trees rather than a uniform distribution of legacy trees (see Appendix D and *Northern Goshawks on the Tongass National Forest*, presented at the Tongass Conservation Strategy Review Workshop 2006). That is, even spacing of reserve trees may, in effect, create a thinned stand that over time grows into a forest with understory shrubs and trees filling in spaces under the forest canopy, inhibiting goshawk maneuverability for foraging within the stand.

Based on the 1997 panel assessment ratings (Iverson 1997), Alternative 5 (rated as its precursor, Alternative 11 in the 1997 Forest Plan EIS) was rated as having a high likelihood of sustaining viable, well-distributed goshawk populations during the 100-year planning horizon and unlikely to result in a loss of viability or a declining trend that would require additional protection (see Appendix D). In addition, the panel concluded that there was no possibility of extirpation from the Tongass and virtually no possibility the goshawk would exist only within isolated refugia populations under Alternative 5. It is important to recognize that the panel assessments were conducted prior to the development of the Goshawk and Marten standards and guidelines (discussed above). In addition, recent research suggests that goshawks may be more adaptable to managed forest conditions than once thought, though they rely on prey that are closely associated with old growth. Thus, the 1997 panel ratings, which considered the goshawk an old-growth obligate, may provide a conservative assessment of impacts to goshawks.

Alternatives 1, 2, 3, and 6 maintain the reserve system (slightly to substantially expanded over Alternative 5) and the various buffer standards and guidelines, but propose a new Forest-wide Legacy Forest Structure standard and guideline, in place of the existing Goshawk Foraging Habitat and Marten Habitat standards and guidelines. The Legacy Forest Structure standard and guideline is designed to protect forest legacy components in areas that are already highly developed, as well as areas that will experience increased harvest levels over the life of the Forest Plan. Thus, the Legacy Forest Structure standard and guideline is not limited to certain biogeographic provinces and, therefore, covers more provinces than the Goshawk standard and guideline (see Appendix D for a detailed analysis and comparison of the Legacy and Goshawk standards and guidelines). Because Alternative 6 would protect slightly more POG and a higher percentage of larger tree POG types within reserves, than Alternative 5 (Tables 3.10-5 and 3.10-6) and incorporates the Legacy standard and guideline, it is expected that long-term effects on goshawks would be similar to or slightly less than under Alternative 5. Because Alternatives 1, 2, and 3 would all result in lower harvests than Alternatives 5 and 6, it is expected that they would result in a very high likelihood of sustaining viable, well-distributed populations over the long term (based on their old-growth harvest levels, including larger POG types – see Table 3.10-6).

The reduction of the OGR system, in combination with the absence of species-specific or Forest-wide forest legacy retention, under Alternatives 4 and 7, respectively, would increase risk to goshawk populations. However, Alternative 4 maintains a relatively extensive reserve system in four of the most heavily developed biogeographic provinces, including the above mentioned “very large” reserves in the Prince of Wales Island complex. The distribution of these reserves is such that nearly all matrix habitats outside of these reserves and other protected areas are within the dispersal distance of goshawks, thus increasing the likelihood of re-colonization of landscapes that may be at risk of not supporting goshawks (USDA Forest Service 1997a). However, by significantly reducing reserves elsewhere and not providing legacy tree requirements, Alternative 4 could reduce the dispersal and re-colonization capability of goshawks in areas where timber would be harvested in the future. Even so, Alternative 4 would still only result in a harvest level of less than 12 percent of the existing low elevation, high-volume POG (considered to be the highest value goshawk habitat) after 100 years (Table 3.10-6). Based on the 1997 expert panel assessments (Iverson 1996a), Alternative 4 (equivalent to Alternative 6 in the 1997 FEIS) would be rated as having a moderately high likelihood of maintaining viable, well-distributed goshawk populations; the assessments also noted no possibility of extirpation from the Tongass, but a low likelihood that the alternative would result in the goshawk existing only in isolated refugia (Appendix D).

The likelihood of effects on goshawk distribution would be greater under Alternative 7, which eliminates much of the coarse-filter component of the Conservation Strategy (the Old-Growth Habitat LUD), as well as the species-specific Goshawk Foraging and Marten Habitat standards and guidelines. Full implementation of Alternative 7, would result in harvesting approximately 16 percent of the existing low elevation, high-volume POG after 100 years (Table 3.10-6). Based on the 1997 expert panel assessments (Iverson 1997a) Alternative 7 (equivalent to Alternative 2 in the 1997 FEIS) would be rated as having a moderate likelihood of maintaining viable, well-distributed goshawk populations; the assessments also noted there would be a very low possibility of extirpation from the Tongass and a low likelihood that the alternative would result in the goshawk existing only in isolated refugia.

Osprey

Limiting factors for osprey populations are unknown, but availability of nest sites and foraging areas do not appear to be limiting on the Tongass and Forest-wide standards and guidelines were developed to provide for protection of nest sites as they are identified. In addition to protection around known nest sites, standards and guidelines also include a 1,000-foot beach and estuary buffer that provides suitable dominant or co-dominant trees along shorelines, essentially protecting all suitable or potentially suitable nesting, perching, and foraging habitat for ospreys. Although in other parts of their range ospreys do nest on freshwater lakes, where no such buffer applies, none have been documented in Southeast Alaska. Consequently, no impacts to osprey or osprey habitats are anticipated from Alternatives 1, 2, 3, 4, 5, and 6, which uphold the current Forest Plan standards and guidelines. Ospreys would be at increased risk of effects associated with timber management activities under Alternative 7, which proposes to reduce the beach fringe buffer to 500 feet; however, this distance is likely to protect most nesting habitat.

Peale's Peregrine Falcon

Forest-wide standards and guidelines were developed to provide for protection of Peale's peregrine falcon habitat. Any project level planning requires the evaluation of potential impacts to known falcon nests within 2 miles of a proposed project in an effort to plan project activities to avoid adverse impacts to the falcons and their habitats. These standards and guidelines would be maintained under all the action alternatives, therefore no effects are anticipated for peregrine falcons.

Trumpeter Swan

The largest concentration of nesting trumpeter swans on the Forest is at Yakutat, in the Yakutat Forelands Biogeographic Province (primarily Roadless Area 339). Approximately 96 percent of this province is already within legislated LUD II areas or other natural setting LUDs; none of the alternatives propose changes to these designations. The entire nesting habitat is classified as wetlands and/or riparian habitat. Forest-wide standards and guidelines for wetlands and riparian management apply to these areas, which were specifically developed for trumpeter swan habitats on the Forest.

None of the alternatives would increase the likelihood of any adverse effects on trumpeter swan populations, nesting habitat, or wintering habitat, or would result in a loss of species viability. Therefore, no effects are anticipated for trumpeter swans.

Management Indicator Species

Sitka Black-tailed Deer

This analysis of effects to black-tailed deer uses the deer winter HSI model described in the Affected Environment section to evaluate impacts to winter range habitat capability potentially resulting from each of the alternatives. The Forest Plan model uses four discrete variables (four levels of snow depth, three elevation zones, four aspects, and seven vegetation/successional stages) to predict a habitat suitability index. For this application, a cross-walk was developed to reclassify the new Forest-wide vegetation model (the SDM) into the model vegetation categories (See Appendix B for additional details about the deer model analysis). This results in an overall reduction in average HSI values because fewer stands would be classified as high and medium volume strata and more stands would be classified as low volume strata compared to the old volume strata mapping used in the 1997 Forest Plan Revision Final EIS. However, this makes no difference to the analysis because relative values were used to compare alternatives. For reference, high volume stands include SDM vegetation categories SD5N, SD5S, and SD67; medium volume stands include SD4N, SD4S, and SD5H; and low volume stands include SD4H (see the *Biodiversity* section for further discussion of the SDM categories).

The deer model is used here to compare the alternatives in a relative sense. However, it should be noted that, for several reasons, the model is believed to overestimate the effects of harvest. Please refer to the discussion of these factors under the Sitka Black-tailed Deer subsection of the Affected Environment.

For the purpose of this analysis, the following assumptions were made:

- HSI values were standardized to range from 0 to 1.0, by dividing all values by 1.3, because outputs from such models represent a range from 0 to 100 percent habitat suitability, with higher values indicating higher habitat capability.
- After full implementation of the Forest Plan (100+ years), all suitable acres are harvested; calculations take the model implementation reduction factor (MIRF) into account which is the reduction between planned and actual timber volume/acres due to the presence of karst, unstable soils, and other issues that preclude harvest during timber sale layout. These numbers are based on known differences between the acres of forest land mapped as suitable for timber management and the number actually harvested on the Tongass (see the *Timber* section and the project record for additional discussion).
- To estimate 1954 habitat capability, previously harvested stands were assumed to be medium (SD4N, SD4S, SD5H categories) and high (SD5N, SD5S, and SD67 categories) volume forest; stand with a date of origin prior to 1954 were not changed.
- To project future habitat capability, 25 percent of the current young-growth stands would be in the stand initiation phase (25 years old or younger) and 75 percent would be in the stem exclusion phase (26 to 150 years old) by 2105; previously harvested stands that are unsuitable for harvest would be in the stem exclusion phase.
- This analysis evaluated relative changes in habitat capability; actual habitat capability may be more or less than model predictions.
- Lands under non-federal ownership have an assumed habitat capability of zero (see discussion below).

After the initial years following logging, there is a rapid increase in deer forage production due to the large amount of light penetration created by open stand conditions. However, this nutrition is of lower quality than the same forage types found in old growth. After the initial 20 to 30 years, there is a 100- to150-year period in which the vigorously growing hemlock and spruce shade out the understory forage. Person et al. (2001) described this situation as “succession debt” because the full impacts to deer may not immediately be expressed but will be sustained for many decades after timber harvesting. Under even-aged and two-aged harvest systems, the amount of habitat capability reduction over the 100-year analysis period is substantial and is directly related to the amount of timber harvest. While the short-term (20- to 30-year) effect is also related to the amount of timber harvest, the effect of timber harvest will vary with the average seasonal snow accumulation (since higher accumulations reduce forage availability). Under uneven-aged systems (such as group selection), available forage within any given area would be maintained for a longer time, as would adjacent thermal cover. Assumptions related to future forest condition are intended to model future deer habitat capabilties after harvest. For this analysis, the effects of harvest are modeled over the long term and all harvest is assumed to consist of regeneration methods (e.g., clearcut harvest). Regeneration methods and rotation length depend on site-specific analysis done at the project level.

Effects on winter range habitat capability by WAA, as indicated by changes in HSI scores, are displayed in Table 3.10-7. This does not include any State, City, or private land. Many of these lands have been, or will be, developed for intensive forestry and are expected to have lower habitat capability over time. WAAs are land divisions used by the ADF&G for deer inventories and planning. Table 3.10-7 illustrates the cumulative effect of timber harvest on estimated deer habitat capability, from the beginning of large-scale timber harvest on NFS lands in 1954 to the present and to year 2105 and includes the 10-year (1996 to 2005) average harvest intensity, measured in hunter-days, by WAA.

In addition, the percentage of high value habitats available for timber harvest was also calculated by WAA to quantify impacts to high quality deer winter range (Table 3.10-8). To take into account impacts to deer across the Tongass inhabiting areas that vary naturally in their habitat quality, high quality habitat was defined as the quartile of the land base with the highest HSI scores within in each WAA. Lands not available for timber harvest include areas within LUDs that do not permit timber harvest and areas that are protected by Forest-wide standards and guidelines, such as Riparian or Beach and Estuary Fringe.

Forest-wide, the alternatives are estimated to retain from 77 to 86 percent of the original winter range habitat capability in 100+ years (Table 3.10-7). At the WAA level, Alternatives 4 and 7 show the greatest reductions in deer habitat capability because they propose the greatest amounts of harvest. Most of the largest reductions in habitat quality occur in WAAs that have already experienced a high amount of past timber harvest (e.g., Prince of Wales and Kuiu Islands); however, there are several WAAs (e.g., 2008, 2305, 2927, 3524) where currently over 95 percent of the 1954 deer habitat capability remains, that would receive substantial reductions under some of the alternatives.

On average, the highest percentage of high quality winter range habitat subject to timber harvest is proposed under Alternative 7 (16 percent per WAA), followed by Alternatives 4 (13 percent), 5 (9 percent), and 6 (8 percent), 3 (6 percent), 2 (4 percent), and 1 (1 percent; Table 3.10-8). Forest-wide, however, the alternatives would harvest 1 to 5 percent of the existing high quality winter range (Table 3.10-8). Table 3.10-8 also displays the range of HSI scores in each WAA. At the WAA level, there are some areas where 40 to 55 percent of the high value deer winter range could be harvested under Alternatives 4, 5, 6, and 7. This magnitude of effect would be primarily concentrated on Prince of Wales Island, the Cleveland Peninsula and nearly islands, Baranof Island, and Mitkof Island.

Over the long-term, reductions in habitat capability and harvest of high value deer winter range could reduce carrying capacity, or the numbers of deer in areas capable of supporting them given the available resources, such that deer populations would decrease in areas that could no longer support the current population. This would primarily be a concern during severe winters, when resources are already limited. Ultimately reductions in the deer population resulting from decreased habitat capability could reduce the number of deer available to wolves and hunters. At some low level, wolf predation could actually limit deer population recovery (the “predotor pit” hypothesis (Boutin 1992), though there is no threshold population level or threshold loss of winter range that has been defined for Southeast Alaska with which to predict these potential population responses.

However, it is also important to note that forest management on the Tongass has produced more forage than assumed by the model, through the management of second-growth stands. The purpose of young-growth management is to accelerate the stem exclusion phase of forest development, which occurs roughly 15 to 25 years following a major disturbance when the growing space is fully occupied and tree crowns are crowded. Deer forage availability is at its lowest during this time due to the lack of light penetrating the understory, which causes lower tree limbs and understory plants to die and less vigorous trees to be shaded out. Activities such as thinning, girdling, or pruning, which open the forest canopy, result in increased understory biomass thus increasing the amount of forage available to deer. Since 1970, the Tongass has treated approximately 168,000 acres of second-growth, mostly by precommercial thinning; roughly 16.000 acres were treated specifically for wildlife and riparian objectives (*Young-growth Management*, presented at the Tongass Conservation Strategy Review Workshop 2006). However, it is important to note that there are still many uncertainties related to appropriate young-growth treatment designs, specific beneficial effects of such treatments, and implications for deer. In addition, some studies have shown the opposite results. Farmer (2006) found that the risk of death to fawns was positively correlated with pre-commercial thinning. The Tongass, in collaboration with the Pacific Northwest Research Station, is conducting the Tongass-Wide Young Growth Study (TWYGS) to address many of these uncertainties. TWYGS is the most extensive and intensive study of young-growth ever conducted in Southeast Alaska and is designed to evaluate the potential benefits of treating pre-commercial stands to increase wildlife habitat and wood production. Initial results indicate that the potential for restoring diverse and abundant understory plant communities through the active management of young stands is promising (*Young-growth Management*, presented at the Tongass Conservation Strategy Review Workshop 2006).

Mountain Goat and Black Bear

These species occupy different niches but both are associated with old-growth forest and are susceptible to over-hunting if road access is increased or improved, though most roads are located a long distance (both vertically and horizontally) from goat habitat. The amount of road access, quantified in terms of the amount of road construction and reconstruction proposed under each alternative, is assumed to be inversely related to the amount of POG conserved after full implementation of the Forest Plan (100+ years) and to be representative of the potential for over-hunting. This provides a rough index for assessing risk to these species, since roads can be designed (or closed) at the project level to avoid key habitats. Risk of over-harvest due to human access along roads is mitigated to some extent by Transportation Forest-wide standards and guidelines that require travel access road objectives to be developed for all roads, and Mountain Goat and Black Bear Forest-wide standards and guidelines directed toward assessing and minimizing disturbance and access to meet management objectives. A maximum of 3,874 miles of road construction and 2,100 miles of road reconstruction would be implemented after 100+ years of Forest Plan implementation under Alternative 5 (No Action). Alternative 6 (3,744 miles), Alternative 3 (2,799 miles), Alternative 2 (2,079 miles), and Alternative 1(774 miles) provide decreasing risk to these species associated with new road construction; all of these alternatives maintain or decrease the currently estimated level of road reconstruction (ranging from 2,046 miles under Alternative 6 to 925 miles under Alternative 1). Only Alternatives 4 and 7 would increase the proposed amount of road construction (4,890 miles and 5,825 miles, respectively) and reconstruction (2,182 miles and 2,371 miles, respectively). Thus

Total		88	86	84	83	79	81	82	77		

[1] Includes only National Forest System lands
[2] Based on 1995 to 2005 ADF&G harvest summary reports
[3] This analysis assumes: 1) maximum timber harvest levels over the 100^{+}-year period, 2) timber harvest from 1954 to 1995 occurred in the high volume stratum (SD 5N, 5S, 67), 3) in 2105 25 percent of the second-growth would be in stand initiation (<25 years) and 75 percent would be in stem exclusion (26-100 years),
[4/] Estimates incorporate the model implementation reduction factor (MIRF), which is the reduction in the number of suitable acres actually harvested during plan implementation (see *Timber* section for further description).

1 Scores range from 0 to 1.0, with higher numbers indicating higher habitat quality.
2 High quality habitat was defined as the top 25 percent of acres within each WAA with the highest HSI scores. The analysis excluded all lands with HSI scores of 0 before identifying high quality habitat; WAA 202 contains only two polygons, both with HSI scores of 0, and therefore was not included in this table
3 This analysis assumes maximum timber harvest levels and takes the Model Implementation Reduction Factor (MIRF) into account (see the *Timber* section for additional discussion).

Alternatives 4 and 7, in increasing order, would have the greatest potential to lead to over-hunting of mountain goats and black bears because of increased access.

Both mountain goats and black bears are also susceptible to disturbance associated with helicopter overflights and landings. In a study of mountain goat responses to helicopter disturbance, Cote (1996) documented temporary displacement from the area of disturbance, the disintegration of social groups, and injury while fleeing. Cardiac responses (i.e., elevated heart rate) have been documented in bighorn sheep which occupy similar habitats. Distance between animals and helicopters appears to be the most important factor affecting mountain goat responses and disturbance can occur as far away as 2 kilometer from a helicopter flight (Cote 1996). Though no studies have been completed to date that examine the long-term consequences of this disturbance on mountain goats (Wilson and Shacklston 2001), it has been suggested that behavioural disruptions in response to disturbing stimuli result in demographic consequences (e.g., Côté 1996). For example, disturbance increases energy expenditure due to the flight response, and has the potential to affect foraging, socialization, and other life-history strategies which could ultimately affect mortality and natality. This would be most likely when mountain goats are already under seasonal nutritional or energetic stress such as when they are on winter range or kidding areas,.

Recent trends indicate that use of helicopters by the tourism industry to reach remote areas has increased since 1997 and is anticipated to continue increasing (see Recreation section for further discussion). However, Forest Plan standards and guidelines in place address helicopter use at the project scale, though there is still some uncertainly related to their adequacy due to the lack of long-term studies on disturbance effects.

River Otter

River otters prefer habitats immediately adjacent to coastal and fresh water aquatic environments, with most use occurring within 500 feet. Old-growth forests in these areas provide the highest value habitat, providing cover and burrow and den sites (Suring et al. 1988). The majority of otter habitat is secure under the existing Forest Plan because of beach, estuary, and riparian Forest-wide standards and guidelines; therefore, there is no increased risk associated with Alternatives 1, 2, 3, 4, 5, and 6, which maintain existing 1,000-foot Beach and Estuary Buffer standards and guidelines. Alternative 7 proposes to reduce the beach fringe buffer to 500 feet. Although most use by river otters occurs within this distance, the additional 500 feet are important for providing connectivity. Consequently, the reduced buffer under Alternative 7 may result in more road construction and timber harvest closer to areas inhabited by otters thereby providing less protection of otter habitat.

American Marten

The most important factors related to viability of the marten populations on the Tongass are the large amount of habitat in OGRs and non-development LUDs, followed by habitat characteristics of the matrix. Within the matrix, forest structure at the stand level (e.g., forest cover and components that contribute to structural diversity such as large trees, snags, and downed logs) and landscape connectivity are important factors. Marten are strongly associated with late-seral and old-growth forests below 1,500 feet in elevation. They are also wide ranging and require large tracts of contiguous habitat to move across the landscape, as well as habitats capable of supporting an adequate prey-base of small mammals.

The elevation preferences for marten presents the potential for a viability concern in that high quality habitats generally contain a greater, relative proportion of mature forest and thus have also historically received a disproportionately high level of harvest and associated road effects of harvest. That is, new roads may lead to increased human access and thus the potential for increased trapping pressure. Consequently, beach and riparian zones are particularly important for this species in terms of landscape connectivity and prey habitat diversity. As noted under the Affected Environment section, recent research has shown that prey availability and harvest play significant roles in the population dynamics of this species.

There are currently approximately 1.83 million acres of high volume (SD5N, SD5S, and SD67 categories) old growth below 1,500 feet in elevation on the Tongass. Under Alternative 5 (No Action), a maximum of 9.7 percent of these acres could be harvested over the next 100+ years. Alternatives 1, 2, 3, and 6 would each protect more acres of high-volume old growth below 1,500 feet elevation than Alternative 5, with potential harvest ranging from 2.0 percent of the acres under Alternative 1 to 9.3 percent of the acres under Alternative 6. Alternatives 4 and 7 would protect fewer acres of high-value marten habitat, with the potential harvest ranging from 13.8 percent to 17.2 percent, respectively.

Based on the 1997 expert panel assessments for marten (DeGayner 1997), it can be concluded that Alternative 5 (which is the equivalent of Alternative 11 in the 1997 Forest Plan Revision Final EIS) would have a moderate likelihood of sustaining viable, well-distributed marten populations because it incorporates three key features thought important for marten use: wider riparian management buffers; 1,000-foot beach and estuary buffers; and a system of small, medium, and large reserves (Appendix D). Subsequent to the panel assessment, Alternative 5 was strengthened by incorporating additional measures, including the requirement for special prescriptions for managing high-value marten habitat in timber harvest areas to retain important components of forest stand structure in higher risk biogeographic provinces where timber harvest has reduced the abundance of habitat components important to marten. The overall objective was to avoid the creation of additional significant gaps in marten habitat that could inhibit interaction between subpopulations by limiting harvest units to 2 acres in size and applying even-aged harvest at a 200-year rotation in highly fragmented VCUs and, in less fragmented

VCUs, retaining structures that will allow harvested units to regain value as marten habitat in a relative short amount of time by retaining coarse woody debris and green trees to act as a source of woody debris during the next rotation (Appendix N, 1997 Final EIS). These Marten Habitat standards and guidelines only apply to areas identified as high value habitat by the marten habitat capability model.

Alternatives 1, 2, 3, and 6 maintain key features and management prescriptions under Alternative 5, propose the less cumulative harvest of POG (acres after full implementation of the Forest Plan), and protect more POG and a higher percentage of larger tree POG types in reserves. These alternatives also replace the existing Marten Habitat and Goshawk Foraging standards and guidelines with a Forest-wide Legacy Structure standard and guideline. The Legacy Forest Structure standard and guideline continues to meet the objectives of maintaining sources of coarse woody debris important for marten and of reducing fragmentation to facilitate movements of marten between OGRs and is to be applied in the high risk VCUs Forest-wide, including the biogeographic provinces that have not had concentrated past timber harvest activity but where concentrated harvest could take place in the future. Additionally, it specifies a clumped distribution of reserve trees and therefore would implement a larger number of acres of even-aged management, whereas the existing standards and guidelines specify that reserve trees be uniformly distributed across a unit (see Section 2.5 of Appendix D for a detailed analysis and comparison). In addition, the potential road densities are lower under Alternatives 1, 2, 3, and 6, thereby reducing the chances of increasing trapping pressure on marten through increased human access. Therefore, Alternatives 1, 2, and 3 provide better protection of key marten habitat components and connectivity across the landscape than Alternatives 5 (No Action), and are more likely to continue to support well distributed, viable marten populations on the Tongass. Alternative 6, which harvests slightly less timber than Alternative 5, would also be expected to have a moderate likelihood of sustaining well-distributed viable populations of marten (Appendix D). Similar to Alternative 5, Alternative 6 was strengthened by incorporating additional measures that would increase the likelihood of maintaining habitat to sustain viable marten populations. Measures include increased protections of old growth in both the reserve system and within non-development LUDs, standards and guidelines regarding trapping mortality and road density and the Legacy Forest Structure standards and guidelines. Given the smaller suitable land bases and implementation of the Legacy Structure standards and guidelines under Alternatives 1, 2, and 3, these alternatives are expected to have a very high (Alternative 1) to high (Alternatives 2 and 3) likelihood of sustaining viable, well-distributed populations of marten over the long-term (Appendix D).

Alternatives 4 and 7 propose to harvest amounts of POG similar to Alternatives 6 and 2 of the 1997 Forest Plan Revision Final EIS, respectively (greater than under Alternative 5), reduce or eliminate the OGRs system, and eliminate the Goshawk Foraging and Marten Habitat standards and guidelines. In addition, there is no Forest-wide Legacy Forest Structure requirement. Alternative 7 would also reduce the beach fringe from 1,000 to 500 feet. Based on the 1997 expert panel assessments (Iverson 1996a, DeGayner 1997) both Alternatives 4 and 7 would be rated as having a moderate chance of maintaining habitat sufficient to support well-distributed viable marten populations across the Tongass (Iverson 1996a, DeGayner 1997). As a result,it is likely that under these alternatives more isolated populations could result. The extensive planned roading, potentially leading to increased trapping pressure, continued fragmentation of habitat, and the higher harvest rate for the important high-volume old-growth forest component were factors cited by panelists that contributed to these conclusions.

Brown Bear

The quality and quantity of riparian habitats play an essential role in sustaining brown bear populations, both in terms of the maintaining adequate vegetative cover to support anadromous fish production (i.e., regulate stream temperature) and providing visual obscurity of bears from humans and other bears. The existing Brown Bear standard and guideline requires a minimum no-harvest buffer of 500 feet around important brown bear foraging sites. Additionally, the reserve system serves as an important source of roadless refugia for bears, reducing the possibility of human-bear interactions. The 1997 Forest Plan panel members viewed factors that increased road construction and repeated human entry into a watershed as adverse to brown bears. Of particularly concern are activities that are dispersed or occur over an extended time period because once an area is roaded for one development activity, it often results in additional developments that increase human-bear interactions, and ultimately reduce the area's capability for supporting high bear populations. Wilderness and LUD II areas were determined to essentially ensure brown bear persistence somewhere in Southeast Alaska over the 100-year planning horizon.

Alternative 5 (No Action) emphasizes protection of known high value brown bear areas, protection of riparian habitats, control of human access, sanitation management, and the system of OGRs to maintain viable and well distributed brown bear populations on the Tongass. Based on the 1997 Final EIS expert panel assessments, Alternatives 5 and 6 (equivalent to Alternative 11 of the 1997 Final EIS) would be ranked as having a high likelihood of maintaining viable brown bear populations over the long-term due to the reserve system (related to road effects) and the riparian buffer requirements (Meade 1997). Alternatives 1, 2, and 3, which maintain the conservation measures in place under Alternative 5 related to brown bears but propose less timber harvest and road construction, would have a very high (Alternatives 1) or high (Alternatives 2 and 3) likelihood of maintaining well-distributed, viable brown bear populations over the long term (Appendix D).

As noted in the description of the Affected Environment in this section, brown bears are primarily found north of Frederick Sound. Alternative 4 maintains some protection of known high value brown bear areas by requiring OGRs in the Northeast Chichagoff Island biogeographic province within ADF&G GMU 4 (Admiralty, Baranof, Chichagof, and surrounding islands), which supports the highest concentration of brown bears in the world. It is important to note though that Northeast Chichagof Island continues to support this population despite already having experienced a high level of timber harvest with roads having been built in nearly every watershed, many of which are closely associated with major fish streams (ADF&G 2000). In addition, Alternative 4 would also locate an individual reserve, the Eva Lake reserve, which is currently designated as Semi-remote Recreation LUD, in an ADF&G brown bear special use zone on Baranoff Island. Alternative 7 would completely eliminate the OGR system. Based on the 1997 panel assessment (Meade 1997, Iverson 1996b) Alternatives 4 and 7(equivalent to Alternatives 6 and 2 of the 1997 Final EIS, respectively) would be ranked as having a moderately high relative likelihood of maintaining well-distributed, viable brown bear populations with some potential for the development of temporary gaps in distribution, due to the reduction in the reserve system (Appendix D). Although, risk would be greatest under Alternative 7 due to the more extensive timber harvest, associated road construction, and absence of an OGR system. OGRs serve as important roadless refugia for bears where human-bear interactions can be minimized, and that provide connectivity between upland areas and habitats used by bears for foraging (riparian areas, beach fringe, and estuaries). Therefore, Alternatives 4 and 7 are the most likely to adversely affect brown bears by reducing the amount of roadless refugia secured from timber harvest, which could prevent access to important habitats, impede movement through corridors, and increase the risk of over-harvest and DLP mortality.

Road densities are another measure of the potential impact of the alternatives on brown bears. Primary concerns include increased hunting or poaching, and disturbance during critical life stages (e.g., late-summer feeding periods for bear). Habitat fragmentation, as well as habitat loss secondary to activities that are facilitated by vehicular access (e.g., timber harvest, mining, residential development) are other potential impacts. Open roads, which receive the highest and most consistent use, are likely to have the greatest effect on brown bears, although closed roads still facilitate access (e.g., off-highway vehicle, pedestrian) to roadless areas. There is no road density threshold for brown bears, per se, however it can be assumed that increased road density elevates the potential for human-bear interactions.

Road density was evaluated by WAA in ADF&G GMU 4, which includes Admiralty, Baranof, Chichagof, Kruzof, Yakobi, and neighboring islands, and is the only island group in Southeast Alaska with a persistent, high density population of brown bears. Current road densities (all roads included) are highest on Chichagof Island, Northeast Chichagof Island, and North Kruzof Island. These WAAs are likely to experience the greatest cumulative effects of road access (increased potential of human-bear interactions) associated with increased road density. They are also where the greatest increases in road density are proposed under the alternatives. Within these higher risk WAAs, road density increases would be greatest under Alternative 7, followed by 4, 5, 6, 3, 2, and 1; one exception is WAA 3311 where road density would only increase under Alternatives 4, 5, 6, and 7. There are also two WAAs on Baranof Island (3314 and 3315) that could become areas of higher risk under all alternatives;no road density increases would occur under any of the alternatives on Admiralty Island.

Alexander Archipelago Wolf

Two principal management concerns associated with maintaining well-distributed and viable wolf populations in Southeast Alaska are that 1) current mortality rates in localized areas such as north Prince of Wales Island (POW), may result in local declines in the wolf population, and 2) long-term reductions in deer habitat capability resulting from timber harvest may negatively affect wolf populations (Interagency Wolf Conservation Assessment; Person et al. 1996). Though wolves exploit a variety of food resources across the Tongass, deer are their primary prey and predator/prey interactions between wolves and deer have been demonstrated to be implicitly linked to wolf persistence. That is, if deer habitat capability in a territory is reduced to such an extent that it can no longer support a reproductively successful pack, it could create a gap in wolf distribution, particularly on islands that experience a substantial decline in deer numbers, or result in a lower density wolf population with larger pack home range sizes (Mech et al. 1998, Person et al. 2001, Fuller et al. 2003). This concept was identified as the most important factor limiting wolf viability by the 1997 Forest Plan panel assessment. Recent research (*Alexander Archipelago Wolf*, presented at the Tongass Conservation Strategy Review Workshop 2006) has shown that the population on POW Island is genetically isolated from other Tongass populations, which presents profound implications for maintaining well-distributed wolf populations in light of local declines, given that these populations are are more sensitive to human activity and habitat disturbance than wolf populations elsewhere in the state (Schoen and Person 2007). Local declines on POW Island have been linked to the influence of road densities that provide greater trapping and hunting access to significant proportions of the wolf range, which increases wolf vulnerability to both legal and illegal mortality. The following analysis focuses on GMUs 2 and 3, which support 60 to 70 percent of the wolf population in Southeast Alaska.

To address impacts to wolves, the potential effects of the alternatives on the availability of deer to wolves were evaluated. Though prediction of the response of the wolf population to changes in the deer population is speculative at best, a decline in the deer population would likely result in a decline in the wolf population and a reduction in wolf density. Resonating effects could include reductions in opportunities to harvest wolves. The Wolf standards and guidelines state that habitat to support a density of 18 deer per square mile is necessary to provide wolves and hunters with adequate foraging/hunting opportunities (see TPIT clarification letter regarding correct interpretation of deer density stated in Wolf standards and guidelines and additional discussion below regarding subsequent modification). This density does not represent actual population density and is not related to wolf viability, but represents the functioning of the predator-prey system dynamic. Although the Tongass and the ADF&G conduct limited deer pellet surveys to estimate deer population trends, robust deer density estimates are not available for the Tongass because surveys are conducted in a very limited number of areas (they focus on areas with heavy hunting pressure) and are inconsistently conducted from year to year. Given these limitations, impacts to actual deer density cannot be quantified per se; however, some generalizations can be made about the effects of changes in habitat capability on deer numbers if information about current population trends is known.

It can be assumed that the carrying capacity for deer, or the maximum population size that a given area can support, influences how a deer population might react to changes in habitat capability. That is, if habitat capability were substantially reduced in an area, a deer population may simply slow in growth or stabilize if the population is below carrying capacity, or it may dramatically decline if it is at, or exceeding, carrying capacity because resources would no longer be adequate. This in turn relates to the influence of wolf predation on the deer population in that predation can be compensatory if the population exceeds carrying capacity (i.e., wolves kill deer that normally would have died of starvation), or additive if the population is below carrying capacity (i.e., wolves kill healthy deer that normally would have survived the winter). In the latter case wolf predation may contribute to a locally declining deer population and may actually suppress recovery of deer populations following severe declines (Person et al. 1996, Person 2001, Bowyer et al. 2005). This effect is sometimes referred to as a predator pit. For example, the slow rebound in the deer population on some of the south central islands in the Alexander Archipelago following severe winters in the late 1960s and early 1970s have been attributed to a combination of factors, including several severe winters, low-quality winter deer habitat in some locales (such as Kupreanof Island), and predator suppression (Kirchhoff 2003). Clearly, deer populations and the ability of a habitat to support deer are influenced by a myriad of factors not accounted for in this comparison. Weather, hunter effort, current deer population trends, allowed hunting pressure, and the presence of other predators are some of the factors that influence deer numbers and the magnitude of impacts related to changes in habitat capability. Moreover, there are time-lag effects associated with changes in habitat capability.

The 2005 ADF&G deer management report provides general information on deer population trends by GMU (Porter 2005, Lowell 2005). Both GMU 2 and 3 populations have historically fluctuated with the most severe declines having been associated with winter weather; however predation and illegal harvest have extended these declines. Current ADF&G management goals, which are to increase population levels in these units, indicate that deer populations are below carrying capacity. Deer populations in GMU 2 are reported to be at moderate levels but expected to decline; deer populations in GMU 3 are reported to be stable with some localized variation. Continued logging is anticipated to result in a decrease in carrying capacity over the long-term due to reductions the amount of available winter range. In GMU 2 a reduction in carrying capacity of up to 60 percent has been projected (Porter 2005). This means that over the long-term reductions in habitat capability could cause deer numbers to decline, reducing the number of deer available to wolves.

Timber harvest of important deer winter range reduces modeled deer habitat capability over the long term. Immediate concerns with all action alternatives focus on the cumulative effects of past timber harvest on the reduction in deer habitat capability on Prince of Wales and Kosciusko Islands (GMU 2), where a substantial amount of harvest has already occurred. In the 25 WAAs on Prince of Wales and Kosciusko islands, reductions in deer habitat capability would be greatest under Alternatives 4 and 7. Alternatives 1, 2, 3, and 6 would result in an equal or smaller reduction in deer habitat capability on these islands than Alternative 5 (No Action) (Table 3.10-7). The risk of not sustaining a well distributed, viable wolf population increases under Alternatives that have multiple WAAs within a single biogeographic province where large reductions in deer habitat capability would occur and where deer habitat capability is already low, but would be further reduced (e.g., WAAs on North Central Prince of Wales and South Prince of Wales biogeographic provinces). In several cases, deer habitat capability under Alternative 7 would be reduced to below 40 percent of that existing in 1954 prior to large-scale timber harvest. Of the 16 WAAs on Kuiu, Kupreanof, and Mitkof islands (GMU 3) maximum estimated reductions in habitat capability range from 2 to 47 percent. Risks to wolves would be slightly lower on these islands due to the lower level of planned timber harvest.

An index of the ability of the alternatives to support deer populations capable of maintaining sustainable wolf populations and meeting human harvest demands can also be approximated by using the deer habitat capability model to project habitat capability in terms of deer density (i.e., the number of deer per square mile an area may be capable of supporting) for comparison with the Wolf standard and guideline described above. In the wolf conservation assessment (Person et al. 1996), a population density of 13 deer per square mile, was recommended to maintain sustainable wolf populations, assuming an annual deer reproductive rate of 30 percent. This equates to approximately 17 deer per square mile at carrying capacity (Person et al. 1996). That is, to provide for a population of 13 deer per square mile there needs to be an average long-term habitat capability of 17 deer per square mile over broader areas. This number was later revised to the current value of 18 deer per square mile as stated in the standard and guideline. It must be emphasized that these model outputs do not represent actual deer densities and cannot be used to predict changes in the prey base available to wolves and hunters, rather they are intended as one method of making relative comparisons among the alternatives. At the project level, other factors such as local knowledge of habitat conditions, spatial location of habitat, and other site-specific information need to be considered

Based on ADF&G recommendations, habitat capability in terms of deer density was calculated by assuming a density of 100 deer per square mile for an HSI of 1.0. Only WAAs where wolves potentially occur (GMUs 1, 2, 3, and 5) were included. Table 3.10-9 shows long-term wolf habitat capability in terms of deer per square mile.

The Wolf guideline is intended to apply to biogeographic provinces where deer are the primary prey of wolves. Thus, the number of WAAs that appear to fall below 18 deer per square mile in terms of habitat capability is inflated because many either do not naturally contain much suitable deer habitat or are areas where wolves also prey heavily on species other than deer such as moose, beaver, or mountain goats. All of the alternatives increase the number of WAAs that do not maintain habitat capable of supporting 18 deer per square mile, the greatest number being added under Alternative 7, followed by Alternatives 4, 5/6, 3, 2, and 1, respectively. Most of the WAAs that currently meet the Wolf guideline, but may not meet it in the future after 100+ years of implementation, are located in the North Central Prince of Wales and Revilla Island/Cleveland Peninsula biogeographic provinces.

Table 3.10-9.
Comparison of Alternatives in terms of their Long-term Ability to Meet the Wolf Guideline of Providing Sufficient Habitat to Support 18 Deer per Square Mile after 100+ Years of Forest Plan Implementation [1]

	Increase in Percent of WAAs, Relative to 1954 Conditions, with Model-generated Habitat Capability <18 Deer/Sq. Mi. [2]	Biogeographic Provinces of WAAs Affected by Implemention of the Alternatives [3]
1954 Conditions[4]	--	-
Current Conditions	+12%	-
Alternative 1	+16%	14, 15
Alternative 2	+17%	11,14, 15, 18
Alternative 3	+25%	11, 14, 15, 18
Alternative 4	+22%	9, 10, 11, 12, 14, 15, 18, 20
Alternative 5	+22%	9, 10, 11, 12, 14, 15, 18, 20
Alternative 6	+22%	9, 10, 11, 12, 14, 15, 18, 20
Alternative 7	+25%	9, 10, 11, 12, 14, 15, 18, 20

[1] Assumes full implementation of Forest Plan at ASQ levels.

[2] Excludes WAAs where wolves do not occur (Admiralty, Baranof, and Chichagof islands and associated small islands) and WAAs with naturally very low deer densities (WAAs 4302-4607). Habitat capability in terms of deer density calculated using a multiplier of 100 deer per square mile equating to a habitat suitability index score of 1.0.

[3] Biogeographic Provinces: 9 = Northern Coast Range; 10 = Kupreanof/Mitkof Island; 11 = Kuiu Island; 12 = Central Coast Range; 14 = North Central Prince of Wales; 15 = Revilla Island/Cleveland Peninsula; 18 = South Prince of Wales; 20 = South Misty Fiords (some WAAs may overlap more than one biogeographic province)

[4] Approximately 69 out of 122 WAAs (57%) were estimated to have had deer habitat capabilities <18 deer per square mile in 1954.

As noted above, human access on roads may result in wolf mortality by both legal and non-legal harvest. Therefore, road densities are a factor to consider in sustaining wolf populations. Person et al. (1996) suggested that roadless and unfragmented reserves should be established in biogeographic provinces where extensive timber harvesting is planned to reduce long-term risks to wolf viability. Reserves of approximately 50,000 acres for each 192,000 acres of landscape area were considered necessary to support relatively secure core wolf populations. Spacing among reserves was not a critical criterion due to the extensive movement capability of wolves. The 1997 Forest Plan established habitat reserves in excess of this amount in Prince of Wales/Kosciusko islands and Kuiu/Kupreanof/Mitkof islands, including one reserve greater than 200,000 acres in size in the North Central Prince of Wales biogeographic province. Based on reductions in deer habitat capability and the existence of roadless refugia, Alternative 11 in the 1997 Final EIS (Alternative 5 here) was determined to meet the reserve criteria identified by Person et al. (1996) and was ranked as having a high likelihood of sustaining persistent core wolf populations and reducing risks to long-term viability in the two principal areas of concern in Southeast Alaska (GMU 2 and 3) as well as the remainder of the historic wolf range on the Tongass (Iverson 1997c, 1996c) (Appendix D). Alternatives 3, 4, and 6 would also be rated high (Appendix D). Given the higher level of timber harvest and reduction of the Old-Growth Habitat

LUD under Alternative 7 would have a moderately high likelihood of maintaining well-distributed, viable wolf populations.

The current Wolf standards and guidelines state that “where road access has been determined through analysis to significantly contribute to wolf mortality…open road densities of 0.7 to 1.0 mile per square mile or less may be necessary to reduce mortality to sustainable levels.” This metric is appropriately applied at the project level to areas that are the approximate size of an average wolf pack territory (about 74,000 acres; Person et al. 1996). For this analysis, total road densities were calculated by WAA, the average size of which is 90,000 acres. Thus, road densities reported here are likely slightly lower than what could actually be experienced within a wolf pack territory. Currently, out of the 54 WAAs in GMUs 2 and 3, there are 19 WAAs with total road densities greater than 1.0 mile per square mile (including both NFS and non-NFS lands). After full implementation of the Forest Plan (100+ years), the total number of WAAs where this is exceeded would be greatest under Alternative 7 (30 WAAs), followed by Alternatives 4 (29 WAAs), 5 and 6 (28 WAAs), 3 (27 WAAs), 2 (25 WAAs), and 1 (23 WAAs) Although additional research is needed to determine whether or not a direct correlation exists between local wolf population dynamics and road density, research indicates that the likelihood of maintaining viable wolf populations would be lowest in areas that have the highest road densities, due to higher trapping and hunting harvest rates (*Alexander Archipelago Wolf*, presented at the Tongass Conservation Strategy Review Workshop 2006), though this is situation-specific in that it depends on how accessible roads are (i.e., whether they are near main road systems or human settlements). In addition, harvest levels can be controlled through regulations. However, Alternatives 4 and 7, in increasing order, would be most likely to result in increased harvest pressure and illegal mortality associated with higher road densities. However, if a viability concern emerged, there are other Forest-wide standards and guidelines in place that would mitigate road-related effects including road closures that effectively prohibit motorized vehicle traffic (e.g., bridge and culvert removal) and off-highway vehicle restrictions.

Bald Eagle

Bald eagles primarily nest in old-growth trees along the coast and within riparian areas. Over 90 percent of the known nests on the Tongass are within 50 feet of the saltwater beach. The Bald Eagle and Riparian Forest-wide standards and guidelines are specifically designed to protect nesting habitat and the current Forest Plan includes 1,000-foot beach and estuary buffer requirements. The amount of nesting habitat in OGRs, non-development LUDs, and the 1,000-foot beach and estuary buffer protects virtually all bald eagle nesting habitat on the Tongass. All of the action alternatives considered here would maintain these standards and guidelines and provide the same level of protection as the current Forest Plan, with the exception of Alternative 7, which proposes to reduce the beach fringe buffer to 500 feet. Therefore, only slight effects to bald eagles are expected under Alternatives 1, 2, 3, 4, 5, or 6. Under Alternative 7, protection of bald eagle nests occurring beyond 500 feet from saltwater would be reduced to the required 330-foot nest buffer, which would limit protection of nesting habitat to the area around known nests. This would reduce the overall amount of habitat potentially available for nesting in areas where road construction and harvest occur.

Red-breasted Sapsucker, Hairy Woodpecker, Brown Creeper, and Red Squirrel

These species rely on legacy components (e.g., large diameter trees, snags) of the old-growth forest ecosystem for nesting and foraging. A simple index of the level of habitat protection provided by each alternative is the amount of suitable old growth schedule to be harvested. After full implementation of the Forest Plan, the greatest percentage of existing POG could be harvested under Alternative 7 (16 percent), followed by Alternative 4 (13 percent), Alternatives 5 and 6 (9 percent), Alternative 3 (6 percent), Alternative 2 (4 percent), and Alternative 1 (2 percent) (see Table 3.10-5). Thus, Alternatives 7, 4, 5, 6, 3, 2, and 1 would have an increasingly greater chance of maintaining habitat capable of supporting well distributed, viable populations of these species.

Under Alternative 5 (No Action), non-development LUDs provide broader protection for old-growth forest, where as Reserve Tree/Cavity-nesting Habitat, Goshawk Foraging, and Marten Habitat standards and guidelines provide protection to old-growth habitat components within matrix lands. The application of two-aged and uneven-aged management under Alternative 5 provides further habitat protection for these species. The current Goshawk and Marten standards and guidelines are applied to areas of the Forest with the greatest amount of disturbance. Although the new Legacy standard and guideline proposed under Alternatives 1, 2, 3, and 6 would affect less overall area, it would be applied on a Forest-wide basis and require that retained trees and snags be representative of the existing stand age, species composition, and structural components (Appendix D). In contrast, neither the Goshawk Foraging, the Marten Habitat, nor the new Legacy Forest Structure standards and guidelines would be implemented under Alternatives 4 and 7. Therefore under these alternatives there would be no quantitative direction for the retention of structure, and consequently, together with the higher rate of harvest, Alternatives 4 and 7 would have greater effects on these species.

Vancouver Canada Goose

Vancouver Canada geese use wetlands (forested and non-forested) in the estuary, riparian, and uplands areas of the forest. Habitat needs for these species are specifically provided for under the waterfowl standards and guidelines, which apply to specific sites, and a 100-foot buffer around lakes or streams. The beach, estuary, and riparian Forest-wide standards and guidelines provide additional protection to habitats used by Canada geese. Consequently, there is no increased risk of habitat loss associated with any alternatives considered under this Forest Plan amendment, with the exception of Alternative 7, which proposes to reduce the beach fringe buffer to 500 feet and could result in the loss of suitable habitat in areas outside of this buffer if timber harvest and associated activities occur.

Other Species of Concern

Marbled Murrelet

Distributional and ecological information about marbled murrelets in Southeast Alaska is largely lacking but high value habitats appear to be those found within large, contiguous blocks of high volume, low-elevation old-growth forest. Fragmentation and loss of overstory cover are two threats associated with development activities, such as timber harvest, that are correlated with increased predation. Alternative 11 of the 1997 Forest Plan Final EIS (Alternative 5 here) was determined to provide a very high likelihood of sustaining well distributed murrelet populations throughout Southeast Alaska due to the reserve system, which includes at-risk landscapes with high levels of past timber harvest, as well as beach and riparian protection.

Alternative 7 proposes to harvest the greatest amount of existing POG (16 percent), and thus provides the least protection to marbled murrelets due to direct habitat loss and fragmentation and the limited reserve system. This is followed, in decreasing order of potential impacts, by Alternative 4 (13 percent), Alternatives 5 and 6 (9 percent), Alternative 3 (6 percent), Alternative 2 (4 percent), and Alternative 1 (2 percent) (Table 3.9-5). Alternatives 1, 2, 3, 5, and 6 would be judged as having a very high likelihood of maintaining viable and well distributed marbled murrelet populations, Alternative 4 was judged high, and Alternative 7 was judged moderately high (Appendix D).

Spruce Grouse

Spruce grouse have historically inhabited forests showing a disturbance-related patchwork of various stages of regeneration. Timber harvest can produce similar patterns, but only if clearcut areas are small and if sufficient quantities of forested habitat are preserved. Spruce grouse inhabit some of the most highly modified landscapes on the Tongass (e.g., Prince of Wales Island) where additional timber harvest could threaten the long-term survival of these highly isolated and scattered low-density populations. This has particularly important conservation implications since the subspecies that occurs in Southeast Alaska is endemic. Conservation measures including a system of non-development LUDs and standards and guidelines that maintain connectivity within matrix lands (e.g., various buffer requirements) are essential to facilitating dispersal and interchange between isolated populations. Spruce grouse are also vulnerable to hunting and exploitation, correlated with road access, because they are not wary of humans, though viability is not an immediate concern given the level of harvest permitted in this area.

Spruce grouse are an important prey species for goshawks and marten. In a study of goshawk diet during the breeding season in Southeast Alaska, birds (including spruce grouse) comprised a larger proportion of goshawk diet on Prince of Wales Island than elsewhere due to the limited number of prey species, many of which are sensitive to timber harvest activities (Lewis et al. 2006). This study concluded that the ability of goshawks to successfully reproduce in Southeast Alaska and on Prince of Wales Island in particular, appears to be affected by the extensive landscape alteration in this region in combination with the restricted prey base. Thus, alteration of spruce grouse habitat could have a resonating effect on predator populations.

Given the current level of habitat modification in areas of the Tongass occupied by spruce grouse, the greatest protection would be provided by alternatives that propose the least amount of POG harvest and those with provisions for maintaining landscape connectivity. As described above under the marbled murrelet analysis, the greatest amount of habitat protection would be provided by Alternative 1, followed by Alternatives 2, 3, 6, 5, 4, and 7. Alternative 1, 2, 3, and 5, also include the most measures for maintaining landscape connectivity through the existing system of OGRs, where as Alternatives 4 and 7 reduce or eliminate the OGR system, respectively. Thus the alternatives in this order would have a decreasing likelihood of sustaining spruce grouse populations capable of providing an adequate prey base for goshawks and other predatory species and sustaining current levels of harvest.

Prince of Wales Flying Squirrel

Given that flying squirrel density in Southeast Alaska is highest in POG and closely tied to the abundance of large trees and snags, and that timber harvest occurs in forests where these habitat components are most abundant, the number of acres suitable for timber harvest is an appropriate measure of the relative effects of the alternatives on this species. The recent research described in the Affected Environment indicates that this risk is likely less than presumed because abundant noncommercial forests appear to contribute to breeding populations. Alternative 7 proposes the most acres of harvest, followed by Alternatives 4, 5, 6, 3, 2, and 1 (see Table 3.10-5 and the Marbled Murrelet discussion above). In addition to decreasing the abundance of these habitat components, timber harvest can also create openings that may be too large for flying squirrels to travel through, resulting in smaller, isolated populations that may be at risk of local extirpation. Consequently, a system of OGRs and retention requirements for forest legacy components are important for sustaining well distributed populations of flying squirrels.

Alternative 5 maintains the existing system of OGRs and Goshawk Foraging and Marten Habitat standards and guidelines that apply reserve tree requirements to matrix lands in the highest risk biogeographic provinces that have experience the highest cumulative effects of timber harvest (e.g., North Central Prince of Wales). Alternatives 1, 2, 3, and 6 also maintain the Forest-wide reserve system and replace the Goshawk Foraging and Marten standards and guidelines with the Forest-wide Legacy Structure standard and guideline; Alternatives 4 and 7 provide less protection because they include more area in development LUDs and do not include any of these standards and guidelines (see discussion under Red-breasted Sapsucker, Hairy Woodpecker, Brown Creeper, and Red Squirrel). In addition, Alternative 4 limits the OGR system to four of the most heavily logged biogeographic provinces, one of which is North Central Prince of Wales, and thus is not anticipated to affect Prince of Wales flying squirrels in that respect. Alternative 7 eliminates the Old-Growth Habitat LUD entirely. Consequently, Alternative 7 would have the greatest risk of creating isolated populations of flying squirrels susceptible to local extirpation both directly through habitat removal and through increased fragmentation by not incorporating provisions intended to maintain landscape connectivity.

Migratory Birds

Direct habitat and disturbance related effects to migratory birds would occur under all of the alternatives. The primary effect to birds would be nest destruction or abandonment if management activities occur in suitable nesting habitat during the breeding/nesting period, which generally begins in May and ends in September when young birds have fledged. The magnitude of the effects will vary depending on the alternative that is selected and the season in which disturbance would occur. It can be assumed that species most likely to be affected are those that nest in hemlock/Sitka spruce forests (e.g., blue grouse, rufous humming bird, and Pacific-slope flycatcher) where timber harvest occurs, and thus the amount of harvest proposed under the alternatives is a measure of the extent of potential effects.

Alternative 7 would remove the most POG after full implementation of the Forest Plan (roughly 100+ years) followed in descending order by Alternatives 4, 6, 5, 3, 2, and 1, respectively. Total percentage of POG harvest would range from 16.7 percent of existing POG under Alternative 7 to 1.7 percent of existing POG under Alternative 1. In addition, Alternatives 1, 2, 3, 5, and 6 include some provisions for retaining additional legacy forest structure either through the existing Goshawk Foraging, Marten Habitat, and Cavity-nester standards and guidelines (Alternative 5), or through a Forest-wide Legacy Structure standard and guideline. Therefore, these alternatives would provide more available legacy structure to migratory birds for nesting, roosting, and foraging than Alternatives 4 and 7, which do not include any legacy retention requirements.

Other effects of timber harvest and associated activities include the fragmentation and patch size reduction of suitable habitat. For species such as the varied thrush and Townsend's warbler, habitat removal would potentially reduce the effectiveness of interior habitat and increase the potential for nest-site predation from avian predators that are associated with forest edges and fragmented landscapes. The Conservation Strategy was designed to retain large blocks of old-growth distributed across the Forest, such that interior nesting habitat would be retained across the landscape. In addition, other retention in the matix, including the 1000' beach and estuary buffer, benefits migratory birds and mitigate negative effects of fragmentation in the matrix. Therefore, effects to species associated with interior forest conditions would be greatest under Alternatives 4 and 7, in increasing order, because they reduce or eliminated the OGR system, respectively. Effects to other species that are more closely associated with forest edge, riparian, or more open habitats would likely be negligible under Alternatives 1, 2, 3, 4, 5, and 6, which maintain species-specific and/or Forest-wide standards and guidelines that provide protection measures for key habitats (e.g., beach, estuary, and riparian buffers). However, the beach fringe buffer would be reduced to 500 feet under Alternative 7, thus decreasing the amount of protected nesting habitat in these areas and reducing the amount of interior habitat available. Some species, particularly those associated with edge habitats, may benefit from timber harvest proposed under any of the alternatives due to the creation of new habitat. Greatest adverse impacts to migratory birds would occur in the four most heavily disturbed biogeographic provinces where a majority of future timber harvest is concentrated (e.g., North Central Prince of Wales Island, Kupreanof/Mitkof islands, Revillagigedo Island/Cleveland Peninsula, and Etolin Island provinces).

Endemic Mammals

The 1997 Forest Plan Final EIS panel assessments evaluated 14 species or subspecies endemic to Southeast Alaska (Shaw and Smith 1995, Iverson 1997b). All of these species occupy restricted ranges, limited to a subset of islands in Southeast Alaska. Under the current Forest Plan all islands less than 1,000 acres were removed from the timber base to eliminate risk to these species associated with habitat loss or alteration from timber harvest. The 1,000-foot beach buffer, riparian corridors, and OGR system are also features of the current Forest Plan that provide functional habitat for species with relatively small home ranges. In addition, implementation of various standards and guidelines that apply within matrix lands will result in significant old-growth retention, which also benefits many endemic mammals. These protective provisions would be maintained under all the alternatives, with the exception of Alternative 7 under which the beach fringe buffer would be reduced to 500 feet and the system of OGRs eliminated.

The panel assessments emphasized that just being an endemic represented a naturally elevated viability risk and that all alternatives had some likelihood of causing extirpation of endemic species based on historical and proposed timber harvest activity and that this likelihood increased with higher levels of proposed harvest. This is consistent with recent science suggesting that the areas of greatest conservation concern in the Alexander Archipelago are biodiversity hotspots (i.e., areas where multiple endemic mammal lineages occur), many of which coincide with the most heavily impacted areas (Cook et al. 2006). Based on the 1997 expert panel assessments for endemics (Iverson 1997b), it can be concluded that Alternative 5 (which is the equivalent of Alternative 11 in the 1997 Forest Plan Revision Final EIS) and Alternative 6, which proposes to harvest slightly less timber, would have a moderate likelihood of sustaining viable, well-distributed populations of endemic mammals (Appendix D). Alternatives 1, 2, and 3, which propose to harvest less timber than Alternatives 5 and 6, would only build on the above scenario, but also would be ranked as having moderate likelihoods of sustaining viable, well-distributed populations of endemic mammals over the long-term. Because of the level of past harvest, the panel also rated a no-harvest alternative as having a moderate likelihood

Based on the expert panel assessments (Shaw and Smith 1995, Iverson 1997b) Alternative 4 (equivalent to Alternative 6 in the 1997 FEIS) would be rated as having a moderately low likelihood of maintaining viable, well-distributed populations of endemic mammals given proposed harvest levels. Alternative 7 (equivalent to Alternative 2 in the 1997 FEIS) would have a very low likelihood of sustaining well-distributed, viable endemic populations, and would have the highest likelihood among the alternatives to result in endemic populations that exist only in refugia (e.g., northern flying squirrel) or become extirpated (e.g., Keen's myotis).

Invasive Species

Although a number of non-native wildlife species have been accidentally introduced or transplanted in Southeast Alaska, the only species considered invasive (i.e., based on the definition that they cause harm to the economy, environment, or humans) at the present time is the Norway rat; elk in Southeast Alaska may be considered invasive in certain geographic areas due to their effects on habitat in areas to which they were not intentionally introduced. Although the current Forest Plan does not specifically address invasive species, its intent is to manage for native species, as evidenced by the Goals of the Forest Plan, and in the Biodiversity and Forest Health sections, albeit these sections emphasize invasive plants.

At the time of this writing, none of the alternatives propose changes to the management framework of the Tongass in relation to invasives and neither the Norway rat nor elk are addressed under the Forest Plan Monitoring section or standards and guidelines. However, the Alaska Region of the Forest Service is currently developing an invasive species strategy that will apply the principles of prevention, early detection, control, and rehabilitation in cooperation with various agencies and partners.

Activities that create or enhance the habitats preferred by invasive species may facilitate range expansion. This premise can be used as a measure of how the alternatives potentially contribute to, or reduce, the invasive species problem. Norway rats inhabit coastal habitats where the main cause of range expansion, or source of new introductions, is shipping activity. Management activities on the Tongass have no effect on shipping activity and therefore will not influence the occurrence of Norway rats.

In contrast, elk in Southeast Alaska have similar habitat requirements to black-tailed deer and therefore may benefit from habitat enhancement resulting from timber harvest. Timber harvest has been a precursor to both deer and elk population expansions in many parts of the western United States, due to the resulting increase in forage. Although, forest management activities on the Tongass will have no influence on the ability of elk to move between islands, they may affect the success of elk in colonizing new islands, particularly those in the vicinity of Zarembo and Etolin Islands where elk sightings are becoming more frequent, or the likelihood of expanding their distribution on larger islands where smaller populations exist.

Elk, like deer, require a mosaic of habitat types for foraging, finding shelter, and obtaining security from predators and humans. Timber management activities that create gaps in the forest canopy create a favorable environment for the establishment and growth of early seral vegetation, thus increasing the abundance and variety of forage available to elk (Skovlln et al. 1989). However, because of their wariness, elk generally forage in proximity to hiding cover and are not likely to use the interior areas of large gaps due to the lack of accessible cover (Thomas 1979). Elk have also been shown to avoid ongoing road construction and timber harvest, using adjacent areas of cover (e.g., late seral stands) until the conclusion of these activities. Therefore, over the short-term, elk will likely avoid areas of proposed timber harvest activities while activities are ongoing. However, over the long-term all of the alternatives have the potential to promote elk establishment in areas where they propose timber harvest. However, the extent to which this affects the expansion of the elk population is dependent upon the timing and location of timber harvest and associated activities. It is important to note however, that elk are a desired non-native species on Zarembo and Etolin islands where they were introduced. The Forest Service and ADF&G are working collaboratively to identify research needs including determining existing population levels and documenting the distribution of elk on these islands and elsewhere.

Alternate Risk Assessment Method

To determine whether the alternatives provided sufficient habitat to sustain all indigenous wildlife across the planning area the Forest Plan FEIS relied in part on the findings of structured panel assessments. As described above these panel assessments provided estimates of the relative risk, in the form of a probability, that implementating the range of management alternatives would pose to the continued persistence across the landscape of an array of species. Scores from individual panel members were averaged to assign probabilities to 5 possible outcomes related to population distributions: occupancy of historic range (Outcome I), temporary gaps in distribution (Outcome II), permanent gaps in distribution (Outcome III), existence in refugia (Outcome IV), and local extirpation (Outcome V).

Recently, Smith and Zollner (2005) argued that using the most vulnerable species to assess impacts of land management likely underestimates the probability of extinction of wildlife species across the planning area because the risk of local extirpation increases with the number of extinction prone species considered. Additionally, the management alternative that poses the greatest risk to the most vulnerable wildlife species may not pose the greatest risk to the wildlife community as a whole (Smith and Zollner 2005). The authors present an alternative method for assessing risk to wildife viability that considers the risk of “any” extinction among species at risk in the planning area. To accomplish this, an equation is used which calculates the joint probablitity of at least one extinction among the set of selected species to compare the relative, rather than absolute, risk of extinction among land management alternatives (see Appendix D and Smith and Zollner (2005) for the equation and for statistical details).

This method was used to rank the current alternatives in terms of relative level of viability risk, in order to consider an alternate method for risk assessment. The likelihood scores assigned by the 1995/96 and 1997 expert panels were used to develop the index. Section 3.6 in Appendix D presents the results of this alternate risk assessment for Alternatives 4, 5, 6, and 7, which are the alternatives most easily related to the alternatives assessed by the risk assessment panels.

Applying this risk assessment method indicates that, when all evaluated species are considered jointly, Alternatives 4 and 7 would have the greatest risks. This difference is driven primarily by potential risks to the endemic and widely distributed mammals groups, which have the highest risks of any species or group evaluated (Appendix D). The risk index was substantially lower for Alternatives 5 and 6. Because Alternatives 1, 2, and 3 would harvest less timber than Alternative 5 or 6, but maintain equivalent or more protective conservation measures, their risk indices would likely be lower than the corresponding indices for Alternatives 5 and 6. As expected based on harvest acres, the lowest risk indices would be associated with Alternative 1.

Monitoring and Evaluation Program

One facet of the Forest Plan amendment is a rigorous review of the Monitoring and Evaluation Program, including the MIS approach. As noted above, the MIS concept allows a manageable subset of species, whose response to land management activities can be used to predict the likely response of other species with similar habitat requirements, to be used in planning. Consistent with planning regulations under the NFMA, the Tongass has selected the list of 13 MIS described above and has developed monitoring strategies for each species to track population trends.

Forest Plan Standards and Guidelines narrow the selection of suitable indicator species to emphasize management for indigenous wildlife species and natural habitat (WLD112 I(B)), and to provide the abundance and distribution of habitat necessary to maintain viable populations of existing native and desirable introduced species well distributed in the planning area (WILD112 II(B)). To achieve this, the MIS monitoring effort has been designed to determine if population trends for MIS and their relationship to habitat changes are consistent with expectations.

An assessment of monitoring data collected since 1997 indicates several shortcomings. First, monitoring data are not collected at a scale, or with sufficient statistical rigor, to determine population status or trends for an area as expansive as the Tongass. Moreover, due to the inherent difficulty of monitoring many species, which is a fundamental problem underlying the MIS approach on the Tongass, data are derived from the best available sources, yet they are generally not appropriate for answering specific forest management monitoring questions. That is, they are not useful in identifying a link between habitat modification and population trends. Thus, there are few species actually able to provide insight into whether or not the Conservation Strategy is meeting wildlife objectives, as established by the Forest Plan. One challenge related to this is that limited funding may preclude the development of new monitoring strategies, or may be insufficient to support an increase in monitoring efforts to improve statistical rigor. It is important to note however, that these problems are not unique to the Tongass, as many national forests are evaluating their MIS lists, as well as the value of the MIS approach in general.

One potential option for revising the Monitoring and Evaluation program under consideration is to shift the focus to a select number of 'focal' species that could be more intensively monitored. These species would likely be those that are most easily monitored, have the greatest economic and/or cultural value, or whose viability is of greatest concern. Another approach would be to use surrogate measures for monitoring impacts to species of concern, such as habitat characteristics (e.g., snag abundance) or prey species, which may be more conducive to monitoring. For example, focusing monitoring efforts on red squirrels, and establishing a relationship between their population trends and habitat modifications, may provide a better insight as to how management activities are affecting marten and goshawks than actually surveying for these species. The redesignation of MIS for the Tongass is continuing to be evaluated and new MIS are not being proposed at this time. Broader adjustments to the proposed Monitoring and Evaluation Program have been incorporated into the accompanying Forest Plan.

Cumulative Effects

Activities that occur on other land ownerships within and adjacent to the Tongass have the potential to affect the overall context within which effects of Forest management on wildlife population distribution and viability are considered. Such reasonably foreseeable activities include, but are not limited to, timber harvest, residential development, mining, recreation and tourism, and road construction. Typically these activities have the potential to negatively impact wildlife populations through habitat conversion, fragmentation, and disturbance associated with road building, though some activities can have short-term or long-term beneficial impacts, depending on the species (i.e., improved forage quality and quantity for deer following timber harvest). Prediction of the future extent and intensity of such activities has a high degree of uncertainty associated with it on a Forest-wide basis over a broad time scale. As such, cumulative effects associated with specific projects are most appropriately assessed at the project level. Therefore, this analysis will examine effects associated with general trends in activities on non-NFS lands.

Many private lands in Southeast Alaska are already highly developed in terms of roading and timber harvest and are likely to experience a continuing decline in old-growth forest in the future. Therefore, the cumulative long-term trend within the Forest boundary under all alternatives is likely to be a decline in optimum habitat for most old-growth associated species, with non-NFS land contributing to this trend. When combined with other management activities occurring on non-NFS lands, all alternatives would produce additional impacts to some species, but to varying degrees. Cumulative effects are anticipated to be the greatest under Alternative 7, which proposes the highest amount of timber harvest, followed by Alternatives 4, 5, 6, 3, 2, and 1 in decreasing order, and would be most evident in areas where timber harvest is concentrated. Table 3.9-20 in the *Biodiversity* section summarizes the maximum long-term cumulative percent of the original POG that would be harvested in Southeast Alaska on all ownerships by biogeographic province. This table shows that the current cumulative past harvest on public and private lands equals 13 percent of all POG in Southeast Alaska (87 percent POG retention). Looking 100+ years into the future, cumulative POG harvest levels on all lands of Southeast Alaska would vary by alternative, ranging from 18 percent (80 percent POG retention) under Alternative 1 to 29 percent under Alternative 7 (71 percent POG retention). Under Alternatives 5 (no action) and 6 (proposed action), projected cumulative harvest levels would be 24 percent (76 percent POG retention). The highest rates of cumulative harvest would be in the North Central Prince of Wales biogeographic province (49 percent under Alternatives 5 and 6), Dall Island and Vicinity (45 percent under Alternatives 5 and 6), the Chilkat River Complex (44 percent under Alternatives 5 and 6), and Kupreano/Mitkof Island province (39 percent under Alternatives 5 and 6).

Cumulative harvest of high-volume and large-tree POG are summarized in Tables 3.9-21 and 3.9-22 of the *Biodiversity* section. These results show that because of historic disproportionate harvest, especially on private lands, the current cumulative past harvest of high-volume and large-tree POG in Southeast Alaska is estimated at 18 and 32 percent, respectively. Looking 100+ years into the future, cumulative high-volume POG harvest levels would again, vary by alternative, ranging from 25 percent (75 percent high-volume POG retention) under Alternative 1 to 35 percent under Alternative 7 (65 percent high-volume POG retention). Under Alternaties 5 (no action) and 6 (proposed action), projected cumulative harvest levels would be 30 percent (70 percent high-volume POG retention). Similarly, for large-tree POG, cumulative harvest levels would range from 38 percent under Alternative 1 to 48 percent under Altenative 7. Under Alternatives 5 and 6, projected cumulative harvest levels for large-tree POG would be 43 percent.

Evidence from theoretical and empirical studies suggests that the likelihood of a population persisting over time is related to some threshold level of habitat loss across the landscape (Fahrig 1997, 1999, 2003; Flather et al. 2002; Andren 1994). Haufler (2006) reviewed the literature and found that, based on modeling, habitat loss and reduction of population size are linearly related, up to some threshold. Below this threshold, the additional effects of habitat fragmentation increase the rate of population reduction, and in turn, the risk of extinction. Haufler (2006) also concluded that empirical studies provided support for this relationship.

Reported threshold levels for the percentage of habitat maintained at which the rate of landscape extinction increases range from 20 percent (Fahrig 1997) to 50 percent (Soule and Sanjayan 1998), depending in part on the dispersal capability of the species under consideration. In a modeling analysis, With (1999) demonstrated that landscape connectivity became a concern for species with some dispersal capability (e.g., wolves) when habitat was reduced to below 20 percent of the landscape, whereas when the landscape consisted of less than 40 percent habitat it became a concern for species with limited dispersal capabilities (e.g., flying squirrels). Natural fragmentation of habitats can also affect the level of additional fragmentation that can be supported.

None of the alternatives would result in less than 71 percent of the original POG remaining on the Southeast Alaska landscape after 100+ years. In addition, at least 51 percent of the original POG would be retained within each of the 23 individual biogeographic provinces under Alternatives 1, 2, 3, 5, and 6. Only under Alternatives 4 and 7, would this percentage fall below 50 percent, and then only in one province – North Central Prince of Wales (Table 3.9-20). Likewise, on a Southeast Alaska basis, none of the alternatives would result in less than 65 percent of the original high-volume POG remaining after 100+ years. At least 41 percent of the original high-volume POG would be retained in all 23 individual provinces under Alternatives 1, 2, 3, 5, and 6. In Alternatives 4 and 7, this percentage would decline to 39 and 33 percent in the North Central Prince of Wales province (Table 3.9-21). Finally, under each of the alternatives at least 52 percent of the large-tree POG would be retained over the entire landscape in Southeast Alaska after 100+ years. Under Alternatives 1, 2, 3, 5, and 6, this minimum percentage would range from 57 to 62 percent. For individual provinces, this percentage could drop as low as 31 to 33 percent in the East Baranof Island and Chilkat River Complex provinces under each of the alternatives, except Alternative 7 (Table 3.9-22). Under the latter alternative, the minimum percentage in the Kupreanof/Mitkog province could decline to 29 percent.

Although some wildlife species make higher use of the larger forest types defined by high-volume and large-tree POG, none of the wildlife species of concern are restricted to these habitats. In fact, all wildlife species make at least some use of types other than mapped POG (e.g., unproductive old-growth and older young-growth forests). Therefore, based on the reported habitat loss thresholds, it is unlikely that cumulative timber harvest would result in significant viability concerns for any species of wildlife in any of the provinces, except under Alternatives 4 and 7. The reduction of POG to below 50 percent in North Central Prince of Wales province, coupled with the greater reduction of larger forest types, would result in greater long-term viability concerns in this province under Alternatives 4 and 7. Under these alternatives, species with low dispersal capabilities, in particular, would have landscape connectivity concerns over the long term.

Additional effects, associated with the cumulative timber harvest described above, include road construction, which has the potential to impact wildlife species through habitat fragmentation, and access-related disturbance. Species that may be especially sensitive to this include forest interior species and large predators. Table 3.10-10 summarizes existing and proposed total (open and closed roads) road density by the number of WAAs within road density categories on NFS and combined (NFS and non-NFS) land ownerships. Generally road densities on private and state lands are greater than those found on adjacent NFS lands. In addition, there are no road closure/access management guidelines in place on these lands to reduce effects to sensitive species. The greatest cumulative road densities (NFS and non-NFS lands) would occur under Alternative 7, followed by Alternatives 4, 5 , 6, 3, 2, and 1. Maximum (i.e., proposed under Alternative 7) cumulative road densities would be greatest on Prince of Wales, Kupreanof, and Chichagof islands where a number of WAAs would exceed total road densities of 2 miles per square. Therefore the potential for habitat fragmentation, increased human access, and overharvesting of some species would be greatest under Alternative 7 followed by Alternative 4, followed by Alternatives 5, 6, 3, 2, and 1.

Cumulative habitat disturbance is especially problematic for archipelagos such as the Tongass, where habitat is already naturally fragmented among oceanic islands, average population size is smaller than in mainland habitats, source populations are isolated, and demographic stochasticity and inbreeding depression increase risk of extinction (Cook et al. 2006). This is particularly pertinent for endemic taxa (e.g., POW flying squirrel) that already exist in isolated populations by default, and for species that are less mobile (e.g., spruce grouse). The Conservation Strategy was designed to address this through the network of non-development LUDs, including the OGR system, and Forest-wide standards and guidelines both of which were intended to maintain habitat components important to a variety of species and maintain connectivity across the landscape. Alternative 5 would continue to do so by maintaining all elements of the current Forest Plan. By proposing less harvest and strengthening some of the existing standards and guidelines, Alternatives 6, 3, 2, and 1 in increasing order would have a greater chance of maintaining wildlife habitats and connectivity. However, because the Conservation Strategy is weakened under Alternatives 4 and 7, and these alternatives proposed the greatest amount of harvest and road construction, these alternatives would result in greater habitat loss, fragmentation and population isolation, and therefore have the greatest relative risk of not sustaining well distributed, viable wildlife populations across the Tongass over the long-term.

While this analysis is informative and updates the analysis of cumulative effects, it is important to note that the conclusions drawn by the wildlife viability panels done for the 1997 Forest Plan and brought forward for this Amendment fully considered the level of past and likely future harvest and associated development on non-NFS lands. Likelihood scores recognized the combined effects of harvest and road development on these land ownerships. Therefore, the viability ratings represent a cumulative effects prediction for each alternative. The goshawk, deer, marten, and marbled murrelet panels identified habitat loss as a key impact of the alternatives on these species. The old-growth reserve system was specifically identified as being important to the likelihood of maintainging viable, well-distributed populations of marbled murrelets, marten, and goshawks. Population isolation resulting from habitat fragmentation and barriers to migrating individuals in some biogeographic provinces was also identified as a key impact of the alternatives on endemic mammals. Effects associated with human access associated with road development were identified as key impacts to brown bears (in relation to DLP mortality and hunting pressure) and wolves (in relation to legal and illegal hunting and trapping).

Because wildlife populations exist across all land ownerships, managing adverse effects of management activities on wildlife often must be dealt with collaboratively. In addition, the population viability and distribution of wildlife on the Tongass is influenced in part by state and federal regulatory mechanisms such as harvest limits, season length, and population management objectives. Overall, the wildlife resources and associated habitat on the Tongass remain in good condition and are mostly dominated by old growth. As development continues through timber harvest, associated activities, and community expansion, particularly in areas where extensive development has already occurred (i.e., Prince of Wales Island) maintaining connectivity and roadless refugia will become increasingly important, particularly for wide-ranging species whose distribution depends on the availability of travel corridors and known "pinch-points" to access important habitats and move across the landscape. In addition, the management of human resources will continue to play a role in the viability and distribution of wildlife across the Forest.

While research since 1997 has provided a wealth of information on wildlife populations and habitat relationships in Southeast Alaska, there continue to be gaps in knowledge about the ecology and distribution of many species and direct correlations between land management activities and population impacts. The conservation strategy itself is a major step toward maintaining landscape connectivity on the Tongass, however, the effectiveness of its reserves and buffers in relation to their size, landscape pattern, and geographic distribution has yet to be scientifically tested (Powell et al. 1997). The future importance of individual elements of the conservation strategy in terms of their ability to support well-distributed and viable wildlife populations given potential cumulative effects of activities on forest system and non-forest system lands will depend on the direction of future managment activities (i.e., whether road construction will be prohibited in currently roadless areas, whether timber harvest will occur in pristine watersheds, etc.; Hanley 2005). However, despite these uncertainties, the risks associated with implementation of the Forest Plan are very low. The life of this amendment is expected to be 10 to 15 years at most, at which time another review will be undertaken. The current levels of harvest and road construction are at a 5-decade low and even if timber sales are made available and the timber industry responds very rapidly, there will be a period of preparation and transition prior to reaching the maximum harvest level allowed by the ASQ, particularly if one of the higher ASQ alternatives is selected.. Therefore, it is estimated that old-growth harvest levels are likely to be well below the maximum values evaluated in this EIS.

The effects of climate change may also contribute to cumulative effects. Warmer temperatures and decreased precipitation are anticipated to result in changes to vegetation and thus, the suitability of wildlife habitat, among other impacts (see *Climate and Air* section). Although many species may benefit (e.g., greater overwinter survival of deer, and thus a greater prey base for wolves, resulting from warmer winter termperatures during normal years), habitat changes resulting from a longer growing season, wind, fires, insect infestations, and disease may have variable effects on others. For example, Juday et al. (1998) concluded that the dramatic increase in gale force winds in coastal Alaska since the 1970s suggests that the risk of windthrow will be much greater in the future.

The greatest concerns for wildlife populations in relation to climate change, however, are the weather extremes that can be expected to occur periodically (Bermann et al. 1998). Periodic severe winter snowfalls, which may seem counterintuitive given the general warming trend, are anticipated (Juday et al. 1998). These stochastic events would be of greatest concern for populations that are limited in number or distribution. The predator-prey dynamic of wolves and deer provide an example of one system where these effects may be realized. Preliminary modeling has shown that during periodic severe winters reduced deer habitat capability due to snowfall would result in a disproportionately greater decline in the deer population (Person 2001). This could have repercussions on the wolf population, whose trends in size and volatility are sensitive to the available habitat capability for deer. At this time, no models exist that can be used in Forest Planning to accurately predict these effects. Some authors have noted though that the most effective means for managing for climate change impacts is through the development of ecosystem resistence which can be accomplished by maintaining a reserve system where active management is minimized (WWF 2003, Noss 2001). Thus the Forest Plan, with the reserve system through the conservation strategy represents a valid method to maintain a resilent ecosystem in the face of uncertain, future change.

Human Uses and Land Management

Lands

Affected Environment

This section addresses land ownership administration and adjustments and special uses of Tongass National Forest System (NFS) lands. Transportation and utility systems and land uses related to minerals are discussed in separate sections. Adjustment of land ownership within the Tongass boundaries can occur through Congressionally mandated conveyances, exchanges, and acquisitions, or through Forest Service administrative activities. Authorized special uses on the Tongass include industrial or commercial uses, such as commercial fishing camps, transportation facilities, electronic and other communications sites, and a variety of recreational uses. The *Recreation* section of the EIS discusses the recreation special uses; non-recreation special uses are discussed below. (Appendix E to the Forest Plan lists the approved communications sites on the Tongass.)

The exterior boundary of the Tongass National Forest established by Congress includes lands that had been conveyed to other ownership both prior and subsequent to creation of the Forest. Table 3.11-1 indicates the distribution of acreage by ownership type within the exterior boundary. Of the approximately 17,867,000 total acres (based on GIS analysis), nearly 16,774,000 acres (nearly 94 percent of the total) are federal lands administered by the Forest Service (this total includes lakes surrounded by NFS lands). The State of Alaska accounts for the largest non-federal ownership, with about 286,000 acres or almost 2 percent of the total (this figure does not include lakes surrounded by NFS lands). The Alaska Native regional corporation (Sealaska) accounts for approximately 293,000 acres, and 12 village corporations collectively own another 287,000 acres. The remaining acreage consists of lands owned by units of local government (cities and boroughs), private lands, and miscellaneous ownerships.

Table 3.11-1
Land Ownership Distribution, Tongass National Forest[1]

Ownership Type	Acres	Percent of Total
Federal/Forest Service administered[2]	16,774,000	93.9
State of Alaska[3]	286,000	1.6
Local Governments	44,000	0.2
Native Regional Corporation (Sealaska)	293,000	1.6
Native Village Corporations	287,000	1.6
Private Owners and Unknown	183,000	1.0
Total	**17,867,000**	**100**

Land Ownership Administration and Adjustment

A number of land adjustments have occurred on the Tongass since the adoption of the 1997 Forest Plan. Some lands have been conveyed from federal to other ownership, and these adjustments need to be documented on the Forest Plan maps. New lands that have become NFS lands during this period have not been formally given LUD designations. Specific designations need to be updated in a Forest Plan amendment.

From 1998 through August 2006, 50,277 acres of Tongass National Forest lands were conveyed to other entities. Most of these land adjustments were conveyances to the State of Alaska and Native corporations as authorized by the Statehood Act and the Alaska Native Claims Settlement Act of 1971 (ANCSA), and conveyances of Alaska Native Allotments as authorized by the 1906 Alaska Native Allotment Act. This acreage figure also includes parcels conveyed through land exchanges, a Small Tracts Act sale, and the disposal of two lighthouse reserves. Through land exchanges, purchases, and donations, the United States acquired 5,864 acres of new lands for inclusion within the Tongass during the same period. The balance of conveyances and acquisitions represents a net decrease of 44,413 acres of federal ownership.

Legislated Alaska Conveyances

Land ownership status within the Tongass is complicated by several ongoing Alaska land conveyances created under various federal legislation (USDA Forest Service 2003b). The Alaska Native Allotment Act of 1906 provided for Native individuals who had occupied lands prior to their designation as national forest to apply for conveyance of up to 160 acres, under conditions prescribed by the Act and federal regulations. As of August 2006, approximately 4,500 acres in 44 Native allotments had been conveyed, with an additional 3,500 acres pending adjudication by the Bureau of Land Management (BLM).

The 1958 Alaska Statehood Act authorized the State of Alaska to select 400,000 acres of vacant and unappropriated land from within the Tongass and Chugach National Forests in Alaska, to further the development and expansion of Alaskan communities. To date, under this provision of the Statehood Act, the state has received title to approximately 258,600 acres located in the Tongass National Forest. Approximately 37,400 acres remain to be conveyed to the state from the Chugach and Tongass National Forests.

ANCSA established processes for transfer of federal land to Alaska Native village corporations and regional corporations, and to Native individuals. ANCSA provided for the conveyance of 23,040 acres of surface estate lands (a full township, 36 square miles) to each of the 10 Native village corporations and 2 urban corporations located in Southeast Alaska. ANCSA provided that the subsurface estate under the village and urban corporation land would be conveyed to the Native regional corporation. ANCSA also included other provisions addressing land conveyances to Native regional corporations. Under Section 12c of ANCSA, 11 regional corporations were to share in the selection of 16 million acres. Section 14(h)(8) set aside a pool of 2 million acres to be transferred to the Native regional corporations in the state after certain other conveyances are completed. After the specified conveyances have been implemented, the remaining land in the pool will be divided among the regional corporations based on population, with approximately 22 percent of the balance going to Sealaska Corporation, the regional corporation for Southeast Alaska. Finally, ANCSA provided for selection and transfer of up to 160 acres to Native individuals who had occupied that land as a primary place of residence on August 31, 1971.

To date, approximately 571,000 acres within the Tongass have been conveyed under ANCSA. Each of the 10 Native village corporations and 2 urban corporations in Southeast Alaska has selected its authorized acreage; virtually all of that land has been conveyed, amounting to a total of approximately 279,000 acres. Approximately 292,000 acres have been conveyed to date to Sealaska Corporation, in addition to the subsurface estate under the lands owned by the village and urban corporations. Sealaska has selected about 171,000 additional acres. It is expected that approximately 64,000 acres of these lands will be conveyed to Sealaska.

Potential Future Conveyances

The major land conveyances described above have been authorized by Acts of Congress and implemented through additional legislation and regulations. In recent years there have been a number of other formal and informal proposals that, if authorized, might result in the transfer of Tongass NFS lands out of federal ownership. Several of these conveyance proposals are summarized below (see Appendix C for more detailed information):

- **Southeast Alaska Native Land Entitlement Finalization Act.** This bill was introduced in Congress in late 2007 as H.R. 3560, and is to provide for the completion of certain land selections by Sealaska under ANCSA and for other reasons. This legislative proposal represents the evolution of a Sealaska proposed land exchange (discussed below under Land Exchanges); however, the bill, as introduced, more closely resembles a conveyance rather than a land exchange. The bill allows Sealaska to select its remaining entitlement from areas outside the ten Southeast Alaska village withdrawal areas. It authorizes Sealaska to select and receive conveyance of its remaining land entitlement from three categories including economic development lands; sites with sacred, cultural, traditional, or historic significance; and Native enterprise sites.

- **University of Alaska Lands Bill.** Under the terms of Senate Bill 293, introduced in Congress on February 3, 2005, the University of Alaska would be allowed to select up to an additional 250,000 acres of federal land that would be managed to provide income for the university system. If enacted, the university would not be allowed to select lands within a federal conservation system area (e.g., a national park or a wilderness area) or Tongass NFS lands other than those within development Land Use Designations (LUDs), and the selections would be limited to areas of second-growth timber where timber harvest occurred after January 1, 1952.

- **Unrecognized Southeast Alaska Native Communities Recognition and Compensation Act.** Senate Bill 1746, introduced on June 29, 2007, proposes to allow Alaska Native residents of Haines, Ketchikan, Petersburg, Tenakee Springs, and Wrangell to organize as five Urban Corporations and to each receive 23,040 acres of surface estate lands and other compensation. (Sealaska Corporation would receive the subsurface estate to these lands.) These five communities were not included among the villages authorized to form corporations and receive land entitlements in 1971 under ANCSA, presumably because they did not meet the eligibility requirements. The language in Senate Bill 1746 does not identify the specific areas that would be available for selection and/or conveyance.

- **Alaska Natives Veterans Land Allotment Equity Act.** Introduced on August 2, 2007, as House Bill 3350, this proposes to redress certain obstacles created by the 1998 Alaska Native Veterans Allotment Act (Public Law 105-276). That Act amended ANCSA to provide Alaska Native veterans another opportunity to apply for a Native allotment of up to 160 acres of land under the repealed Native Allotment Act of 1906 (discussed above). This Act intended to compensate for the fact that Natives serving in Vietnam may not have been able to apply for their allotments prior to closure of the allotment program. The 1998 legislation contained several provisions regarding federal land status, prior use of the claimed land, and eligible military service dates that may be viewed by some as barriers to Native veterans obtaining their allotments.

- **Alaska State Forest Proposal.** State officials or interests have at times advocated the establishment of an additional Alaska State Forest to be managed to provide income for state government programs. One concept for such a management unit was for a 2-million-acre area on or near Prince of Wales Island, which would require transfer of extensive areas of current Tongass NFS lands to the State. To date, no federal legislation to implement such a proposal has been introduced in Congress.

Land Disposal

Federal agencies responsible for administering public lands sometimes dispose of lands to other governments or private parties. Such disposals typically involve relatively small land parcels that have been determined to be "surplus" or "excess" property under federal property regulations.

With respect to the Tongass, one example of land disposal involves the conveyance of historic lighthouse or light station properties in Southeast Alaska that have been managed jointly by the U.S. Coast Guard and the Forest Service. The National Historic Lighthouse Preservation Act of 2000 authorizes the General Services Administration (GSA) to dispose of historic light stations to "eligible entities" that are required to make the light stations available to the general public for education, park, recreation, cultural, or historic preservation purposes (USDA Forest Service 2005c). The Forest Service has been working with GSA to dispose of light stations while granting Forest Service easements to the recipients for occupancy of the underlying NFS lands. Two light stations have been disposed of under this program; four other stations have been identified as candidates for disposal. Most of these stations have small land reserves associated with them, although the Forest Service is working with the Coast Guard and BLM to reduce the acreage of larger reserves associated with some stations.

Land Exchanges

Administrative land exchanges, in which NFS lands can be conveyed to another entity in exchange for lands of equal value, are another form of land ownership adjustment. Complex land exchanges are sometimes authorized by Congress through special legislation. In addition to the Alaska conveyances discussed above, the Forest Service has completed several land exchanges involving Tongass NFS lands. These adjustments are summarized below:

- Under the Kake Tribal Corporation Land Transfer Act (Public Law 106-283), approved by Congress on October 6, 2000, the Forest Service was directed to convey 1,389 acres of Tongass NFS lands (which had previously been selected by the State of Alaska) in the Jenny Creek area near Kake to the Kake Tribal Corporation. This Act also provided for transfer of 1,430 acres of land owned by the Kake Tribal Corporation and Sealaska to the City of Kake an exchange of the subsurface estate (mineral rights) for two areas (each of over 1,100 acres) between the Forest Service and Sealaska. The Act, technically an amendment to ANCSA, was enacted to provide protection and management of the Kake municipal watershed.
- Under the Hood Bay Land Exchange, the Forest Service received a 54-acre parcel that had formerly been a private inholding within Admiralty Island National Monument and the Kootznoowoo Wilderness (USDA Forest Service 2006c). The United States conveyed and relinquished all reversionary interests on 144 acres of land at Sitka to the Alaska Pulp Corporation.
- Through an exchange with the Kennecott Greens Creek Mining Company, Inc., the Forest Service received one 50-acre parcel within the Misty Fiords National Monument Wilderness and two parcels totaling approximately 139 acres within Admiralty Island National Monument Kootznoowoo Wilderness (USDA Forest Service 2006c). The United States conveyed the subsurface mineral estate on 7,301 acres at Hawk Inlet/Young Bay on Admiralty Island.

There have also been discussions regarding potential future land exchanges between the Forest Service, a number of Native corporations, and other entities that could adjust land ownership on the Tongass.

In late 2007, Shee Atika, Incorporated (an Alaska Native Village Corporation) approached the Forest Service about a possible exchange of NFS lands on West and North Yakobi Island and on western Chichagof Island, for Shee Atika surface estate located at Cube Cove. Both parties are discussing the concept and neither party has made any binding commitments on proceeding further.

Also in late 2007, the Trust Land Office (State of Alaska, Department of Natural Resources) representing the Mental Health Trust Authority, presented a conceptual proposal to the Forest Service to exchange approximately 20,000 acres of lands managed by the Trust Land Office in Southeast Alaska for an equal value of Tongass National Forest lands on Prince of Wales Island. The parcels the Trust has offered for exchange are mostly adjacent to NFS lands and are also adjacent to, or in the immediate vicinities of, Skagway, Juneau, Petersburg, Wrangell, Sitka, and Ketchikan. At this point, the Forest Service is considering the concepts of the proposal and has made no agreements on whether or not it will pursue this exchange further.

The potential exchange that has received the most attention and discussion is known as the Sealaska Proposed Comprehensive Tongass-wide Land Exchange (USDA Forest Service 2005d). In August 2002, Sealaska Corporation submitted a proposal to the Forest Service to exchange approximately 100,000 acres of NFS lands for Sealaska Corporation lands and selection rights under ANCSA. The Tongass-wide exchange proposed by Sealaska involves lands throughout Southeast Alaska. The goals of the exchange are to consolidate NFS lands and Sealaska lands, and to finalize Sealaska's remaining land selections under ANCSA. This proposal has recently evolved into the Southeast Alaska Native Land Entitlement Finalization Act which has been introduced in Congress (see above under Potential Future Conveyances).

At present, about 171,000 acres in the ANCSA withdrawal areas are encumbered by Sealaska selections. Other lands within these areas have not been selected by a Native corporation but will remain withdrawn until the ANCSA conveyances are completed.

Based on current information from BLM, Sealaska has approximately 64,000 acres of lands yet to be conveyed. This includes approximately 20,000 acres of unconveyed ANCSA entitlement under Section 14(h)(8), in addition to approximately 44,000 acres of 14(h)(8) lands resulting from the 2004 Alaska Land Transfer Acceleration Act, P.L. 108-452.

The proposed land exchange would enable Sealaska to acquire other lands outside of the ANCSA withdrawal areas, in addition to the Native heritage 14(h)(1) parcels. This is not authorized under ANCSA except by exchange. Land exchanges are discretionary, voluntary real estate transactions between federal and non-federal parties. At present, there is no binding land exchange agreement in place signed by the Forest Service and Sealaska that would enable Sealaska to receive lands outside of the withdrawal areas.

The Forest Service completed a draft feasibility report on the exchange proposal in 2003. After lengthy discussions and several modifications to the proposal, in 2005 the Forest Supervisor informed Sealaska that the Forest Service was not willing to move forward with the exchange because of a lack of substantial agreement on the parcels to be exchanged, concerns over a variety of resource issues, and the need for a revision to the Forest Plan to accommodate the exchange due to the magnitude of the resulting changes in LUDs.

Land Acquisition

Land ownership adjustments can also occur through the outright purchase of lands or the acceptance of land donations for inclusion in the Forest. Purchases typically involve small inholdings, always involve a willing seller, and usually involve parcels surrounded by designated wilderness or other sensitive resource lands. Since 1997, the Forest Service has acquired 17 parcels totaling approximately 5,864 acres of land in various locations within the Forest (USDA Forest Service 2006c). These figures include the parcels obtained through the Hood Bay and Greens Creek exchanges discussed above; apart from these exchanges, the acquisitions total 12 parcels and 5,621 acres. The largest acquisition involved two parcels and 2,939 acres near Petersburg Creek and 1,045 acres at Mt. Verstovia near Sitka. Other purchases included an Unuk River parcel in the Misty Fiords National Monument Wilderness and parcels at Favorite Bay and Hood Bay in the Admiralty Island National Monument/Kootznoowoo Wilderness. Donations included a parcel at Cape Bingham and two at Bohemia Basin, including portions in the West Chichagof-Yakobi Wilderness in both locations, and a parcel at Windham Bay in the Chuck River Wilderness.

The Forest Service obtained the Petersburg Creek and Verstovia parcels through a legislated program with the State of Alaska Mental Health Land Trust, which has as its mission to generate revenue to support mental health services in Alaska.

Congress directed the Forest Service to purchase lands from the Trust and allocated funds for the purchases. The Forest Service is currently working on an acquisition in the Deer Mountain area near Ketchikan, which will be the last component of this program.

Congress has directed the Forest Service to make a similar purchase under the Craig Recreation Land Purchase Act (PL 108-325), passed in October 2004. The Act provides for the Forest Service to acquire the surface rights to approximately 350 acres surrounding and near the Sunnahae Trail from the City of Craig (USDA Forest Service 2005e). The city would use the funds received under this acquisition to purchase 10 acres of property within Craig for harbor expansion, development, and other purposes. Congress has not yet appropriated funds for the purchase of the Sunnahae Trail lands.

Withdrawals/Encumbered Areas

Withdrawals and encumbrances are other key aspects of land ownership administration. Withdrawal is the withholding of an area of federal land from settlement, sale, mineral location, or entry under some or all of the general land laws for the purpose of limiting activities under those laws in order to maintain public values in the area. In general, an encumbrance is a claim, lien, charge, or liability attached to and binding real property (Black 1979, as cited in USDA Forest Service 2003b). In the context of the Tongass, an encumbrance is a land claim of some type that removes NFS lands from the full range of Forest Service administrative functions.

By acreage, the largest withdrawal action applies to the more than 5.7 million acres in designated wilderness areas, which are withdrawn from entry under the mining laws. Many of the administrative withdrawals date back several decades and include withdrawals around lighthouse and light station sites, and a large number of power site withdrawals intended to preserve options for hydroelectric development at promising sites.

The land conveyance processes established by ANCSA delineated areas of federal lands within which Native village corporation land selections were to be located. These areas, totaling an estimated 1.8 million acres (including large areas of saltwater) on the Tongass, were withdrawn and will likely remain encumbered in the land status records until all lands to which the Native corporations are entitled have been conveyed. Other areas of the Forest have not been formally withdrawn, but are similarly encumbered as a result of land selections. For example, while the Alaska Statehood Act did not withdraw specific federal land areas identified for land selection by the state, those lands that have been selected by the state but not yet conveyed are nevertheless encumbered. Likewise, Native allotments that have been claimed but not conveyed and a number of small-scale Sealaska selections under ANCSA Section 14 (h)(1) are outside of the ANCSA withdrawal areas and are encumbered. Altogether, approximately 395,000 acres of Tongass NFS lands are encumbered by such transitional ownership situations (USDA Forest Service 2006e).

Special Use Authorizations

Uses of NFS lands by entities other than the Forest Service can be authorized under a special use permit, subject to applicable regulations found in 36 CFR 251. Generally, most permits are issued for periods of 5 years or less. Complex permits for long-term uses such as hydroelectric facilities may be issued for periods of up to 50 years. As of August 2006, there were 715 special use permits currently issued on the Tongass. The number of permits on the Tongass at any given time may fluctuate between 700 and 750. Nearly half of the permits issued on the Tongass are related to outfitter and guiding and other recreational uses of NFS lands. The remainder involve a wide variety of uses including, but not limited to, communications sites, roads, cabins, organization sites, hydroelectric projects, temporary facilities, aquatic farming activities, military training, sanitary landfills, and fish camps.

Communication and Other Electronic Sites

A communication or other electronic site is a dedicated land use allocation of NFS land. These sites are used for electronic communication systems, including electronic transmitters, receivers, and passive microwave reflectors. These uses of federal land are authorized by the Federal Land Policy and Management Act of 1976 and the Telecommunications Act of 1996. As of August 2006, there were 69 designated electronic sites throughout the Tongass (see Appendix E to both the 1997 Tongass Land and Resources Management Plan and the proposed Forest Plan Amendment). Fifty-two (52) of these sites were occupied under special use permits by non-Forest Service parties, while the remaining sites are for Forest Service facilities. A few of the sites have several special uses authorized. The majority of sites are limited to one user. All sites are currently open to more than one user if the need arises. Some of the sites are operated by the Coast Guard, the Federal Aviation Administration, the National Weather Service, and a variety of other private and public entities. Applicants for new communications uses will be encouraged to co-locate their facilities at existing, approved sites.

Recreation-Related Permits

As of August 2006, the Forest Service administers 390 special use permits for purposes related to recreation. These included 275 outfitter/guide permits, 65 isolated cabins, and 15 recreation residences. Isolated cabins and recreation residences, although similar in many ways, are managed differently because of the different authorities used to grant use and occupancy. Construction of new cabins is regulated by Alaska National Interest Lands Conservation Act of 1980 (ANILCA) and generally prohibited, except under limited circumstances. Existing cabins are expected to decrease in number over time as a result of ANILCA direction limiting the transfer of permits.

Camps and Cabins

Two organization camps operated on the Tongass under special use permit in 2005. Based on prior authorizations, the Forest Service also administered 15 permits for summer homes or recreational cabins. Construction of new cabins is prohibited except under quite limited circumstances, and the existing cabins are expected to decrease in number over time as a result of restrictions on transfer of the permits.

Roads and Rights-of-Way

Inholders and other landowners are allowed reasonable access across NFS lands to use their own lands under provisions of ANILCA and other federal laws. Easements are also issued to the Alaska State Department of Transportation for state-managed highways. The Forest Service administered 39 easements or right-of-way permits in 2006. The types of authorizations include 1 railroad right of way, 1 Department of Transportation easement, 13 Forest Road and Trail Act easements, 4 Federal Land Policy and Management Act easements, and 20 Federal Land Policy and Management Act rights-of-way.

Other Special Uses

Non-recreation special use authorizations accounted for 325 permits in August 2006. Types of uses in this group included hydroelectric projects, mariculture- and agriculture-related activities, uses for schools and municipalities, weather monitoring, filming and photography, and power lines.

Hydroelectric Projects*.* There are 11 existing hydropower projects on the Tongass that are operated under license from the Federal Energy Regulatory Commission (FERC). Of the 11, 8 are also under special use permit from the Forest Service and authorized under the Federal Land Policy and Management Act. As of August 2006, there were an additional 11 proposed projects that are in various stages of the FERC licensing process.

The Forest Service is currently conducting environmental review under the National Environmental Policy Act (NEPA) for the proposed Angoon hydroelectric project, located approximately 6 miles north of the City of Angoon on Admiralty Island. Kootznoowoo, Incorporated, the Native village corporation for Angoon, proposes to develop a 1 megawatt hydro project on Thayer Creek to supply electricity for Angoon. The project is authorized under ANILCA Section 506(a)3(B), subject to conditions imposed by the Forest Service, and is not subject to the Wilderness Act of 1964. FERC has determined that it does not have jurisdiction over the project because Admiralty Island is a Congressionally designated National Monument on NFS lands. Therefore, FERC is not involved in project review. As directed by ANILCA, the Forest Service will issue special use permits, with specified conditions, to allow construction and operation of the project when the environmental analysis is complete and all NEPA requirements are met.

Other Energy Resources. The Tongass has recently received some interest from energy companies exploring for oil and gas and geothermal resources (see related discussion in the *Minerals* section of this chapter). These exploration activities require a special use permit when they occur on NFS lands.

Environmental Consequences

Direct and Indirect Effects

No significant environmental consequences within the Lands category are anticipated for any of the alternatives. The NFS land base is the same for all seven alternatives, at just under 16.8 million acres. An adjustment to the suitable timber land base has been made for each alternative for lands anticipated to be conveyed in the future ("encumbered"). Minor changes to the land base may continue to occur as a result of the ongoing conveyance processes, or from future land exchange, disposal, and acquisition actions. Any such changes that would occur are irrespective of the goals associated with any alternative, as none of the alternatives incorporate any specific land adjustment that is unique to the alternative.

The Forest Service would continue land administration activities under the respective Forest-wide standards and guidelines presented in Chapter 4 of the Forest Plan. Those standards and guidelines reflect minimal changes from the current Forest Plan direction. The only substantive change in the standards and guidelines is the additional statement that motorized access may be authorized as part of a special use authorization, subject to the provisions of 36 CFR 212, 251 and 261. In other respects, administration of special use permits would continue as at present under all alternatives. The number of communication and other electronic sites on NFS lands under special use permit has increased somewhat in recent years, and additional sites may be permitted in the future. Permits for camps and cabins may decrease somewhat over time because of restrictions on new uses of this type. Based on recent trends, minor future increases in special use permits for other recreation purposes, rights-of-way, and other special uses are possible.

Additional special use permits may be granted in the future; the environmental impacts of those actions would be evaluated through the permit approval process. The Forest Service would issue permit conditions to address the impacts of new permits and renewed permits. Special use permits generally apply to small, specific areas and activities that have limited impacts. Impacts from permitted activities can not be predicted at this time, would not vary among the alternatives, and are not likely to be significant. The future addition of electronic sites by private industry could help improve electronic signal coverage Forest-wide.

Cumulative Effects

Forest Service land administration activities under the updated Forest Plan are not considered to have the potential to create or contribute to significant cumulative effects. To the extent that special use permits increase in number and affected acreage, environmental effects from future permits would add to those of permits already in effect. As noted above, however, those effects are not likely to be significant. In general, land ownership adjustments executed by the Forest Service are made in response to direction from others, primarily Congress through legislated land conveyances or exchanges. No land ownership adjustments are proposed under any of the Forest Plan alternatives, and none of the potential adjustments discussed above and in Appendix C is considered reasonably foreseeable. To the extent that any of the potential conveyance or exchange proposals were adopted in the future, they would have a cumulative effect on the NFS land base within the Tongass. There has been a substantial transfer of federal lands in Southeast Alaska to other ownership since statehood.

Transportation and Utilities

Affected Environment

There are three principal types of travel in Southeast Alaska: air, water, and ground. Historically, marine transportation has been the major method of moving freight and passengers; however, during the last five decades, air services have developed to serve the growing demand for rapid transportation between communities within Alaska and to the contiguous United States. Residents of the region are dependent on air and water transportation for travel between most communities, rather than roads or rail. A roaded transportation system has developed on National Forest System (NFS) lands, largely in support of timber harvesting.

Only three cities in Southeast Alaska are connected to the continental road system: Haines, Skagway, and Hyder. Several cities in Southeast Alaska are linked to Bellingham, Washington via the Alaska Marine Highway. Ketchikan is also linked by ferry to the Canadian community of Prince Rupert, British Columbia. In addition, several ferries connect communities on a weekly or twice-weekly basis. Prince of Wales Island has the only road system in Southeast Alaska that interconnects island communities. Several possibilities exist for state highways that could connect some communities of Southeast Alaska to the continental road system. Several new internal corridors are also possible.

The Alaska Department of Transportation and Public Facilities (DOT&PF) issued the Southeast Alaska Transportation Plan (SATP) in August 2004 (Alaska DOT&PF 2004). The SATP requested 34 essential transportation and utility corridors be reserved and incorporated into the Tongass Land and Resource Management Plan. Most corridors are planned for infrastructure construction by Alaska DOT&PF. For other corridors, Alaska DOT&PF has requested the Forest Service improve and connect forest roads. The SATP proposes doubling the forest highway system, which would result in a 1,032-mile system.

Historically, Southeast Alaska has relied on a “marine highway system” to augment its limited roads and highways. The Marine Highway System primarily consisted of long line ferries, which are becoming obsolete with current Coast Guard regulations, and are increasingly costly to operate. The SATP calls for transitioning away from the long line ferries to a system of expanded roads and shuttle ferries. Strategically, the plan calls for centering transportation and access around three major highway linkages: the Juneau Access Road (which would link Juneau to the continental road system via Skagway), a Sitka highway (which would link Sitka with the east side of Baranof Island), and a mid-region connector to the Cassier Highway in British Columbia, Canada (the Bradfield Canal Corridor is one alternative under consideration).

Public Law 109-59, the Safe Accountable Flexible Efficient Transportation Equity Act: A Legacy for Users, was passed in August 2005. It refers to Map 92337, which shows marine access points, log transfer facilities (LTFs), and proposed transportation corridors in Southeast Alaska. This map shows 22 corridors, all but one of which is also in the SATP (the Whale Pass to Exchange Cove corridor on Prince of Wales Island is not included in the SATP).

Because the Southeast Region of Alaska DOT&PF lies largely within the Tongass National Forest's boundaries, many of the proposed road projects would cross NFS lands and require Forest Service coordination and U.S. Department of Transportation easements. The proposed major linkages for the Juneau Access, a Sitka Highway System, and the Cassier Highway connection would each cross Tongass National Forest land. The completion of the SATP has initiated more site-specific planning, and has focused on a request for a change in land use designation (LUD) in the Forest Plan.

The Forest Service signed a Memorandum of Understanding with the State of Alaska in 2006 to provide rights-of-way for the road corridors covered by Public Law 109-59. These corridors are displayed on the alternative maps. The Memorandum of Understanding also grants easements to the Forest Service for marine access points and LTFs listed on Map 92337. To date, eight rights-of-way have been granted to the State, and work is proceeding on the remaining right-of-way grants. The Federal Highway Administration issued a Record of Decision (ROD) in 2006 approving a road on the east side of Lynn Canal from the current terminus of State Highway 7 to the Katzehin River. From there, shuttle ferries would continue to Haines and Skagway. Site-specific planning is also underway for the Sitka Access and the Northern Panhandle Transportation Study. The Forest Service continues to be involved as a cooperating agency with Alaska DOT&PF for all highway National Environmental Protection Agency (NEPA) efforts, identifying the impacts to the Tongass National Forest, and creating opportunities for appropriate mitigation and recreational enhancements. This analysis considers the request for reserving these transportation corridors (refer to the alternative descriptions in Chapter 2).

In addition to the corridor reservation request, the SATP identifies the Forest Service as a "transportation partner" highlighting that there are 3,600 miles of Forest Service roads on the Tongass National Forest that many communities rely on. The SATP also calls out the merits of the Forest Service's role as a public roading agency, recognizing the need for lower standard public road links to Southeast Alaska's smaller communities.

The SATP is based on two fundamental concepts: 1) an integrated multi-modal transportation system (a combination of road segments linked to shuttle and mainline ferry services within key corridors), and 2) a combination of sub-area or zone and regional transportation services and facilities. The four identified major travel corridors or zones are: 1) Juneau-Haines-Skagway, 2) Juneau-Sitka-Petersburg, 3) Petersburg-Ketchikan, and 4) Ketchikan-Prince Rupert, British Columbia. New ferry terminals have been completed at Mitkof Island and Coffman Cove. The Inter-Island Ferry Authority, which operates a route between Hollis and Ketchikan, also operates the new route serving Wrangell, Coffman Cove, and Mitkof Island.

A number of different groups have identified several corridors for consideration as major transportation routes. The SATP identifies several potential extensions of the Inside Passage Highway among its long-term actions. Several possibilities are under consideration, including extensions or new highway construction on Kupreanof Island (to connect Kake and Petersburg), Cleveland Peninsula, and Revillagigedo Island (including an extension of the Revilla road to Shelter Cove, and a road from Carroll Inlet to Shrimp Bay). The SATP recommends reserving these possible future alignments as highway corridors. The SATP also proposes a study to consider the viability of constructing a road to connect Sitka with the east side of Baranof Island, either at Rodman Bay or Warm Springs Bay.

Other potential routes that have been discussed in recent years include a route along the west shore of Lynn Canal, two Juneau-to-Canada routes along Taku Inlet, the East Bradfield River corridor connection to the Cassiar Highway, several other road corridors near Wrangell, a coastal alignment connecting Thorne Bay and Coffman Cove, a road connecting North Whale Pass and the East Prince of Wales road, and a road to the southeastern tip of the Kasaan Peninsula. In addition to the routes listed above, draft Transportation System Concept maps prepared for the Southeast Conference identify a potential route connecting Hoonah and Tenakee Springs, and a short connector route between the Chatham and Corner Bay road systems. The Southeast Conference maps also identify an alternative corridor between Kake and Petersburg via a ferry across Duncan Canal.

When a National Forest Transportation System road (discussed in the next subsection) provides a connection between communities, serves local needs such as mail delivery, or connects public roads within the Tongass National Forest, it can be designated as a forest highway (see 23 U.S.C. 101 for technical definition). Forest highways are usually upgraded to state highway standards, during which jurisdiction passes to the State. To date, the Alaska DOT&PF, Federal Highway Administration, and Forest Service have agreed to designate a potential 362 miles as forest highways; the State would assume jurisdiction and maintenance responsibility for 181 miles of these highways.

Other transportation facilities within Southeast Alaska include more than 300 marine facilities (docks, small boat harbors, refuge floats, and boat launch ramps), 12 major airports, approximately 35 seaplane bases or floats, and numerous heliports and airstrips (Alaska DOT&PF 2004).

National Forest Transportation System Roads

National Forest Transportation System roads are constructed to provide access to NFS lands and are included in the Forest Development Transportation Plan (see Transportation Standards and Guidelines in Chapter 4 of the Forest Plan [USDA Forest Service 1997b]). They are considered NFS roads, as are other roads that are wholly or partially on NFS lands and are intended to be maintained for the long term (see text box on Road Types). They are functionally classified as arterial (serving large land areas and usually connecting to public highways), collector (serving smaller areas, usually connecting to arterials or public highways), and local (terminal roads, may connect to any other type).

NFS roads are also managed by a system of maintenance levels, depending on their intended use and suitability for various types of vehicles. These levels range between level 1 (closed), level 2 (suitable for high-clearance vehicles), level 3 (suitable for passenger vehicles, rough surface), level 4 (suitable for passenger vehicles, smooth surface), and level 5 (suitable for passenger cars, dust free, possibly paved). Maintenance can include reconditioning the original road template, grading the road surface, cleaning roadside ditches, and removing vegetation that may encroach upon the road or block vision. Grading and other maintenance would generally take place more often on a maintenance level 4 road than on a level 3 road, and would be expected to occur less often on a level 2 road. Level 1 roads are left to a self-maintaining condition that requires little or no maintenance.

With the exception of a few administrative sites and campgrounds, most forest roads are single lane, constructed with blasted quarry rock, and designed for off-highway loads. Typical collector and local roads are 14 feet wide with a rough gravel surface. Higher standard arterial roads are normally 16 feet wide, may have a smooth gravel surface, and are designed for speeds of up to 30 miles per hour. Travel speed on lower standard roads is often controlled more by surface roughness than by horizontal alignment or road gradient.

For the Tongass, the demand for roads has primarily been a function of the demand for access to timber resources. The maintenance and reconstruction requirements of the existing system depend mainly on the volume of timber hauled and, to a lesser extent, on recreational use. The amount of future construction is anticipated to continue to be largely determined by the need to access timber resources.

Road Types

National Forest System roads: Roads wholly or partially within National Forest System (NFS) land that the Forest Service determines are needed for the protection, administration, and utilization for the NFS and the use and development of its resources.
Unauthorized roads: Roads that are not forest roads or are temporary roads not included in the forest transportation atlas.
Temporary roads: Roads that are not forest roads and are not listed on the forest road atlas, but are necessary for emergency operations or authorized by contract, permit, lease, or other written authorization.

Currently, there are approximately 3,532 miles of authorized roads on NFS lands, approximately 2,485 miles of which are not maintained for highway vehicles (maintenance level 1 and 2). There are another 607 miles of roads that are on non-NFS lands. In addition, there are about 1,409 miles of unauthorized roads—roads that are not maintained by the Forest Service. These roads provide access to about 8 percent of the Tongass National Forest. Over half of the roads suitable for highway vehicles are connected to communities. Between 1984 and 1993, an average of 168 miles of road was constructed annually. The 1997 Forest Plan estimated that 106 miles of road would be constructed annually in the first decade of the Plan. However, actual construction was well below that level, averaging less than 25 miles annually between 1997 and 2005. During that same time period, approximately 94 miles of road were decommissioned. The result was a net addition of 126 miles of road, compared to the 954 miles predicted for the first 9 years.

The steep, densely vegetated terrain of Southeast Alaska limits the use of typical off-highway vehicles (OHVs) such as three-wheelers and all-terrain vehicles to beaches, communities, road systems, braided river channels, and frozen or snow-covered areas. Most trails in Southeast Alaska do not lend themselves well to the use of such vehicles because of wet ground conditions that often necessitate the use of boardwalks. With the exception of a few specific areas, the Tongass has not experienced the kinds of resource damage typically associated with OHVs elsewhere. The Tongass contains many unauthorized roads, some utilize old roadbeds and some are user-created. Many of these unauthorized roads and trails are used by OHVs for recreation. It is anticipated that travel management plans scheduled for completion by December 2009 will decide which of these unauthorized roads are incorporated into the Forest transportation system and which will be closed as funding becomes available.

Prior to 2005, the Forest was designated open to OHVs except for Wilderness, National Monuments, and Research Natural Areas. Site-specific closures were considered in specific locations where conflicts with other uses, public safety problems, or damage to resources could occur. The goal of OHV management is to ensure resource protection and public safety, minimize user conflicts, and provide diverse opportunities for Forest users. A specific set of closures was consolidated in the Juneau area in November 1985 as the “Off-Road Vehicle Travel Plan” for the Juneau Ranger District. This travel plan was incorporated in the Forest Plan by reference. In November 2005, the Forest Service adopted a final rule for managing motor vehicle use, including OHV use, on national forests throughout the United States. Under this rule, the travel management plans will designate a system of roads and trails for OHV use, and identify if any areas for cross country travel are appropriate and do not cause resource damage. Use maps are scheduled to be completed by 2010.

In early 2001, the Forest Service adopted a new road management policy that requires the agency to maintain a safe, environmentally sound road network that is responsive to public needs and affordable to manage. The policy includes a science-based roads analysis process designed to help managers make better decisions on roads. The Forest completed a Forest-wide roads analysis for maintenance level 3, 4, and 5 roads in 2003. Ranger Districts are in the process of completing roads analysis on maintenance level 1 and 2 roads as well as unauthorized roads.

The transport of harvested timber from isolated islands in Southeast Alaska requires both land and water routes to reach processing facilities. LTFs are used to transfer logs to barges or rafts for towing. About 116 LTFs currently exist on the Tongass and there are 59 marine access points suitable for transferring logs to barges that have current permits on NFS lands. Another 10 marine access points no longer have permits. The Memorandum of Understanding discussed above grants the

Forest Service easements to use the 126 LTFs on state lands listed on Map 92337. In addition, 59 proposed LTF sites have been identified on NFS lands.

Power Transmission Lines

A number of power transmission lines link existing hydroelectric projects with the nearest larger community in Southeast Alaska. The State of Alaska has proposed corridors for transmission lines and/or undersea cables to link many Southeast Alaska communities to each other and to British Columbia. Several projects are either in the NEPA stage or under construction. The Swan Lake–Lake Tyee Intertie corridor runs from the Swan Lake Hydro project near the head of Carroll Inlet, north to the Tyee Hydro project at the head of Bradfield Canal. The route is shown as a potential power transmission corridor on the alternative maps. NEPA was completed in 1997 and construction began in 2002; most of the corridor has been cleared and approximately three-quarters of the power pole foundations have been built. The State Legislature approved $46.2 million for the project. As a result of the Swan Lake-Lake Tyee Intertie, another potential corridor, which runs down the Cleveland Peninsula connecting the Tyee power line with Ketchikan and Meyers Chuck, is not likely to be needed.

Construction of a transmission line connecting Ketchikan with Metlakatla via Saxman is expected to begin soon. The route is shown as a potential power transmission corridor on the alternative maps. This corridor is primarily on private land. It would run from Ketchikan to Saxman, then across the channel to Annette Island, and then southwest and south along the northern portion of the island to Metlakatla.

Kootznoowoo Inc., a Native village cooperative, has proposed developing a hydroelectric facility on Thayer Creek and a transmission line between the Thayer Creek facility and Angoon. The route is shown as a potential power transmission corridor on the alternative maps. This project is authorized by Congress and is currently being analyzed by the Forest Service in an EIS. The 1-megawatt, run-of-the-river hydroelectric project on Thayer Creek (north of Angoon) includes a 10-foot-high diversion dam, a diversion pond, 1.3 miles of pipeline and penstock, a powerhouse, and 6 miles of overhead transmission line (plus a marine segment) to carry the power south to Angoon. The DEIS was released in May 2007.

The Juneau to Hoonah Transmission Line route runs from Juneau across northern Douglas Island and underwater to the north end of Admiralty Island and then underwater again to approximately 10 miles east of Hoonah, where it transitions onto land and continues to Hoonah. NEPA has been completed and the line has been constructed to Hawk Inlet at the north end of Admiralty Island (the Juneau to Greens Creek portion of the transmission line). The route is shown as a potential power transmission corridor on the alternative maps.

The Kake to Petersburg Transmission Line would cross the Wrangell Narrows (going from Mitkof to Kupreanof Island) near the Tonka LTF and proceed west across Duncan Canal. It would follow existing logging roads for the majority of its length. The route is shown as a potential power transmission corridor on the alternative maps.

Other potential projects include power lines between Juneau and Skagway, Juneau and Hoonah (the Juneau to Greens Creek portion has been completed), Hoonah and Pelican, Hoonah and Tenakee Springs, Tenakee Springs and Angoon, Angoon and Sitka, Sitka and Kake, Thorne Bay and Ketchikan, and Klawock and Hydaburg. Also planned are power lines between the proposed Lake Dorothy, Otter Creek, and Sunrise Lake Hydroelectric Projects and existing power lines or communities. A power line from the Tyee hydropower site along a potential Bradfield Canal/Craig River road corridor route to Canada is also a potential route that has been considered.

Transportation and Utility Systems in the Forest Plan

The Forest Plan applies the Transportation and Utility Systems LUD to the potential rights-of-way corridors and associated uses for selected potential and existing transportation systems and utility corridors. These systems include state and federal highways, power lines of 66 kilovolt capacity or greater, and pipelines 10 inches or more in diameter, if they are a public utility. This LUD is intended to minimize potential conflicts, such as over-determining the appropriate visual quality objective, should development of any of these projects occur. With certain exceptions, transportation and utility systems are allowed throughout the Tongass as directed by Title XI of the Alaska National Interest Lands Conservation Act of 1980.

Environmental Consequences

Direct, Indirect, Effects

The following discussions address the direct, indirect, and cumulative effects of the alternatives on the transportation and utilities infrastructure of Southeast Alaska. Analyses examine both the existing system and all reasonably foreseeable changes.

Effects on the National Forest Transportation Road System

Table 3.12-1 displays the maximum anticipated road construction by alternative over the next 100 or more years. These numbers tend to overestimate total road miles because they include unauthorized roads, most of which are likely to be decommissioned during the next few decades. New road construction estimates are directly related to proposed timber harvesting activities; they are based on the maximum harvest levels projected for each alternative. These estimates are primarily based on the logging system and transportation analysis (LSTA) completed in 2007 for the majority of the mapped suitable lands on the Tongass under the alternatives (refer to the *Timber* section). Where suitable lands were not covered by the LSTA (primarily in portions of Alternatives 4 and 7), they were estimated using the ratio of road miles to suitable acres based on the LSTA by Value Comparison Unit.

Table 3.12-1
Estimated Maximum Road Construction and Cumulative Miles of National Forest System Roads by Alternative After Full Implementation (100+ years)[1]

Alternative	New Road Construction	Existing Roads [2]	Cumulative Roads [2]
1	774	4,941	5,715
2	2,079	4,941	7,020
3	2,799	4,941	7,740
4	4,890	4,941	9,831
5	3,874	4,941	8,815
6	3,744	4,941	8,685
7	5,825	4,941	10,766

[1] Estimates are based on the maximum harvest allowed under each alternative; therefore, they represent a maximum estimate. Numbers do not include decommissioning of roads.
[2] Includes unauthorized roads, most of which are likely to be decommissioned.

Roads have the potential to affect fish habitat, soils, and water quality by increasing erosion and landslide potential, changing recreation settings and opportunities, altering scenery, and increasing legal and illegal wildlife harvest. These types of effects are discussed in the subject resource sections of this chapter, as applicable.

Based on current practices, most new roads would be closed to motorized traffic once their initial use is over. These roads are built for silvicultural purposes under exemptions granted under Section 404(f)(1) of the Clean Water Act. The construction or maintenance of forest roads used for the sole purpose of silvicultural activities is exempt from regulation under Section 404 of the Clean Water Act. Roads that remain open for recreation or subsistence use do not qualify under this exemption (U.S. Army Corps of Engineers 2004); therefore, these roads should be closed following completion of silvicultural activities. The roads would either be decommissioned or placed in storage. Bridges and culverts may be removed (or culverts may be bypassed), erosion control measures would be applied as needed, and the roadbeds would be allowed to revegetate naturally.

In addition to normal maintenance that would accompany all alternatives, each alternative would result in reconstruction of a portion of the existing road system in each decade, primarily roads that have been placed in storage (maintenance level 1). Estimates range from 925 miles under Alternative 1 to 2,371 miles under Alternative 7 (Table 3.12-2). Reconstruction of a road maintains the original investment and makes the road suitable and safe for intended use. Reconstruction involves the rehabilitation of the original roadbed, and can include cleaning ditches, replacing drainage structures, re-installing bridges, and grading and shaping.

Table 3.12-2
Estimated Miles of Road to be Reconstructed by Alternative[1]

Alternative						
1	2	3	4	5	6	7
925	1,784	1,932	2,182	2,100	2,046	2,371

[1] Estimates are based on the existing miles of maintenance level 1 and 2 roads, existing miles of unauthorized roads incorporated into the LSTA, and the amount of young growth to be treated over the long term (100 + years) for each alternative.

Effects on Log Transfer Facilities

LTFs can adversely affect the marine benthic habitat (plants and animals that live in and on the ocean bottom). Effects are expected from two sources: structural embankment (placing rock in the water) and bark deposition (bark that accumulates underwater). Structural embankment is estimated to cover approximately one-quarter acre per site.

LTFs have affected approximately 2 acres of marine benthic habitat for the average site (Faris and Vaughan 1985). Bark and debris accumulation may decrease over time due to water currents, but there are no reliable estimates on the length of time required before a bark accumulation is completely eliminated. Using this 2-acre average, about 232 acres of marine benthic habitat associated with the existing LTFs on NFS lands have bark accumulations. This is roughly 0.05 percent of the total estuarine area less than 60 feet deep. The biological effects of LTFs are described in the 1997 Tongass Forest Plan Revision Final EIS (USDA Forest Service 1997a). Currently, many timber sale contracts require logs to be loaded directly onto barges rather that placed in the water and bundled into log rafts. This greatly reduces the amount of bark and wood debris that enters the water. In situations where logs are rafted, placing of LTFs in areas where the current will disperse debris can greatly reduce bark accumulation.

The 1991 Land Management Plan Revision Draft EIS estimated that 200 to 350 acres of benthic habitat could be adversely affected by new LTFs over the next 30 years (approximately another 0.04 to 0.08 percent of estuarine habitat under 60 feet deep). This figure was not recalculated for the 1997 Final EIS. The 1991 estimate was based on harvest levels that ranged from 139 to 513 million board feet (MMBF). Harvest levels associated with the alternatives considered under this analysis range from 49 to 421 MMBF. Based on the 2007 LSTA and modeling conducted for this EIS, it is estimated that a maximum of 115 new LTFs would be needed under Alternative 7, resulting in an estimated maximum of 230 additional acres of benthic habitat disturbance. Also, the 1991 estimate and the 2 acres of disturbance per LTF figure, assume that logs would be placed into the water and rafted, rather than loaded onto barges as is currently required on many sales. Therefore, the effects of the proposed alternatives are likely to be less than those anticipated in 1991 or 1997, especially for Alternatives 1, 2, and 3. The effects of continuing operation at existing LTFs are likely to be similar under all alternatives; except under Alternative 1, which would use fewer existing LTFs.

Effects on Off-Highway Vehicle Access

The Forest is in the process of preparing access and travel management plans for the Tongass National Forest. The travel management plans will designate a system of roads and trails for OHV use, and identify if any areas for cross country travel are appropriate and do not cause resource damage. The proposed alternatives would not affect this process because all alternatives include the roaded land base. Travel management decisions are scheduled to be completed in 2009.

Effects on Transportation and Power Transmission Line Opportunities

The Transportation and Utility LUDs proposed under the action alternatives include the transportation corridors covered by Public Law 109-59 and the subsequent Memorandum of Understanding with the State. There would be no difference in how these corridors would be managed under any of the action alternatives. Under all of the alternatives, the Transportation and Utility LUDs would be given priority over all underlying LUDs, including LUDs that do not normally allow road construction.

None of the alternatives would affect other regional transportation opportunities or power transmission line opportunities. No new Wilderness or LUD II areas are proposed under any of the alternatives. None of the alternatives proposes changing any of the currently roaded areas to LUDs that would not allow road construction, road expansion, or transmission line construction.

Wilderness and LUD II lands are identified in the current Forest Plan as Transportation and Utility System “Avoidance Areas.” Utility sites and corridors may be located in these LUDs if an analysis of potential Transportation and Utility LUD corridors has been completed and no feasible alternatives exist outside this LUD.

Cumulative Effects

Cumulative road miles projected for the next hundred years for each alternative are displayed in Table 3.12-1. In addition, there are approximately 3,756 miles of road on non-NFS lands within the Tongass National Forest boundary (including Annette Island). These include 400 miles on state land, 1,252 miles on Sealaska lands, 1,535 on lands owned by Native corporations, and 569 miles on other lands (including towns and cities). There are another 149 miles on lands outside the Forest boundary. Table 3.12-3 displays the maximum cumulative road miles projected for Southeast Alaska over the next 100 years under the proposed alternatives. The total road miles are likely to be an over-estimate because these numbers include unauthorized roads on NFS lands, most of which are expected to be decommissioned.

The road construction projected for non-NFS lands primarily includes roads needed for timber harvest, but also includes roads likely built to serve communities, such as the Juneau access road on the east side of Lynn Canal, which has an approved ROD. This road and other road corridors covered by Public Law 109-59 would, if approved under NEPA and funded, connect additional areas in Southeast Alaska to the continental highway system and improve transportation between communities. These transportation corridors are displayed on the alternative maps. If all roads envisioned under Public Law 109-59 are built, it would have a major effect on transportation in the region.

Table 3.12-3
Estimated Maximum Road Construction and Cumulative Miles of Roads for All of Southeast Alaska by Alternative After Full Implementation (100+ years)[1]

Alternative	New NFS Roads	New Non-NFS Roads	Existing NFS Roads[2]	Existing Non-NFS Roads	Cumulative Roads[2]
1	774	2,657	4,941	3,906	12,278
2	2,079	2,657	4,941	3,906	13,583
3	2,799	2,657	4,941	3,906	14,303
4	4,890	2,657	4,941	3,906	16,394
5	3,874	2,657	4,941	3,906	15,378
6	3,744	2,657	4,941	3,906	15,248
7	5,825	2,657	4,941	3,906	17,329

[1] Approximately 100+ years
[2] Includes unauthorized roads, most of which are likely to be decommissioned.
Estimates are based on the projected harvest for each alternative; therefore, they represent a maximum estimate. If new wood processing facilities and markets are not developed, these levels of harvest are unlikely to occur. Numbers do not include decommissioning of roads.

Reasonably foreseeable hydroelectric projects include the Ketchikan to Metlakatla transmission line, the Swan Lake to Lake Tyee transmission line, the Kake to Petersburg transmission line, and the Angoon hydro project and transmission line.

There is considerable uncertainty concerning the future development of Southeast Alaska's road and transmission system. New roads linking communities and linking Southeast Alaska to the continental highway system would be expensive to build and maintain, and funds have yet to be approved for their construction. The 2004 SATP estimated in 2004 that the cost would be $1.8 billion over 20 years. Most of the funding was anticipated to come from the federal government. To date, there has been no commitment for this level of funding from either the state or federal governments. Similarly, power transmission lines would be difficult and expensive to build and a lack of funding may limit the development of a power transmission system in Southeast Alaska.

Roads associated with timber harvest are based on the projected harvest for each alternative; therefore, they represent a maximum estimate. If new wood processing facilities and markets are not developed, these levels of harvest are unlikely to occur and new road construction would be less than projected in Table 3.12-3. There is also uncertainty concerning the funds to maintain the existing forest road network, place existing roads into storage status, and to decommission roads that are no longer needed. Risks associated with inadequate funding include adverse affects to fish and water quality and increased safety hazards as older roads and stream crossings deteriorate.

Timber

Affected Environment

Introduction

The forests of Southeast Alaska are the main source of raw materials for the region's wood products industry. From 1980 through 2005, the Tongass National Forest accounted for between 18 and 49 percent of the total annual Southeast Alaska timber harvest, averaging approximately 42 percent. During this period, timber harvest on all ownerships in Southeast Alaska ranged from peak levels of just under 1,000 million board feet (MMBF) in 1989 and 1990 to a low of 169 MMBF in 2004. Timber harvested on National Forest System (NFS) lands is available for processing by the local wood products industry but most timber harvested on non-NFS lands is exported. The State increased the sales volume from its forest lands in Southeast Alaska in most recent years to help bridge the gap between national forest harvest and local industry needs. The wood products industry and associated regional employment is discussed in more detail in the *Economic and Social Environment* section of this document.

The forests of Southeast Alaska are primarily the western hemlock-Sitka spruce forest type. This forest type is part of the temperate rain forest that occupies a coastal strip 2,000 miles long from northern California to Southcentral Alaska. The most extensive occurrence of the western hemlock-Sitka spruce type is in Southeast Alaska. Within the Tongass, western hemlock-Sitka spruce stands cover 98 percent of the forest lands. Western hemlock and Sitka spruce comprise the majority of the stocking in this forest type, associated species include, depending on location, yellow-cedar, western redcedar, mountain hemlock, and silver fir (Harris and Johnson 1983). The remaining 2 percent of forest lands support relatively small stands dominated by yellow-cedar, lodgepole pine (shore pine), red alder, or black cottonwood. Western hemlock is used for pilings, poles, railway ties, windowsills, doors, and construction lumber, and has been an important fiber source for pulp. Sitka spruce is used for lumber and commodity products, as well as specialty products, such as piano sounding boards, guitar faces, oars, planking, masts, and spars for custom-made or traditional boats, and ladders. For centuries Alaska Natives have used cedar species for canoes and paddles, housing (along with Sitka spruce), and totem poles. Today, redcedar is primarily used as a roofing material and yellow-cedar has many uses, including boats, utility poles, heavy flooring, framing, and marine decking and piling.

Current Condition of the Forest Land Base

The timber inventory on the Tongass, including the forest type composition, age class distribution, and volume classes, is described in Chapter 3 of the 1997 Tongass Forest Plan Revision Final EIS (USDA Forest Service 1997a). This information was updated with inventory data published in 2001 (van Hees, W. W. S. 2001). Current management practices are also described in the 1997 Final EIS (USDA Forest Service 1997a). Vegetation management practices prescribed under the current Forest Plan, including regeneration methods, reforestation, and intermediate treatments, are described in the standards and guidelines of the 1997 Tongass Forest Plan (USDA Forest Service 1997b). Definitions for each of these practices, how they are applied, and the expected effects on the timber resource are provided.

Forests occupy slightly less than 10 million acres, or approximately 60 percent of the Tongass land area. The remaining 40 percent is non-forested, e.g., water, muskeg, ice, snow, and rock. The forests vary from sparse muskeg forests to heavily timbered stands of 50 thousand board feet (MBF) (long-log bureau scale) per acre or more.

Productive forest land – Forest land capable of producing at least 20 cubic feet of wood fiber per acre per year, or having greater than 8,000 board feet per acre.

Approximately 57 percent of the forest land on the Tongass National Forest (approximately 5.6 million acres) is classified as productive forest land; these lands are considered biologically capable of producing industrial wood products. Approximately 0.5 million acres of the productive forest lands on the Tongass have been harvested to date or have been converted to young growth due to fire or wind. This is approximately 3 percent of the total Tongass land base and 9 percent of the productive forest lands and represents approximately 15 billion board feet of harvested timber. In addition to productive forest lands, the Tongass includes approximately 4.2 million acres of "other forest land." These are lands that are not capable of producing industrial forest products, but are important for watershed protection, wildlife habitat, recreation, and other uses. "Other forest land" is land incapable of yielding crops of industrial wood, usually because of adverse site conditions. These conditions may include sterile or poorly drained soil, subalpine conditions, and steep rocky areas where landslides or avalanches curtail timber development. This land has been called noncommercial or nonproductive forest land in previous documents.

An analysis of timber resource land suitability on the Tongass was completed by the Forest Service for the 1997 Forest Plan Revision Final EIS and updated for this analysis (Appendix A). The National Forest Management Act (NFMA) requires the Secretary of Agriculture to identify lands not suited for timber production due to physical and other pertinent factors. NFMA also included consideration of economic factors in the identification of suitable lands, but the Tongass Timber Reform Act (TTRA) exempted economic considerations as a requirement for identifying suitable lands on the Tongass.

Tentatively suitable lands are lands that have the biological capability, and availability, to produce commercial wood products. To be considered tentatively suitable, the forested land must (36 CFR 219.14):

- Be at least 10 percent occupied by trees or have formerly had such tree cover, and not be developed for non-forest uses;
- Be capable of harvest with available technology to ensure timber production without irreversible resource damage to soil productivity or watershed conditions;
- Be capable of being restocked within 5 years after final harvest; and
- Not be withdrawn from timber production by an Act of Congress, the Secretary of Agriculture, or the Chief of the Forest Service.

In the 1997 Forest Plan Revision Final EIS, it was estimated that there were 2.4 million acres of tentatively suitable lands on the Tongass. The estimated tentatively suitable land base was recalculated for this analysis, and remains at slightly less than 2.4 million acres (Table 3.13-1). Small differences in the tentatively suitable land base are due to updates in the Tongass Geographic Information System (GIS) coverages resulting from changes in land ownership and updates from additional field work, as well as from a different computer measurement method, i.e., using polygon areas rather than extrapolation from a grid system. Figure 3.13-1 illustrates the changes that have occurred to the tentatively suitable forest land base on the Tongass as a result of legislation and the land allocation process over the past 100 years. Of the 2.4 million acres of tentatively suitable land, approximately 1 million acres are estimated to be in land allocations that allow timber harvest and, thus, are mapped as suitable for harvest. After considering factors that are not apparent on aerial photos, such as Class III streams that are not visible under the canopy and unstable areas, there are an estimated 781,000 acres of actual suitable land. Appendix A in the Land and Resource Management Plan describes how the suitable land base was derived.

Table 3.13-1
Land Classification (thousands of acres) of Tentatively Suitable and Suitable Lands

Classification	Acres (thousands)[1]
Total National Forest land (items 1 and 2)	16,774
1. Non-forest land (includes water)	6,918
2. Forest land	9,856
3. Forest land withdrawn from timber production	4,234
4. Available forest land (item 2 minus item 3)	5,621
5. Non-productive forest land	2,339
6. Available forest lands (item 4 minus item 5)	3,282
7. Forest lands physically unsuitable for timber management	572
8. Forest lands with inadequate information	345
9. Tentatively suitable forest land (item 6 minus items 7 and 8)	2,365
10. Tentatively suitable forest land allocated to land use designations that do not allow timber management	1,328
11. Mapped suitable forest land (item 9 minus item 10)	1,037
12. Model implementation factor acreage (MIRF)	255
13. Estimated suitable forest land available for timber production	781

A detailed logging system and transportation analysis (LSTA) was completed in 2007. The LSTA covered all suitable land supporting productive old-growth forest and young growth at least 35 years old, utilizing the Forest's GIS database, orthophotos, aerial photos, existing LSTAs, and National Environmental Policy Act (NEPA) documents (EAs and EISs). Suitable lands with productive old-growth forest and with young-growth stands that may be candidates for thinning in 10 to 15 years were divided into logging settings based on a range of factors, such as topography, visual absorption capacity (VAC), scenery integrity objectives (SIO), Land Use Designation (LUD), and logging system. Areas that could not be roaded because of physical limitations or economics were considered helicopter units. Risk factors were assigned to account for possible "falldown" based on photo interpretation and local knowledge. Possible falldown factors included low merchantable volume, slope stability, karst, steep V-notch streams, and riparian concerns. This information was used to complete an operability analysis for all mapped suitable land on the Forest. Table 3.13-2 summarizes the gross acres and volumes (prior to falldown factors being considered).

Figure 3.13-1
Estimated Tentatively Suitable Forest Land (millions of acres) in the Tongass National Forest, 1907 to Present

Table 3.13-2
Estimated Gross Acres and Volume by Logging System for Productive Old Growth Based on 2007 LSTA

Logging System	Acres	Volume (MMBF)
Ground Based	161,000	4,000
Short-span Skyline	225,000	6,100
Long-span Skyline	25,000	700
Helicopter less than 0.75 mile	184,000	4,800
Helicopter 0.75 to 2.0 miles	72,000	1,700
Helicopter greater than 2.0 miles	57,000	1,400
Total	**724,000**	**18,600**

Ground Based: areas up to 35 percent slope, 800 foot yarding distance
Short-span Skyline: 1,300-foot yarding distance
Long-span Skyline: 1,300-to 2,000-foot yarding distance
Helicopter less than 0.75 mile: yarding distance less than 0.75 mile
Helicopter 0.75 to 2.0 miles: yarding distance more than 0.75 mile, less than 2 miles
Helicopter greater than 2.0 miles: yarding distance more than 2 miles
Source: Tongass 2007 LSTA includes mapped suitable lands supporting productive old-growth forest and supporting young growth at least 35 years old. Mapped suitable acres do not include falldown factors. Numbers may not appear to add correctly due to rounding.

Current Condition of the Timber Resource

There are six conifer forest types within the Tongass. Western hemlock and western hemlock-Sitka spruce forest types account for approximately 96 percent of the tentatively suitable lands and about 75 percent of all forest lands on the Tongass. The remaining forest lands are occupied by the yellow-cedar (sometimes referred to as Alaska yellow-cedar), western redcedar, lodgepole pine, and Sitka spruce forest types (USDA Forest Service 1997a).

Age Class Distribution. The Tongass is a mix of old-growth stands and naturally regenerated young-growth forest, which consists of both wind-created and harvest-created young-growth forest. Harvest-created young-growth amounts to less than 7 percent of the total forest land area. Suitable forest lands are classified into five stand conditions: 1) old-growth sawtimber, 2) young growth sawtimber, 3) pole timber, 4) seedling and sapling, and 5) non-stocked. For timber inventory purposes, stands of trees 150 years old or older are designated as old growth. More than 85 percent of forest lands meet the criteria for old-growth sawtimber (Table 3-13-3).

To help define tree ages on the Tongass, Farr and McClellan (unpublished manuscript) measured and analyzed age data from 67 plots located throughout the Tongass (excluding the Yakutat Area). They found that 90 percent of all overstory trees were more than 180 years old; 84 percent were more than 200 years; 47 percent were more than 300 years; 15 percent were more than 400 years; and 5 percent were more than 500 years old.

Forests less than 150 years cover approximately 0.7 million acres; forests that are 150 years of age or greater cover nearly 5 million acres. Table 3.13-3 lists the total acres of productive forest land and the acres that are suitable for timber production within two broad age classes.

Table 3.13.3
Estimated Age Class Distribution of All Productive Forest Land and Suitable Productive Forest Land (acres)

Age (Years)	All Productive Forest Lands[1]	Suitable Forest Lands[1,2]
0 to 149	689,000[3]	250,000[3]
150+	4,951,000	532,000
Total	5,640,000	781,000

[1] Numbers may not appear to add correctly due to rounding..
[2] Mapped suitable acres adjusted (reduced) for falldown (MIRF).
[3] Includes natural young growth and regeneration after harvest.
Source: Tongass National Forest GIS database

Table 3.13-4 displays the acres harvested by age class. Approximately 45 percent of the area harvested over that past century is no longer suitable, due to changes instituted by Congress or due to Forest Plan decisions. For example, areas designated as Wilderness or LUD II by Congress are no longer tentatively suitable. Tentatively suitable areas harvested within the 1,000-foot-wide beach fringe, riparian areas, and old-growth reserves are no longer suitable for timber harvest.

Table 3.13.4
Estimated Age Class Distribution of Harvested Stands (acres)

Age Class (Years)	All Forest Lands[1]	Suitable Forest Lands[1,2]
0 to 35	282,000	163,000
36 to 70	162,000	64,000
>70	10,000	1,000
Total	**455,000**	**228,000**

[1] Numbers may not appear to add correctly due to rounding..
[2] Mapped suitable acres adjusted (reduced) for falldown (MIRF).

Species Mix and Log Types

Timber harvest on the Tongass generally results in a mix of species and log types. The majority of the logs cut in most sales are western hemlock; Sitka spruce is the second most common species. Together these two species account for the majority of the harvest, based on the SPECTRUM model results (refer to Appendix B for a discussion of the Spectrum model) and the estimated species mix identified in the 1997 FEIS for the current Forest Plan. Yellow-cedar and western redcedar account for most of the remaining volume. Cedar, especially yellow-cedar, often commands high prices on the export market and is generally exported (refer to the *Economic and Social Environment* section for discussion of utilization).

Trees harvested from old-growth stands on the Tongass often contain three types of logs: sawlogs, utility logs, and cull logs. Figure 3.13-2 shows one possible example of a tree containing all three log types. Sawlogs are logs that come from that portion of the tree that is of suitable size and quality to be cut into dimension lumber. Sawlogs usually come from the lower portion of the tree, the part of the tree with larger diameter logs. Higher quality sawlogs come from that portion of the tree with fewer branches, which can result in lumber with fewer knots, while lower quality sawlogs often come from that portion of the tree that still retains a live crown. Utility logs are logs that cannot be used to produce lumber but are suitable for chips. They contain at least 50 percent sound wood. Utility wood is also produced from portions of sawlogs that cannot be cut into lumber (refer to Figure 3.13-2). The third type of logs, referred to as cull logs, are logs that do not have enough sound wood to be merchantable, even for chips. These logs are usually left in the woods and contribute to large woody debris (LWD) component and structure left on the forest floor.

Timber Inventory Methodology and Scientific Accuracy

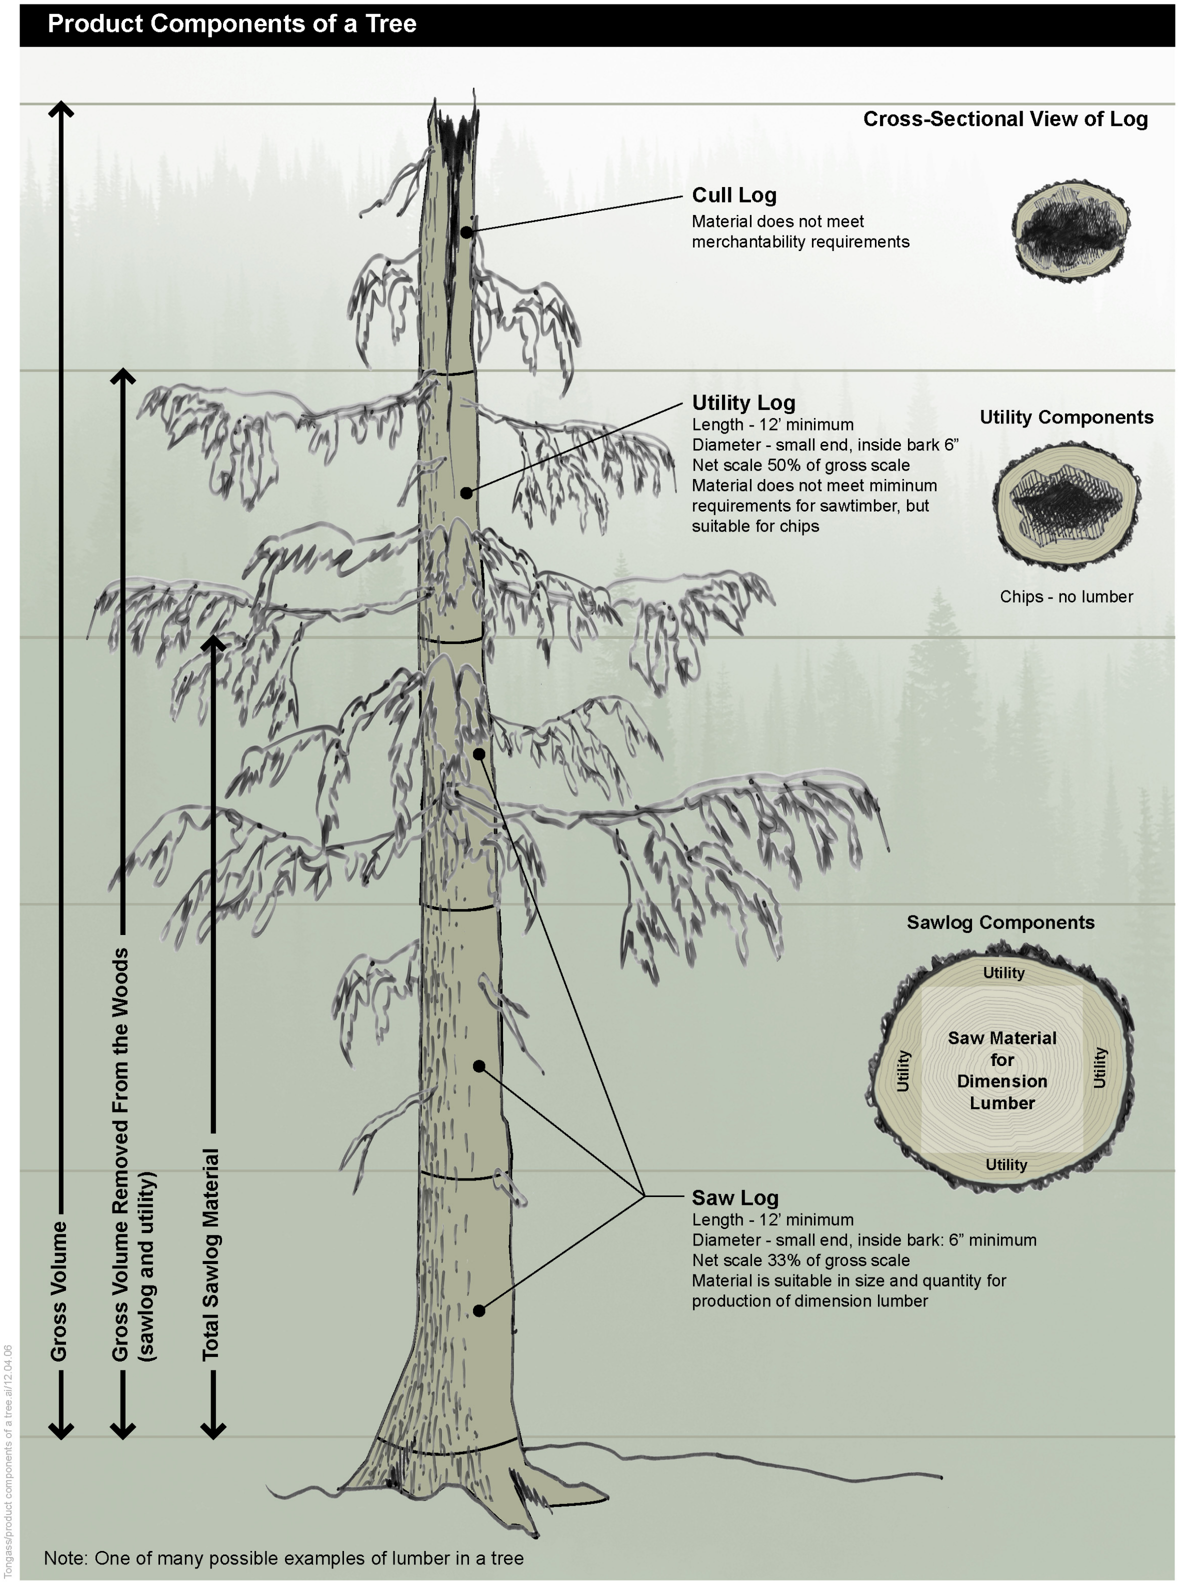
The first Southeast Alaska-wide timber inventory began in 1953 and was completed in 1958. Due to the extensive area to be covered, the inventory was subdivided into Juneau, Sitka, Petersburg/Wrangell, Yakutat, and Ketchikan/Craig working circles. Ten years later, a portion of the original inventory was re-measured to improve estimates of growth and mortality trends in young-growth stands in Southeast Alaska. Young-growth stands, for timber management considerations, were defined as being less than 150 years old and normally less than 20 inches in diameter (measured at “breast height”).

A complete re-inventory program to re-evaluate Southeast Alaska’s forest area and volume began in the early 1970s and was completed by 1975. Several new categories of information were collected, including data to evaluate the level of stocking (the number of existing trees compared to full stocking of trees for a site), strata classes (timber categorized by several attributes such as species, decadence, stocking, site index, and board feet per acre), soils, slope, a better definition of harvest categories, and a redefinition of quality guides. Detailed data, such as risk class and soil microsite, were collected on individual trees to better estimate their potential for timber management considerations.

In 1979, an extensive point sampling system inventory developed for the Tongass Land Management Plan gathered specific information across the Tongass to provide specific information for the completed 1970s forest inventory. In the early 1980s, this inventory was redesigned by the three Administrative Areas (Chatham, Stikine, and Ketchikan, which correspond to the north, central, and southern portions of the Tongass). Field data collection for this inventory was completed in 1985.

The 1980s inventory was designed to estimate the standing volume on the Forest within certain error limitations. The sampling errors for area and volume met the requirements of Forest Service Handbook (FSH) 2409.13 (plus or minus 10 percent per billion net cubic feet at a 68 percent confidence level). A review of the inventory methodology and results was conducted in September 1989 by a Forest Service Biometrician, Jim Brickell. He concluded that the inventory results are reliable as an

Figure 3.13-2
Product Components of a Tree



assessment of forest areas and volumes at the forest and area levels (Brickell 1989). Although the data for the inventory were gathered on a forest-wide basis, the inventory was designed to be specific only to the Administrative Area level. The inventory was not designed to collect all timber resource information, nor was it designed for comparison of individual plot results to timber type map polygons or volume strata.

The results of the 1980-85 inventories showed that the Tongass National Forest had a net growing stock of 22.7 billion cubic feet on 4.3 million acres of available lands (5.3 thousand cubic feet per acre). This would indicate that the 2.42 million acres of tentatively suitable land had approximately 12.8 billion cubic feet of growing stock. The net growing stock for the 5.7 million acres of productive forest land was 31.5 billion cubic feet, or 5.5 thousand cubic feet per acre (approximately 27.5 MBF per acre).

Forest Strata

The Forest established four volume classes of commercial timber in the 1979 Forest Plan (amended 1985). Using net inventory volumes per acre, these classes are:

- Class 4: 8,000 to 20,000 board feet
- Class 5: 20,001 to 30,000 board feet
- Class 6: 30,001 to 50,000 board feet
- Class 7: 50,001 board feet or greater

There were a number of concerns from within and outside the agency regarding the reliability of this information (usually referred to as the volume class map). Therefore, a study addressing concerns about the volume class map reliability was commissioned in 1989. It concluded that there was no statistical difference among volume classes 5, 6, and 7 with respect to mean board feet per acre, and the existing volume class map should not be used to determine volume per acre (Brickell 1989).

The volume class map was used by the Alaska Region to calculate long-term timber sale contract timber volume proportionality, as required by Section 301 of TTRA. However, this procedure was successfully challenged in court by The Wildlife Society, Alaska Chapter. The court disputes over TTRA Section 301 proportional harvest methodology were settled, with issuance of an updated Forest Service Handbook Supplement (Region 10, FSH 2409.18 Supplement No. 2409.18-96-1), and alternative methods of assigning timber volume (or the capability to produce different timber volumes) to lands currently supporting old-growth forests were considered for the 1997 Forest Plan Revision. Five different options were studied and evaluated (Julin and Caouette 1997). Statistical analysis indicated that three strata can be distinguished for the available forest lands (lands not legislatively or administratively withdrawn) using the existing inventory and additional information on soils and slope. The polygon characteristics of the three-strata approach are displayed in Table 3.13-5. In the development of the new size-density model (SDM) (see *Biodiversity* section), these strata were redefined using improved information on hydric soils and aspect. Table 3.13-5 is based on these redefined strata. These strata were used to model timber outputs for this analysis (refer to Appendix B for a discussion of the SPECTRUM model).

Table 3.13-5
Tongass National Forest Strata Characteristics–Productive Old-Growth Forest

Geographic Area	Trees/ Acre	Gross Volume (MBF/ Acre)	Net Sawlog Volume (MBF/Acre)	Net Utility Volume (MBF/Acre)	Total Net Sawlog and Utility Volume (MBF/Acre)
North Islands[1]					
Low	102	17.8	11.1	1.8	12.9

[1] North Islands: Chichagof, Baranoff, Admiralty, and associated islands; North Mainland: mainland north of the Stikine River; South Islands: Kupreanof, Mitkof, Kuiu, Prince of Wales, and associated islands; South Mainland: mainland south of the Stikine River.
Refer to USDA Forest Service 2006, SDM Data for documentation on why forests were grouped in these geographic areas. Numbers not exact due to rounding.

While the three-strata approach is useful for estimating timber volume for forest planning purposes, it is not a good tool for identifying other important forest elements, including forest structure, ecosystem diversity, and wildlife habitat. For example, two stands may have the same volume, but one may be a dense stand of medium-sized trees with a single canopy layer, while the other stand may be a combination of widely spaced large overstory trees and two or three lower canopy layers containing small- and medium-sized trees. The SDM, which uses a combination of two common forest measurements, tree sizes and tree densities (Caouette et al. 2001), has proven to be a better tool for representing these other forest elements. Using tree sizes and densities provides a more comprehensive forest measuring system for describing habitat than timber volume (Spies and Franklin 1991). The new SDM (Caouette and DeGayner 2005) is described and used in the *Biodiversity* and other sections.

Non-National Forest System Lands

The State of Alaska, Native village corporations, Sealaska (the Native regional corporation) and individuals own over 1,050,000 acres of land in Southeast Alaska, inside the Forest boundary. Approximately 408,000 acres of this land currently consists of productive old-growth forest and 351,000 acres consists of young growth. This means that approximately 46 percent of the original productive old growth has been harvested (as of 2006 based on GIS analysis and information provided by the landowners). Most timber harvested from state lands in recent years has been processed locally, while timber harvested from University Trust and Mental Health Trust lands has been exported.

Current Practices

Regeneration Methods

Even-aged Systems. This system includes clearcuts, seed tree, and shelterwood harvest methods. These methods are described in detail in Appendix G of the 1997 Tongass Land Management Plan Final EIS. Under an even-aged system, the intention is to replace the entire (or nearly the entire) stand with a new crop of trees that are all of the same age. Under NFMA, clearcutting can only be used when it is the optimum system. This is determined through a site-specific prescription approved by a certified silviculturist. Also under NFMA, a stand must have reached at least 95 percent of culmination of mean annual increment (CMAI). This is the point at which the stand reaches its highest average growth. The exact age that this occurs varies by site and stand treatment. A stand on a high site will generally reach CMAI sooner than one on a lower site. However, stand treatments, such as precommercial thinning and commercial thinning, will generally extend the period of fast growth, causing the stand to take longer to reach CMAI.

Clearcutting, with reliance on natural seeding, has been the most commonly used silvicultural system in the Sitka spruce-western hemlock forest type of Southeast Alaska (Ruth and Harris 1979, Deal et al. 2002). Clearcutting is used where timber production is the primary use and where it is the optimal method. The clearcutting method is favored for several reasons. Clearcutting increases exposure to the sun, which raises soil temperature, speeds up organic decomposition, and thus improves soil productivity. Sitka spruce is less tolerant of shade than western hemlock (USDA Forest Service 1990); therefore, in the mixed spruce-hemlock forests of Southeast Alaska, the open conditions created by clearcutting favor the regeneration of Sitka spruce (Ruth and Harris 1979). Clearcutting in stands infected by dwarf mistletoe substantially reduces infection in the regenerated stand (Shaw and Hennon 1991). Logging costs are lower than with other systems, and the clearcut method has proven very successful in the regeneration (regrowth) of healthy forested stands (refer to Appendix G in the 1997 FEIS for additional discussion).

A variant of this system, referred to as clearcutting with reserves, involves retaining approximately 10 percent of the stand, either in single trees or in small groups. This method is generally used to meet scenery or wildlife needs in areas where timber production is the primary goal.

In 1992, the Chief of the Forest Service directed that the even-aged system (clearcutting) be limited to areas where it is essential to meet Forest Plan objectives. Clearcutting has traditionally been used in the hemlock-spruce forests of Southeast Alaska to reduce mistletoe infection by eliminating infected trees from the overstory, reduce heartrot and stem diseases that may result from logging damage to leave trees, and to eliminate the risk of blowdown of residual trees. In addition, it requires fewer miles of road for a given volume (Ruth and Harris 1979, USDA Forest Service 1983). Because more volume is harvested from each acre than would be the case under uneven-aged management, many fewer acres are impacted for the same harvest volume.

Two-aged Systems. In this system, for example, up to 30 percent of a stand is left as residual (or reserve) trees, either as single trees or in patches, and the rest of the stand is harvested. The reserve trees remain unharvested and provide structural diversity and an older aggregation of trees within the otherwise young-growth stand. This system has been used on the Tongass to meet scenery objectives. Logging costs can be higher because of the need to protect the reserve trees.

Experience in other regions indicated that retaining overstory trees led to regeneration of more shade-tolerant species (which would favor hemlock over Sitka spruce in Southeast Alaska), reduced growth, increased dwarf mistletoe infection in understory trees, and resulted in windthrow of overstory trees (Harris and Farr

1974). However, a retrospective study of 18 partial cut stands in Southeast Alaska found that partial cutting had little effect on tree species composition, diameter growth, or dwarf mistletoe levels (Deal and Tappeiner 2002, Deal 2002). Mortality of residual trees was only marginally higher in partial cut stands than in uncut stands; although the location of these stands may have contributed to the relatively low level of wind damage. The stands sampled in this study were all below 100 feet in elevation and within 1.25 miles of the shoreline. Stands on exposed south-facing ridges and on slopes are likely to have a greater risk of windthrow (Nowacki and Kramer 1998). Windthrow may be of particular concern because one of the predicted outcomes of climate change in Southeast Alaska is an increase in the frequency of severe wind storms. Juday et al. (1998) considered it highly likely that there would be increased blowdown across Southeast Alaska in the future.

Uneven-aged Systems. This system typically involves harvesting of single trees or of small groups of trees (usually less than 2 acres) from within a stand. This method maintains a multi-aged, multi-layered stand structure by removing some trees in all age groups. It has been used on the Forest to meet scenery and wildlife habitat needs. Uneven-aged management often involves higher costs and affects larger areas than would be needed for the same harvest volume under an even-aged or two-aged system (Ruth and Harris 1979). Also, the frequent entries in the stand to remove individual or small groups of trees increases logging costs and the risk of damaging the remaining trees (USDA Forest Service 1983).

There is little scientifically documented experience with uneven-aged harvest in Southeast Alaska (McClellan et al 2000). Deal (2001) concluded that it may closely mimic the natural disturbance regime of Southeast Alaska based on a retrospective study of 18 partial cut stands. Stand structures were similar to uncut old-growth stands, and cutting had no significant effect on species composition (Deal and Tappeiner 2002). Uneven-aged systems have potential benefits, including protection of wildlife habitat, scenery, and slope stability as well as the maintenance of biological diversity (McClellan et al. 2000).

Young-Growth Management

Managing young-growth forests in Southeast Alaska is likely to become an increasingly important component of forest management on the Tongass in the coming years. Young-growth stands can be treated through thinning and other intermediate treatments to concentrate growth in fewer, larger trees, improve lumber quality, and/or to enhance habitat conditions for wildlife. Zaborski et al. (2000) concluded that the types of treatments applied to young stands will have a profound effect on the types of materials available in the future, including log diameter, knot size, and wood strength.

Over 100,000 acres have been precommercially thinned on the Tongass since 1979. In recent years, precommercial thinning has averaged approximately 5,600 acres per year. The Forest has much less experience with other young-growth management techniques, such as pruning and commercial thinning.

Barbour et al: (2005) estimated that a precommercial thinning at age 20 with a spacing of 12 by 12 feet would produce more merchantable wood volume at age 70 than wider spaced thinnings. However, there is a trend toward wider tree spacing in precommercial thinning prescriptions to maintain or enhance understory plant cover. These treatments could increase taper and stimulate the production of epicormic branches (in spruce) and knot size. These changes could adversely affect wood strength and stiffness (McClellan 2005). There is also a concern that wider spacing may increase the occurrence of fluting on sites where this is a problem (Julin et al. 1993, Holsten et al. 2001).

Pruning removes lower branches and can increase future lumber quality; however, care must be taken not to remove too much of the live crown. Petruncio (1994) recommends that 33 percent of the live crown (no more than 40 percent) can be removed in a western hemlock-Sitka spruce forest without affecting tree growth. Pruning may also increase epicormic branches in Sitka spruce. Deal et al. (2003) reported that 232 out of 236 Sitka spruce had between 9 and 11 sprouts per meter of tree bole. Significantly more large sprouts were produced in the highest pruning lift.

There has been increased interest in commercial thinning in recent years, not only to improve timber values, but as a tool to improve wildlife habitat. Studies in other forest types in the Pacific Northwest indicate that stand structures that are similar to old-growth forest conditions can be developed through thinning (Thysell and Carry 2000). However, there are many unanswered questions as to how to implement thinning treatments that provide a sustainable source of high-value wood products while maintaining biological diversity (Zaborske et al. 2000). In a study comparing the lumber harvested from thinned and unthinned, 90-year-old stands on the Tongass National Forest, Christensen et al. (2002) found that there was no difference in volume recovery or lumber grade in thinned and unthinned Sitka spruce. For western hemlock, the unthinned stands produced more wood volume, but the thinned stands produced more high-grade lumber. There was no difference in the bending module of elasticity for lumber produced from thinned or unthinned stands for either species.

There is also increased interest in managing young-growth stands to increase and maintain understory vegetation, especially as forage for deer and other wildlife. Hanley et al. (2005) noted that much research is needed on new approaches involving thinning of older stands and on including red alder in the secondary successional sequence. Zaborske et al (2002) found that thinning greatly increased forage production, though the amount of useful forage produced varied by the type of thinning implemented. Refer to the *Wildlife* section for a discussion of habitat manipulation.

In additional to their continuing research on managing young forests, scientists at the Pacific Northwest Research Station joined with the Tongass National Forest in 2001 to establish an operational-scale adaptive management study of young-growth management options. This program, called the Tongass-wide Young-Growth Studies (TWYGS), is designed to evaluate the potential benefits of treating young-growth stands to increase wildlife habitat and wood production. Currently, TWYGS includes experiments that test the effectiveness of alder interplanting, precommercial thinning, and pruning.

Yarding Methods

On the Tongass, most logs have been yarded downhill using cable logging systems such as highlead and skyline. Access has usually been from valley bottoms, because road building on steep slopes is difficult and costly. Most logging occurs inland, with logs transported via road systems to marine access points, also referred to as log transfer facilities (LTFs), at tidewater (see the *Transportation and Utilities* section). Harvest by tractor (shovel yarding) has proven effective on flat to moderate slopes; it is not practical on steep slopes. Harvest by helicopter has been limited in the past but is increasing; it is typically the costliest method, but also has fewer adverse effects on other resources.

Yarding methods can be divided into three "operability" classes, which relate to the methods necessary to harvest and transport trees under various conditions. Normal operability includes the standard ground-based and cable logging systems used in areas where access is relatively easy and helicopter logging with distances of up to 0.75 mile. These areas have the lowest logging costs. Difficult operability includes long-span cable systems and helicopter logging with distances between 0.75 and 2.0 miles, occurring where ground access is difficult or not possible. Difficult operability involves higher costs. The third class, isolated operability, consists of isolated stands 2.0 miles or more from a helicopter landing site. These tend to be uneconomical under even high timber markets.

The recent LSTA indicates that approximately 89 percent of the suitable timber land would be accessible using normal harvest methods, 10 percent would be difficult, and 1 percent would be isolated. When economic and environmental risk factors are considered, additional areas are likely to be identified as difficult or isolated during project planning. Risk factors assigned by the LSTA team and district personnel, indicate that about 85 percent of the suitable acres with old-growth forest would be in the normal category.

Tongass Timber Sale Program

One objective of the Alaska National Interest Lands Conservation Act (ANILCA) was the maintenance of timber supply for the Southeast Alaska timber industry because of its contribution to the local and regional economies of Southeast Alaska. For similar reasons, TTRA (Section 101) directs the Forest Service to seek to provide a supply of timber from the Tongass that meets annual market demand and the market demand for each planning cycle to the extent consistent with providing for the multiple-use and sustained-yield of all renewable resources. The planning cycle is assumed to be the 10- to 15-year period between Forest Plan revisions.

The Tongass timber program is part of a long-term cooperative effort among the federal government, the State of Alaska, and local governments to provide economic diversity and stability in Southeast Alaska and more year-round employment. During the 1920s, the Forest Service proposed several long-term sales to help establish a pulp industry in Southeast Alaska. The objective was to provide a sound economic base in Alaska through establishment of a permanent year-round pulp industry. The Forest Service established requirements to process timber in Alaska, including the construction of pulp mills, via 50-year timber sale contracts awarded in the early 1950s. The first successful sale was made in 1951, and the construction of a pulp mill was completed at Ward Cove near Ketchikan in 1954. This long-term contract was held by Ketchikan Pulp Company (KPC). During the 1950s, the Forest Service offered three additional long-term sale contracts. The belief was that a long-term sale was necessary to ensure the supply of timber and attract an integrated wood products industry to Alaska.

These long-term timber sale contracts are no longer operating. The U.S. Plywood-Champion Paper contract in the Juneau District was canceled by mutual consent in 1976; no operations were performed on the ground. The Pacific Northern Timber Company contract, located on the Wrangell District, required the construction and operation of both a sawmill and pulp mill for 50 years. Only the sawmill was built and operated and the contract was limited to 25 years. All ground activities for the Wrangell Unit were completed in 1981 (USDA Forest Service 1997a). The Alaska Pulp Corporation (APC) closed their Sitka pulp mill in 1993 and the Wrangell sawmill closed in 1995. Their contract was terminated by the Forest Service in 1994. An end to the KPC contract, which was due to expire in 2004, was negotiated in February 1997. The KPC pulp mill closed in 1997.

The average annual timber harvest on the Tongass was about 40 MMBF per year from the early 1900s to 1952. Timber harvest averaged about 358 MMBF per year (sawlog and utility) for the next 45 years after establishment of the long-term contracts in the 1950s. This volume was generated primarily from the KPC, Pacific Northern Timber, and APC contracts. Harvests peaked in 1973 at approximately 591 MMBF and then declined to a low of about 181 MMBF by 1985 (Figure 3.13-3). Harvest levels rose again until 1990 and then declined to their current levels.

Long-term sales comprised almost three-quarters of the timber volume made available during the period of 1980 through 1991 (USDA Forest Service 1997a; Table 3-74). Between Fiscal Years 1980 and 1995, an annual average of 247 MMBF of volume was made available to the long-term contract holders. Because of market fluctuations, appeals and litigation, and other factors, the long-term contract holder annual average harvest between 1980 and 1995 was about 249 MMBF. Total annual average harvest was approximately 340 MMBF over the same time period. KPC continued to harvest timber until 2000 (Figure 3.13-3). Annual timber harvest averaged approximately 46 MMBF from 2001 to 2005. This represents approximately 13 percent of the total average annual harvest from 1980 to 1995 (340 MMBF). This decrease is largely due to the termination of the long-term contracts with APC and KPC. However, there has also been a decrease in harvest by independent timber operators since 1990 (Figure 3.13-4). Independent timber operators harvested an average of more than 100 MMBF per year between 1980 and 1990. Harvest peaked at 173 MMBF in 1990, about 37 percent of that year's total harvest. Independent harvest decreased sharply in the early 1990s, with a low of 27 MMBF harvested in 1996 (refer to the Economics and Social section for a discussion of this decline). Annual independent harvest has continued to fluctuate since then, ranging from 34 MMBF in 2002 to 67 MMBF in 2000 (Figures 3.13-3 and 3.13-4).

The current Tongass timber program is composed of a large sale program, a small sale program, and a firewood and personal use program. Harvest volumes averaged 45 MMBF between 2002 and 2006, notably lower than the average annual harvest of 358 MMBF for 1952 to 1997 (Table 3.13-6 in the following sub section) and the Allowable Sale Quantity (ASQ) of 267 MMBF per year approved in the 1997 Record of Decision.

The timber sale program has been in transition since the end of the long-term contracts. Many small operators are in the process of developing direct markets for value-added products, such as molding, tongue-in-groove, paneling, and furniture. There were 15 small mill operators on Prince of Wales Island alone as of August 2005 (Petersen and Bruns 2005). The Forest has created a program to make wood available to small operators, referred to as the microsale program. This program makes dead and down wood with a value of $10,000 or less available to local purchasers by competitive means. The Forest Service and the University of Alaska have created the Ketchikan Wood Technology Center to focus on ways to help the local timber industry. Among other things, the center has developed log grades for Alaskan wood products.

The primary sources of timber in Southeast Alaska are the Tongass National Forest, private corporations (principally Alaska Native Corporations formed through the Alaska Natives Claims Settlement Act [ANCSA]), and the State of Alaska (USDA Forest Service 1997a; Table 3-75). Timber harvest patterns are discussed in greater detail in the *Economic and Social Environment* section of this document.

Timber Sale Management

The Forest Service employs a "pipeline" approach to timber sale planning to provide a stable timber sale program and a continuous flow of timber to regional timber processors. The resulting program is complex and requires that the Forest Service manage four "pools" of timber volume, commonly referred to as the timber pipeline:

- **Timber volume identified in the Forest Service's 10-year Timber Sale Plan.** This pool contains sales available for future timber sale planning and preparation.
- **Timber volume in preparation.** This pool contains sales that are being analyzed and are undergoing public comment through the NEPA process. This can take from 2 to 4 years to complete and ends when a NEPA decision is made.
- **Timber volume available for sale.** This pool contains NEPA-approved sales. Administrative appeals have been resolved, and litigation, if any, has also been resolved. This volume is available to program managers to schedule for sale offerings. Managers need to maintain enough volume in this pool to be able to schedule future sale offerings in an orderly manner and of the size and configuration that best meets regional demand. The Forest Service tries to announce probable future sale offerings at least a year in advance to allow potential purchasers an opportunity to conduct their own evaluations of these offerings in order to determine whether to bid and, if so, how much to offer.
- **Timber volume under contract.** This pool contains sales that have been sold, but not yet harvested. Timber contracts typically give the purchaser 3 to 5 years to harvest or remove the timber purchased. The Forest Service attempts to maintain about 3 years of unharvested timber volume under contract to purchasers. This practice is not limited to the Alaska Region, but is particularly relevant to Alaska because of the nature of the land base. The relative absence of roads, the island geography, and steep terrain mean that much of the timber is isolated and timber purchasers need longer-than-average lead times to plan operations, stage equipment, set up camps, and construct roads prior to beginning harvest.
- Timber sales can take from 3 to 5 years to complete. Sales offered by the Forest Service vary in size to meet the needs of different purchasers. The time taken to complete a sale may vary with the size of the offering. Uncertainty and delays may be introduced through appeals and litigation. The pipeline approach and the variable length of the timber sale process generally make it difficult to draw a direct relationship between particular sales and regional timber demand. Not all of the volume offered for sale since 2001 has been sold. Some sales did not receive bids and many others have been held up by appeals and/or litigation (Table 3.13-6). There were both project- and Forest Plan-related appeals and litigation (i.e., the Roadless Rule).

Timber under Contract

As of May 19, 2006, there were approximately 70 timber sales with approximately 118 MMBF of timber volume under contract on the Tongass National Forest. Although there are nearly 50 timber companies and individuals that either purchase timber or have shown an interest in purchasing timber from the Tongass, over 85 percent of the timber under contract is under contract with four operators: Viking Lumber Company (49.8 percent), Pacific Log and Lumber (26.1 percent), Icy Straits Lumber (7 percent), and Alcan Forest Products (5 percent). These figures do not include all microsales (sales under $10,000). Timber under contract is discussed in greater detail in the *Economic and Social Environment* section.

Long-term sales comprised almost three-quarters of the timber volume harvested during the period of 1980 through 1995 (Figure 3.13-3). During this period, an annual average of 249 MMBF of volume was harvested under the long-term contracts. During this same period, independent sales averaged 91 MMBF per year, ranging from a low of 36 MMBF in 1983 to a high of 173 MMBF in 1990.

The primary sources of timber within Southeast Alaska are the Tongass National Forest, private corporations (principally Alaska Native Corporations formed through ANCSA), and the State of Alaska (Table 3.13-7). Between 1980 and 1990, harvest from the Tongass contributed about 50 percent of the timber supply in Southeast Alaska. However, timber harvest since 1990 has fallen to less than 50 percent of total supply. The Tongass contributed approximately 23.6 percent of the total timber supply in Southeast Alaska between 2001 and 2005.

Table 3.13-6
Volume of Timber Offered, Sold, and Harvested from the Tongass National Forest for FY 2002-2006 (MMBF) [1]

Fiscal Year	Offered	Sold	Harvested
2002	56.9	24.4	33.8
2003	88.8	30.5	51.3
2004	72.6	87.1	46.4
2005	110.4	67.3	49.6
2006	24.0	85.0	43.0
5-Year Average	**70.5**	**58.9**	**44.8**

Timber Demand

Demand for timber products from the Tongass National Forest is discussed in detail in the *Economic and Social Environment* section.

Environmental Consequences

The analysis of the potential effects of the alternatives addresses the following questions:

- How much land would be allocated to timber production?
- What silvicultural systems and vegetative practices would be utilized?
- What would the ASQ be under each alternative?
- What projected log grade or quality would be provided?
- What would the product mix be, in terms of sawlogs and utility logs?
- What would the long-term sustained yield (LTSY) be under each alternative?
- What are the factors that affect the attainment of the ASQ?
- What would be the future condition of the Forest in 150 years?

The analysis of timber supply and demand for timber products, as well as how existing sales under contract and timber volume in preparation may be affected by the alternatives, is discussed in the *Economic and Social Environment* section.

The effects on the timber industry infrastructure and employment levels are also discussed in that section.

Suitable Timber Lands

There are approximately 2.4 million acres of tentatively suitable lands, as defined by NFMA regulations (36 CFR 219.14(a)) and Section 102 of TTRA. Slightly over 1 million acres of this is mapped as suitable under Alternative 5 (No Action) However, as described below (see factors affecting the ASQ), only an estimated 781,000 acres are suitable for harvest and only 687,000 acres are scheduled for harvest under Alternative 5. This includes old-growth and young-growth forest. Appendix A of the Forest Plan contains a detailed discussion of the tentatively suitable determination process. The amount of suitable land would vary by alternative.

Table 3.13-8 displays the distribution of forest lands, tentatively suitable lands, and suitable lands by alternative. The amount of suitable land that would be scheduled for harvest in order to meet the ASQ under each alternative is also shown. The amount of suitable land would vary from less than 2 percent of the Forest under Alternative 1 to nearly 7 percent of the Forest in Alternative 7. No alternatives have a suitable land base greater than 1.2 million acres. Differences result from assigning the Old-growth Habitat, Remote Recreation, Semi-remote Recreation, and other non-development LUDs. Alternatives 1, 2, 3, 5, and 6 have substantial acres of tentatively suitable lands assigned to the Old-growth Habitat LUD. Alternative 4 uses a different strategy to provide old-growth habitat and primarily assigns land to the Old-growth Habitat LUD in four Biogeographic provinces. In other areas, 33 percent of the productive forest land in each Value Comparison Unit would be maintained in an old-growth condition. Alternative 7 would have the least restriction on harvest in old-growth forest; it does not include Old-Growth Habitat LUDs nor would it have minimum old-growth retention requirements.

Table 3.13-8
Land Classification (thousands of acres), Tentatively Suitable and Suitable Lands[1]

Classification	Alternative 1	2	3	4	5	6	7
Total National Forest land (Items 1 and 2)	16,774	16,774	16,774	16,774	16,774	16,774	16,774

Removing land from the suitable land base reduces both potential ASQ and long-term timber growth and yields. While the effect is not perfectly linear, the magnitude of the reduction is generally related to the proportion of lands removed. The timber production lost is irretrievable but is not irreversible. If future designation of these lands is changed to allow timber management, it would be possible to resume timber management activities. Where land is dedicated to road construction or development of facilities, minerals, or rock excavation, the loss of land for timber production is generally irretrievable and may be irreversible.

Silvicultural Systems and Practices

This section describes vegetation management practices prescribed in the Forest Plan, including regeneration methods, reforestation, and intermediate treatments. Definitions for each of these practices, how they will be applied, and expected effects on the timber resource are provided.

Regeneration Harvest Methods

For modeling and planning purposes, the current Forest Plan considered the three regeneration methods discussed under Regeneration Systems: even-aged system, two-aged system, and uneven-aged system (group selection). These same methods were also considered in this Plan Amendment. This does not mean that these are the only these regeneration methods that will be used on the Tongass. Other even-aged methods such as shelterwood, which may be utilized to meet specific objectives, would be similar to clearcut with reserves in regards to appearance and effects (or to clearcuts if the shelterwood is later cut). For this reason, only these three methods were modeled and displayed. Appendix G of the 1997 Land Management Plan Revision FEIS contains detailed descriptions of the various silvicultural systems and their advantages and disadvantages. In addition, other regeneration methods may be applied on a limited scale to test their utility in achieving other forest management objectives.

Implementation of any Forest Plan alternative would include a full array of silvicultural prescriptions, including modification of these methods, depending on the site-specific conditions. The choice of the regeneration method and rotation length would be based upon site-specific analysis done at the project level, would consider multiple resource needs and objectives, and would include the rationale for using the selected regeneration method. This would be documented in the silvicultural prescription, which must be approved by a certified silviculturist.

Table 3.13-9 displays the annual number of acres estimated for each of the three main regeneration methods by alternative for the first and fifth decades of the Plan (based on the SPECTRUM model outputs). The acreages displayed are for modeling purposes in order to estimate Forest Plan outputs and do not limit the manager's ability to use any regeneration method to best meet project goals and objectives. The model used to develop the current Forest Plan (FORPLAN) estimated that 80 percent of the harvest under the selected alternative (the current Forest Plan) would be even-aged and the remaining 20 percent would be two-aged. Sales sold in recent years have averaged 76 percent even-aged harvest, 16 percent two-aged harvest, and 8 percent uneven-aged harvest. The acres modeled for regeneration harvest under the No-Action Alternative vary somewhat from estimates in the current Forest Plan. The regeneration harvest acres in the current Forest Plan were based on FORPLAN model outputs, while the estimates used in this analysis are based on the SPECTRUM model. Changes were made in the assumptions used in the SPECTRUM model based on experience gained under the current Plan.

SPECTRUM models suitable land as either full, modified, or incidental timber yield (Table 3.13.10). For this analysis, lands identified by the model as full timber yield were categorized as likely to be prescribed for even-aged management. Lands identified as modified timber yield were categorized as likely to be prescribed as two-aged management or small patch cuts, while areas identified as incidental timber yield were categorized as likely to be prescribed as uneven-aged management, including openings less than 2 acres.

1 Acres modeled as Full Timber Yield by SPECTRUM.
2 Acres modeled as Modified Timber Yield by SPECTRUM, two-aged harvest or patch cuts.
3 Acres modeled as Incidental Timber Yield by SPECTRUM, uneven-aged harvest or openings less than 2 acres.
4 Natural regeneration refers to seedlings established from seeds falling to the ground from trees growing (or that grew) on the site. Artificial regeneration refers to planted seedlings.

Note: Acres harvested per year decreases with time as more young-growth reaches harvest age. Young-growth forest generally has lower defect rates and higher volume per acre.

Species composition. Of the four major commercial tree species on the Tongass, western hemlock is the most shade tolerant, followed by western redcedar, yellow-cedar, and Sitka spruce, in that order (USDA Forest Service 1990). Western hemlock is by far the most prevalent species, making up 83 percent of the old-growth forests (Farr and McClellan 1994). Dwarf mistletoe commonly infects western hemlock. Sitka spruce and yellow-cedar are rarely infected by dwarf mistletoe and western redcedar is not infected (Holsten et al. 2001). Having a diverse species mix contributes to wildlife habitat quality, species diversity, and minimizes losses due to insect and diseases that are species specific. In addition, Sitka spruce, yellow-cedar, and redcedar have higher economic values than western hemlock.

Regeneration harvest methods that create open conditions and expose bare mineral soil, such as clearcutting, encourage germination and growth of Sitka spruce (Ruth and Harris 1979). Group selection with openings of at least 2 acres, could also encourage germination and growth of Sitka spruce and the cedars, but may do so to a lesser degree than clearcutting due to side shading. The amount of sun reaching the surface would vary depending on the size, shape, and aspect of the opening. Regeneration methods that create less ground disturbance and smaller openings in the canopy such as single tree selection, smaller sized groups in group selection, overstory removals, and treatments with many reserve trees may encourage growth of western hemlock at the expense of less shade-tolerant species (Sitka spruce and yellow-cedar). However, limited retrospective studies indicate that Sitka spruce can be maintained in mixed hemlock-Sitka spruce stands over a wide range of cutting intensities if enough Sitka spruce trees are present in the stand after harvest (Deal and Tappeiner 2002, Deal et al 2002). Regeneration under two-aged systems would be similar to regeneration under even-aged harvest if leave trees are concentrated near the unit boundaries but may be more like uneven-aged harvest if reserve trees are scattered through the unit, due to shading from the residual overstory.

Alternatives 1, 2, and 3 are projected to have the least amount of two-aged and uneven-aged harvest (Table 3-13-9), followed by Alternatives 6 and 5, respectively. Alternatives 4 and 7 would have the most acres of two-aged and uneven-aged harvest. Alternatives that harvest fewer acres, especially Alternatives 1 and 2, would tend to maintain species composition across the Tongass similar to that found in the old-growth forests, because much less old-growth forest would be harvested. Forested areas in non-development LUDs normally subject to gap wind disturbance effects (refer to the *Forest Health* section) are likely to maintain the current species mix unless one of the predicted effects of climate change, an increase in catastrophic wind events, occurs. Juday et al. (1998) rated many potential impacts on the coastal forests of Southeast Alaska due to climate change. They concluded that there was a high risk of increased large scale blowdown across Southeast Alaska and an increased windthrow around harvest units. If this occurs, more area may come to resemble natural forests currently exposed to catastrophic winds. Alternatives with higher even-aged harvest, especially Alternatives 4 and 7, but also Alternatives 5 and 6, are more likely to create stand conditions that mimic catastrophic disturbance to some extent. However, these stands would lack the large amount of down wood found in natural stands created by catastrophic windstorms and many would be in areas that normally are subjected to gap disturbance.

Damage to residual trees. Western hemlock and Sitka spruce are thin-barked, shallow rooted species and are easily wounded during timber harvest activities (Harris and Farr 1974, USDA Forest Service 1983). These wounds provide an avenue for disease organisms to enter trees, causing rot and reducing their future economic value (Hennon and DeMars 1997). The size and shape of the opening affects the amount of damage. A retrospective study of 18 stands reported that overstory trees did have a greater incidence of wounding in stands that had been partial cut than in uncut stands and that the wounding increased with intensity of cutting; although, the study concludes that there was no significant increase in tree mortality, or in growth loss (Deal et al. 2002). McClellan (2005) reported that a recent operational-level study (part of the Alternatives to Clearcutting Study) found that there were increased problems during tree falling and yarding in group selection openings of less than 30 meters diameter (approximately 100 feet). Alternatives 1, 2, and 3 would have the least amount of two-aged and uneven-aged harvest, followed by Alternatives 6 and 5, respectively. Alternatives 4 and 7 would have the most acres of two-aged and uneven-aged harvest (Table 3.13-9).

Diseased trees may be more susceptible to windsnap and snow breakage (Nowacki and Kramer 1998), although one retrospective study found that many uprooted or broken-stemmed trees had died before falling (Hennon and McClellan 2003). In either case, the loss of residual trees that are left standing to provide structural diversity would result in management objectives not being met. The cedars are also susceptible to damage and subsequent attack by disease organisms. However, their wood appears to be more resistant to decay (USDA Forest Service 1990). Refer to the *Forest Health* section for a discussion of how the alternatives may affect dwarf mistletoe, insects, disease, and windthrow.

Growth rates. Estimation of future yields from young-growth stands created by timber harvest is critical for developing ASQs for the Forest Plan. Growth and yield tables have been developed for even-aged stands in Southeast Alaska (Taylor 1934, Farr 1984). Published growth and yield tables have not been developed for stands regenerated under two-aged or uneven-aged methods. Unpublished yield tables for these harvest types were developed by the Forest Service for use in estimating ASQ. These are part of the planning record.

Given that over 30 percent of the volume in old-growth stands is defective (Farr and Harris 1971), it is unlikely that these trees would respond to the additional growing space made available through partial harvest. While young western hemlock stands respond well to thinning, trees older than 100 years respond poorly to release (USDA Forest Service 1990). Information on growth rates for trees growing under a canopy in Southeast Alaska is limited. Western hemlock is shade tolerant and may grow well under partial shade. Sitka spruce is less shade tolerant than hemlock and it is reasonable to expect some growth loss when Sitka spruce is grown under residual overstory trees. However, Deal and Tappeiner (2002) reported that, in most cases, concerns about greatly reduced stand growth and vigor were unsubstantiated, based on a retrospective study of 18 stands in Southeast Alaska that had been partially cut 12 to 90 years earlier. Analysis of these stands did not detect significant changes in tree species composition, stand growth, hemlock dwarf mistletoe infection, or mortality rates (Deal et al. 2002).

One measure of future growth rates is the total amount of slow-growing old forest that would be harvested over the rotation. Alternative 7 would result in the most harvest, and the most even-aged harvest, followed by Alternatives 4, 5, 6, 3, 2, and 1, in that order. Alternative 7 would result in more than nine times the acres of old forest converted to productive young-growth stands as Alternative 1 (more than 807,000 compared to nearly 86,000 acres) and approximately 75 percent more than Alternative 5, No Action (more than 807,000 compared to nearly 464,000 acres).

Reforestation

The NFMA requires assurance that all areas receiving final removal harvest can be adequately restocked with trees within 5 years of that harvest. On the Tongass, natural restocking is usually adequate to meet this objective because both western hemlock and Sitka spruce are prolific seed producers (USDA Forest Service 1983). The new stand originates from advance regeneration and from seeds that come from residual trees or from trees adjacent to the harvest unit. Since 1988, natural regeneration has accounted for 94 percent of the reforestation program. The remaining 6 percent has been artificial regeneration (planting). The future need for planting would be determined on a site-specific basis to achieve management objectives such as increasing the abundance of Sitka spruce where western hemlock or brush may have a competitive edge or increasing the abundance of yellow-cedar or western redcedar, where natural regeneration of these species is anticipated to be inadequate. The desired species composition, required number of seedlings, and method of regeneration should be displayed in the silvicultural prescription. Table 3.13-9 lists the acreages that would require reforestation (natural or artificial) in the first and fifth decades by alternative.

Intermediate Treatment Methods

Intermediate treatments are any manipulation in a stand that occurs between two regeneration periods (Daniel et al. 1979). The regeneration period establishes the new stand, either through natural regeneration or through planting. Intermediate treatments are done to ensure that the new stand has the desired species composition, tree health, growth, and spacing, as well as to recover product value. They can also be used to create or improve habitat for wildlife. Intermediate treatments may be used if approved as part of a site-specific silvicultural prescription. Currently, the only intermediate treatment commonly used on the Tongass is pre-commercial thinning.

Precommercial thinning is applied in young stands that have not reached merchantable size. It is the most commonly applied intermediate treatment in Southeast Alaska. It is used to:

- Favor preferred tree species.
- Concentrate tree growth on fewer individuals to produce larger trees in a shorter period of time.
- Increase the amount of light reaching the forest floor, thereby retaining understory vegetation that is valuable wildlife forage (DellaSalla et al. 1994).

There are concerns over the effects of precommercial thinning on future wood quality, especially wider spacing of residual trees (McClellan 2005). Thinning can increase epicormic sprouting on the Sitka spruce trees (Deal et al. 2003). Lower density thinnings could increase taper and increase the size and longevity of lower branches, thus reducing future wood quality (McClellan 2005). Larger lower branches increase fluting in western hemlock, which reduces wood quality (Julin et al. 1993) (refer to the *Forest Health* section for a discussion of fluting).

Pruning removes the lower branches of a tree at an early age in order to produce knot-free wood. It is the only way to produce clear lumber in rotations less than 100 years (Daniel et al. 1979). However, pruning Sitka spruce trees can encourage epicormic sprouting in Sitka spruce and can limit diameter growth for all species. Deal et. al. (2003) found that the total number of sprouts was similar among different levels of pruning but significantly more large sprouts were produced when more of the crown was removed.

Commercial thinning is applied to young stands that have reached merchantable age. The primary difference between commercial and precommercial thinning is that the trees cut in a commercial thinning operation are removed and sold. Commercial thinning can be used to:

- Meet market demand for wood products, either from suitable or unsuitable lands (harvest would only be used on unsuitable lands to meet resource objectives, such as improving wildlife habitat, and where no irreversible damage would occur).
- Maintain or increase the growth rate of dominant and co-dominant trees by removing trees in the lower crown classes, increasing merchantable yields over the rotation.
- Stimulate development of more complex canopy structures or enhance forage in the understory in order to meet wildlife habitat needs.
- Improve scenic quality.

By maintaining or increasing growth rates, commercial thinning lengthens the time needed for a stand to reach CMAI, extending the rotation length (Daniel et al. 1979).

Precommercial thinning would be implemented under all alternatives based on funding. Pruning is likely to play a minor role in the foreseeable future under all alternatives. Commercial thinning is expected to play a larger role in meeting future demand under all alternatives over the next few decades, as areas harvested in earlier decades reach commercial size. Over the long term, alternatives with high harvest levels would create more stands, which in time would be available for commercial thinning. Also, alternatives that would facilitate creation of an integrated timber industry, especially Alternatives 4 and 7, are likely to lead to more commercial thinning because there would be a greater demand for smaller logs if, for example, a medium density fiberboard mill is built (refer to the *Economic and Social Environment* section for a discussion of the likely product mix under the proposed alternatives).

Allowable Sale Quantity

Allowable Sale Quantity and Timber Sale Program Quantity

The ASQ of each of the alternatives is an indicator of possible future timber supply level that each alternative could produce. ASQ is the maximum quantity of timber that may be scheduled for harvest from suitable lands on the entire Forest for the next 10 years (36 CFR 219.3). It is usually expressed as an annual average. The yearly quantity may exceed or be less than the annual average for the decade. The ASQ is a ceiling; it is not a future sale level projection or target and does not reflect all of the factors that may influence future sale levels.

The ASQ is an expression of the biological potential of the forest to produce timber within the constraints of other resource needs; it is constrained by harvest limitations necessary to meet LTSY requirements, multiple-use considerations, and environmental restrictions. Changes in the timber land base, timber inventory, or silvicultural prescriptions would affect ASQ. An ASQ is, to some extent, imprecise because it is based on estimating techniques (the SPECTRUM model) and Forest-wide data rather than on detailed, on-the-ground data from the timber sale area. Given the uncertainties inherent in developing an ASQ, shortfalls between the ASQ and timber sales are very possible.

The timber sale schedules for each Ranger District include that portion of the timber inventory that is scheduled for sale for a specific year. The schedule may include harvests from unsuitable lands and convertible products (such as beach log salvage and fuel wood) in addition to sales counting towards the ASQ. Schedules are updated annually or more frequently.

Table 3.13-11 displays the projected timber output for the first and fifth decades that could result from implementing each of the seven alternatives in both board feet and cubic feet. This output is composed of two categories: sawlogs and utility logs. The use and marketability of these log types is discussed in the *Economics and Social Environment* section. Alternatives with higher timber outputs may require a "ramp-up period"; therefore, ASQ is higher for these alternatives in later decades than in the first. Refer to the discussion in the *Economics and Social Environment* section.

Table 3.13-11
Allowable Sale Quantity (First Decade, Average Annual)

Alt	Sawlog (MMBF)[1]	Sawlog & Utility (MMBF)[1]	Sawlog (MMCF)[2]	Sawlog & Utility (MMCF)[2]

Factors Affecting the Allowable Sale Quantity

Within LUDs where timber harvest is compatible with the resource objectives of the area, there may be "intrusions," "physical factors," and "unmapped" standards and guidelines that limit timber management opportunities. These factors (discussed below), often termed "falldown," have been recognized at the forest level, and the anticipated timber output adjusted appropriately. These limitations may include lands that are not capable of supporting a sustained timber management program. In other cases, where there are physical limitations, a less intensive or perhaps unregulated output may be scheduled for this period. Other factors also contribute to differences between ASQs and timber sales, such as budgets and legal challenges.

The Forest-wide estimates used to develop the ASQ considered many of the factors contributing to differences between ASQs and the actual volumes produced in timber sales. These include factors affecting the suitability determination of forest lands that are usually encountered in on-the-ground examinations (e.g., sale reconnaissance, stand exams, layout, and sale preparation). For each alternative, areas were set aside (not scheduled for harvest) to allow for those factors most often encountered. Data from previous case studies, monitoring, site visits, inventory data, the GIS database, and the new Stand Density Model map were used to develop the acreage estimates (see Appendices A and B for more information).

More specifically, the following questions were considered:

1. Is it tentatively suitable? (36 CFR 219.14[a])

Appendix A of the proposed Forest Plan outlines the process used to determine the tentatively suitable land base. The three most common factors encountered during project implementation are: 1) unmapped streams that need buffers due to TTRA or Forest Plan standards and guidelines; 2) unmapped extreme hazard soils; and 3) forest land incorrectly mapped as capable of growing industrial wood products.

2. Is it appropriate for timber production? (36 CFR 219.14[c and d])

The Forest Plan standards and guidelines were reviewed for elements that are not mapped or in the GIS database and that could cause a loss of suitable acres. Eight factors were identified:

Land Selections – reduction due to the conveyance of selected lands to the State of Alaska and Native interests.

TTRA Stream Buffers – reduction due to unmapped Class I and II stream buffers (i.e., streams that were not mapped as Class I or II).

Non-Commercial Forest – reduction due to volume class mapping errors.

Slope/Soil Hazard – reduction due to unmapped steep slopes (i.e., areas with steep slopes or high hazard soils that could not be identified correctly by GIS mapping).

Cost Efficiency – excludes stands with the lowest economic potential from the suitable base.

Riparian Habitat (Class III streams) – reduction due to unmapped Class III stream buffers (i.e., Class III streams that could not be identified during mapping, usually due to canopy cover).

Karst/Caves – reduction due to upgrading of the karst classification to high vulnerability on some areas during field exams.

Remaining Standards and Guidelines – reduction due to unmapped raptor and murrelet nests, wolf dens, mountain goat habitat, and habitat linkages.

The sum of these subfactors produces the overall Model Implementation Reduction Factors (MIRF) for each category (geographical area, volstrata, operability class, alternative). The process and results are discussed in Appendix B. The average MIRF is 42 percent for the north districts, 17 percent for the central districts, and 23 percent for the southern districts.

Cost efficiency: TTRA provides that:

ANILCA is further amended by deleting section 705(d)(16 U.S.C. 539d(d)) in its entirety and inserting in lieu thereof:

> [d] All provisions of section 6(k) of the National Forest Management Act of 1976 (U.S.C. 1604[k]) shall apply to the Tongass National Forest

> except that the Secretary need not consider economic factors in the identification of lands not suited for timber production. (TTRA, Sec. 102.)

Economics is an important consideration in determining whether lands should be harvested; however, experience has proven that it is not feasible to effectively factor in economics as part of the suitability determination. Economic conditions fluctuate greatly during the course of a plan period. One year a certain area of land or species may be uneconomic to harvest, and another year market conditions may have changed to where the same area or species would be in demand. This makes it difficult to meaningfully assess the economics of harvesting a particular site over a 10-year period. Also, the value of the timber sale program must be considered as a whole rather than by only evaluating individual timber sales or harvest units in isolation, because some sales or units of low value are offset by other higher-value sales or units. The economics of harvesting any particular site can be considered as part of the project decision to approve harvest of the area.

Non-interchangeable components

The ASQ is partitioned into two portions, referred to as non-interchangeable components (NICs). The ASQ is partitioned to prevent overharvest of the best operable ground and to identify that portion of the timber supply that is more economic to harvest. The total ASQ is derived from the sum of the timber volumes from both NICs. For the Tongass, the following are identified as the NICs:

NIC I: Normal Operability (85 percent of the suitable land based on the LSTA). This is volume scheduled from suitable lands using existing logging systems. Most of these lands are expected to be economic under most market conditions. On average, sales from these lands have the highest probability of offering a reasonable opportunity for a purchaser to profit from his/her investment and labor. This is the best operable ground. The percent of volume from NIC I lands that contributes to ASQ varies from 87 to 99 percent, depending on the alternative (Table 3.13-12).

Normal operability includes those systems most frequently used on the Tongass. These systems are tractor, shovel, standard cable, and helicopter yarding up to a distance of 0.75 mile.

NIC II: Difficult and Isolated Operability (15 percent of the suitable land based on the LSTA). This is volume scheduled from suitable lands that are available for harvest using systems not in common use in Southeast Alaska. Most of these lands are presently considered economically and technologically marginal. The percent of volume from NIC II lands that contributes to ASQ varies from 1 to 13 percent, depending on the alternative (Table 3.13-12).

Difficult operability includes those systems used on the Tongass that have significantly higher costs. These may include long-span skyline, multi-span, or helicopter with yarding distances greater than 0.75 mile. This category also includes lands that have limited access as a result of being isolated by prior harvest activities or other management activities.

Isolated operability refers to small stands of isolated timber that are extremely difficult to harvest. The harvest system could vary, but would be more costly due to the location of the stand, with average yarding distances greater than 2 miles.

Table 3.13-12
Estimated Harvest by Operability Class (NIC I and NIC II) in the First Decade (MMBF[1] and percent)

Alternative	NIC I		NIC II		Total
1	48.8	99%	0.6	1%	49.3
2	143.5	95%	7.6	5%	151.1
3	185.5	91%	18.5	9%	204.0
4	271.8	87%	39.8	13%	311.5
5	238.5	89%	28.5	11%	267.0
6	237.7	89%	29.3	11%	267.0
7	366.5	87%	54.5	13%	421.0

[1] MMBF: million board feet
Source: SPECTRUM model. Numbers may not appear to add correctly due to rounding.

Harvest during the first few decades would come primarily for old-growth forests within NIC I areas. Harvest in the later decades would come, almost entirely, from mature young-growth forests (also in NIC I areas), which are expected to have less defect and, therefore, higher volumes per acre.

Other Factors that Affect the Timber Sale Program

Other factors that may affect the amount of timber actually sold include the cost of preparing a timber sale, administrative appeals and lawsuits (which may delay or forestall sales), transportation and fuel costs (which affect the cost of harvesting a sale, especially a helicopter sale), and market conditions that may discourage purchasers from bidding on sales. Additional harvest may occur on lands that are not suitable for timber management, for example, to stimulate development of more complex canopy structures or to enhance forage in the understory in order to meet wildlife habitat needs. This would only occur if it is determined that there would be no irreversible damage to resources. Another example would be incidental harvest on steep slopes. These types of harvest would not contribute to ASQ, but would add to the total timber harvest on the Forest.

Allowable Sale Quantity and Long-term Sustained Yield Capacity

LTSY is the maximum timber yield that can be sustained indefinitely from lands managed for timber production when all stands have been converted to a managed state. This varies by alternative, depending on the amount of suitable land and on standards and guidelines particular to each alternative. LTSY is a function of the total number of acres allocated to timber management, the management intensity, standards and guidelines, silvicultural systems, and the productive capacity (conifer growth) of the suitable lands. The harvest schedule is based on: 1) a harvest schedule that exhibits non-declining yield at or below LTSY capacity, 2) a regeneration harvest age at or beyond culmination (maximum) of Mean Annual Increment, and 3) a planning horizon of 150 years.

The projected yield over the next 15 decades that could contribute to the ASQ is expected to increase over time as second-growth forests mature and become available for harvest. The average volume per acre of old-growth forest is approximately 29 MBF per acre. The expected volume of 100-year-old stands of second growth in the central portion of the Tongass is approximately 56 to 60 MBF per acre (based on the Forest's managed yield tables for this area), depending on stand management (see below). As more 100-year-old stands become available for harvest, the ASQ could increase, or the land base needed to produce a given ASQ could decrease. In addition, commercial thinning would add to harvest volume.

The ASQ does not exceed the LTSY during the 100-year-plus planning horizon. The potential ASQ is expected to be between 49 and 92 percent of LTSY for the rotation under all alternatives based on the LTSY calculations. Table 3.13-13 displays the ASQ and LTSY by alternative. For all alternatives, the ASQ never exceeds the LTSY during the planning horizon. Alternatives that would allocate a greater number of acres for timber management and/or have more acres under intensive management would produce the highest LTSYs.

Table 3.13-13
Allowable Sale Quantity and Long-term Sustained Yield Capacity (MMBF[1])

Alt.	Decades 1 to 5 Average Annual	Decades 6 to 10 Average Annual	Decades 11 to 15 Average Annual	LTSY (MMCF)[2]	Maximum Percent of LTSY
1	49.3	49.8	52.0	21.5	49
2	152.6	153.6	153.8	48.3	69
3	204.5	204.6	204.7	59.9	76
4	350.3	360.0	360.0	92.4	88
5	267.0	267.0	267.0	68.4	87
6	267.0	267.0	267.0	72.9	82
7	421.0	421.0	421.0	102.5	92

[1] MMBF: million board feet
[2] MMCF: million cubic feet. SPECTRUM only expresses long-term sustained yield in the cubic foot measure. Direct conversion from MBF to MCF is complex, varying by tree size and taper but is approximately 5 MBF to 1 MCF

Future Conditions

Approximately 90 percent of the existing timber stands on the Tongass are beyond CMAI. Timber stands that exceed CMAI are either in decline or are not growing at optimal rates for their site's potential productivity. The western hemlock-Sitka spruce forest type is one of the world's most productive forest types (USDA Forest Service 1983); it is capable of producing prodigious amounts of wood. The updated forest yield tables for the central part of the Tongass estimate that a normally stocked stand 40 years old would contain 7 MBF of merchantable wood per acre. By age 70, volume should increase to 29 MBF of wood per acre, assuming no precommercial thinning occurred. The age of CMAI would be around 100 years with a merchantable volume of 56 MBF per acre, assuming no precommercial or commercial thinning. If the same stand is thinned, volume at CMAI is estimated to be 60 MBF, in addition to an estimated 8 MBF of commercial thinning volume obtained at age 60. Yields from uneven-aged silvicultural systems would be considerably less, approximately 28 MBF at age 200, based on the updated forest yield tables.

As a greater proportion of the Forest is converted from slower growing, highly-defective stands to stands well-stocked with vigorously growing conifers, total forest growth would increase. Because of higher volumes and lower defect, managed young-growth would be able to provide higher harvests on the same land base or support the same harvest on a smaller land base. Under a 100-year rotation, between one-forth and one-third of the suitable land would not be needed to provide a given ASQ, depending on alternative. This portion of the timber base could revert to some other land use and be available to provide old-growth habitat, or the ASQ could be increased if market conditions allowed.

Only a portion of the Forest would emphasize timber management; most of the existing mature and old-growth stands on the Forest would be maintained. Various amounts of old-growth conifer stands would be maintained or allowed to develop under each alternative. Alternatives that allocate the most acres to development-oriented land allocations would gradually have more stands in younger timber age classes, and fewer stands of old growth. However, more than 150 years from now, the predominant age class on the Tongass would still be greater than 150 years

(Table 3.13-14). The percent of total productive forest land that would be managed stands of less than 150 years of age is expected to be a relatively small component of the forest landscape on a Forest-wide basis for all alternatives. Old growth would still be the predominant vegetative structure on the Tongass (Table 3.13-15).

Conifer growth in young stands can be accelerated through silvicultural treatments to control conifer stocking. Benefits from such treatments may include larger piece size and consequently lower logging costs, increased stand variability, higher quality wood, and employment opportunities. In addition, treatments may shorten the time period spent in the stem exclusion phase of stand development and offer other resource benefits.

Managing stands to enhance wildlife and fish habitat carrying capacity is one of the objectives of the Tongass National Forest. To help meet this objective, the Forest Service has implemented studies on stand management, including TWYGS, the Alternatives to Clearcutting study, and other Pacific Northwest research, some of which has been discussed in this section. Appendix B of the Forest Plan includes a list of information needs.

Cumulative Effects

Cumulative effects to timber include past and present and proposed harvest discussed above. Table 3.13-13 presents a comparison of harvest and LTSY by alternative, an important measure of the cumulative effect on the growing stock on NFS land. Maximum harvest levels on NFS lands proposed under all alternatives are well within the LTSY. Table 3.13-14 displays the age class of forests on NFS lands by decade for the next 160+ years; Table 3.13-15 displays the projected stand structure over the same period. Cumulative effects on timber resources across Southeast Alaska are presented below.

In 1954, there were approximately 6.5 million acres of productive forest land on all ownerships in Southeast Alaska. The amount of forest land in Southeast Alaska that is available for timber management has declined over the past century, largely due to Wilderness and LUD II designation by Congress and to land allocated to non-development LUDs in the current Forest Plan. This, along with mill closures and changes in timber markets, has contributed to a decline in timber harvest. Harvest on all lands in Southeast Alaska peaked in the 1980s and has been in decline since then. Total harvest on federal, state, and private lands declined from just under 1,000 MMBF in 1989 to less than 200 MMBF in 2005. Approximately 767,000 acres of productive forest land have been harvested since 1954 in Southeast Alaska, approximately 59 percent of this is NFS land and 41 percent is on state, Native corporation, and other private lands.

Currently, there are more than 0.75 million acres of NFS lands considered suitable for timber management on the Tongass. In addition, nearly 0.75 million acres of state, Native corporation, and other private lands are available for harvest. The maximum annual harvest from the Tongass National Forest is 267 MMBF under the current Forest Plan, although actual harvests have averaged near 50 MMBF per year for the last few years. Potential annual harvest on state and private land has been estimated to be approximately 109 MMBF (Brackley et al. 2006a); although, comments from Sealaska Corporation indicate it may be much lower. Based on past experience, most of the harvest on private land would be exported and would not contribute to meeting local demand. Using this estimate, cumulative harvest in Southeast Alaska would range from as low as 158 MMBF under Alternative 1 to approximately 530 MMBF under Alternative 7. Table 3.13-16 displays the cumulative harvest under the proposed alternatives.

Table 3.13-16
Maximum Estimated Annual Timber Harvest in Southeast Alaska during the First Decade (MMBF)

Alternative	National Forest[1]	State and Private[2]	Total
1	49	109	158
2	151	109	260
3	204	109	313
4	312	109	421
5	267	109	376
6	267	109	376
7	421	109	530

[1] SPECTRUM model estimates, 2007
[2] 102 MMBF/year from Native corporation lands and 7 MMBF/year from state land (Brackley et al. 2006a). Most harvest on private land is exported.
MMBF: million board feet.

There are several risk factors and uncertainties that may affect timber outputs; these include the reliability of existing information of forest stands, accessibility, economics, budget, harvest on private land, development of new markets, investments in new processing facilities, and climate change.

The recent LSTA indicates that approximately 85 percent of the suitable timber land would be accessible using normal harvest methods, just under 10 percent would be difficult, and just under 6 percent would be isolated. When economic and environmental risk factors are considered, additional areas are likely to be identified as difficult or isolated during project planning. Risk factors assigned by the LSTA team and district personnel indicate that about 85 percent of the suitable acres with old-growth forest would be in the normal category. However, until field work is completed, actual conditions remain uncertain and there is a risk that some areas considered suitable for timber management are actually unsuitable and that areas considered to be accessible using normal harvest methods will prove to be difficult or isolated. Increasing fuel costs may restrict the use of helicopters, which would mean some areas with suitable timber would be too expensive to harvest. Similarly, increases in road construction costs may affect the economic viability of some sales. In addition, funding levels for preparing timber sales are uncertain they depend on the amount Congress chooses to allocate in any given year.

The harvest levels associated with the alternatives discussed above, especially Alternatives 4, 5, 6, and 7, depend on developing new processing facilities and/or new markets. If these are not developed, harvest levels may not increase much beyond current levels. Also, total harvest projections for Southeast Alaska depend, in part, on how much timber is harvested from state and private lands. The estimates used in this analysis are derived from published reports. However, comments received following publication of the DEIS indicate that actual harvest levels, especially on Sealaska land, may be lower than those estimates. Sealaska indicates that, without the land adjustments they propose, they will be unable to continue to harvest at current levels. Conversely, if suitable land is transferred to Sealaska in exchange for lands that, while valuable for wildlife habitat or recreation, are not suitable for timber production, harvests on NFS lands will likely need to be reduced.

Timber harvest programs under any of the proposed alternatives, as well as on state and private land may be affected by factors related to climate change. Juday et al. (1998) rated many potential impacts on the coastal forests of Southeast Alaska due to climate change. They concluded that there was a high risk of increased large scale blowdown across Southeast Alaska, increased windthrow around harvest units, increased damage from black-headed budworm outbreaks and other insects, and increased risk that new fungal tree diseases will appear in Southeast Alaska. These factors, if they occur, could alter harvest and growth projections outlined in this analysis, as well as have a major affect on wildlife habitat. In contrast, Juday et al. also concluded that there was some likelihood of increased tree growth and increased site productivity; previously non-commercial forest could become commercial forest. Refer to the *Forest Health* and the *Climate and Air* sections for additional information.

Minerals

Affected Environment

A wide variety of mineral deposit types and mineral resources occur within the boundaries of the Tongass National Forest, including gold, silver, molybdenum, and uranium, and nationally designated "strategic" and "critical" minerals such as lead, zinc, copper, tungsten, and platinum group metals. The Forest Service recognizes that minerals are fundamental to the Nation's well being and, as policy, encourages the exploration and development of the mineral resources it manages. The Secretary of Agriculture has provided regulations (36 Code of Federal Regulations [CFR] 228) to ensure surface resource protection, while encouraging the orderly development of mineral resources on National Forest System (NFS) lands.

Southeast Alaska has a long history of mineral prospecting and mining. The first mineral location in Southeast Alaska was recorded in 1867 by a Russian trader near New Kasaan on Prince of Wales Island. In 1880, gold was discovered in placer gravels near Juneau. This discovery sparked keen interest and, by the turn of the century, dozens of mines were in production from the Juneau Mining District to the Ketchikan Mining District. Mining remained active until World War II. From the close of World War II to the mid-1970s, mineral exploration and production in Southeast Alaska remained low compared to the activity documented at the beginning of the century. Prospecting and exploration generally increased during the mid-1970s, in part due to the Quartz Hill and Greens Creek discoveries, improved metal prices, technological advances, and the deregulation of gold. Metal prices have maintained generally favorable trends since the mid-1980s, resulting in increased exploration and renewed interest in precious metals, mainly gold.

With respect to National Forest management, mineral resources are legally divided into three groups: locatable minerals, leasable minerals, and salable minerals. The authority of the Forest Service to influence and regulate the exploration, development, and production phases of mining operations varies with each group. As a result, the Forest Service manages mineral resource programs that are specific to each group of minerals.

Locatable Minerals

A locatable mineral is any mineral that is "valuable" in the usual economic sense, or has a property that gives it distinct and special value. These are typically what are known as "hardrock" minerals. Locatable minerals may be recovered from load deposits (solid rock) or placer (surficial) deposits. Examples of some locatable minerals on the Tongass National Forest are gold, silver, copper, molybdenum, iron, nickel, lead, and zinc.

The General Mining Law of 1872, as amended, grants every United States citizen the right to prospect and explore public domain lands open to mineral entry. The right of access is guaranteed and is not at the discretion of the Forest Service. Upon discovering a valuable mineral deposit, citizens have the right to locate a mining claim and remove the mineral resources. The citizen holding a mining claim is called the claimant. The claimant is responsible for initiating mining activities and investing the capital required to conduct mineral exploration, site development, mine operation, and reclamation of the site.

The Forest Service works with mining claimants to provide reasonable access to their claims, minimize adverse environmental impacts on surface resources, and ensure reasonable reclamation of disturbed lands affected by mining operations. Protection of surface resources is accomplished by reviewing the mining plan of operations submitted by the claimant, disclosing impacts of the proposed mining operations in a site-specific environmental document, approving only those activities that are reasonably necessary for the proposed operation, monitoring operations to ensure environmental standards are met, and ensuring prompt and reasonable reclamation of disturbed areas.

By law, designated Wilderness, National Monuments, Research Natural Areas, Enacted Municipal Watersheds, and Wild Rivers (when designated by Congress) are withdrawn from mining claim location. These withdrawn areas are, however, subject to mining claims with valid existing rights established before the date the areas were withdrawn from mineral entry. As a consequence, some mining claims located within existing or proposed withdrawn areas could be developed in the future.

On the Tongass, the Primitive Recreation, Semi-Remote Recreation, Old-Growth Habitat, Experimental Forest, Special Interest Areas, Scenic Rivers, and LUD II Land Use Designations (LUDs) remain open to mining activities. Special stipulations and more stringent mitigation measures are required for mining activities in these LUDs; therefore, there is a higher cost to develop minerals in these LUDs. Modified Landscape, Scenic Viewshed, Recreational Rivers, Timber Production, and Minerals LUDs remain open to mineral activities and do not require special stipulations or more stringent mitigation measures; therefore, mineral development in these LUDs would be at an average cost.

Leasable Minerals

Certain types of minerals, primarily energy resources, are not subject to mining claim location, but are available for exploration and development under provisions of the Mineral Leasing Act of 1920. Access to these types of minerals is provided through leases, permits, or licenses that include fee and/or royalty payment conditions. Federally owned leasable minerals include oil, gas, coal, geothermal resources, potassium, sodium, phosphates, and sulfur. The authority to manage these minerals is presently administered by the U.S. Department of Interior, Bureau of Land Management (BLM) in cooperation with the Forest Service.

No leasable minerals are presently being produced on the Tongass National Forest, and the anticipated demand is expected to remain low. BLM recently conducted an assessment of mineral resource potential in support of a resource management plan for the Ring of Fire planning area (BLM 2006), which includes Southeast Alaska. The assessment indicated the potential for oil and gas occurrence in the Yakutat region was considered to be high, based on geologic factors (URS Corporation 2006). While there has been exploration activity in the Yakutat area in the relatively recent past, the resource development potential is considered low; therefore, BLM expects no exploration or development activity within the next 10 to 15 years. Outside of the Yakutat area, oil and gas occurrence potential elsewhere in the Tongass is considered low to none.

Occurrences of coal found at several locations in Southeast Alaska has prompted the identification of the Angoon, Admiralty, and Kuiu coal districts; the coals in the two former districts are classified as bituminous, while the Kuiu deposits are ligmite (URS Corporation 2006). Several small mines on Admiralty Island produced coal during the late 1800s and early 1900s. Lignite deposits also occur at several other locations in Southeast Alaska, although they are of small extent. Similarly, the occurrence potential for coalbed natural gas (coalbed methane) is considered high for the Admiralty and Kuiu Islands coal deposits and the Yakutat area. BLM considers development of these resources to be uneconomic over the next 10 to 15 years, other than possibly for local use, and does not foresee associated exploration or development activity.

Geothermal resources occur in 19 known locations in Southeast Alaska. Thermal springs in several locations have been developed for small-scale commercial uses such as tourism, aquaculture, community bathhouses, and district heating of buildings (URS Corporation 2006). There has been some recent interest in geothermal resources in the Bell Island area, but BLM has undertaken no leasing activity to date. While the occurrence potential for geothermal resources is considered high in several locations and some exploration could occur, BLM does not anticipate geothermal development activity over the next 10 to 15 years.

Salable Minerals

Salable, or “common variety,” minerals on NFS lands are sold rather than located or leased. These minerals include petrified wood and common varieties of sand, rock, building stone, gravel, pumice, clay, and other similar materials. Such common variety mineral materials include deposits that, although they have economic value, tend to be relatively widely available and used close to the source of production. These minerals are most commonly used as building materials and are also used for agriculture, cleaners and abrasives, and as inputs to manufacturing processes.

The predominant salable commodity extracted on the Tongass National Forest is crushed rock used to construct roads. The supply of quality rock sources is largely dependent upon the locations of active logging operations. Presently, there is an adequate supply of rock sources with suitable quality (hardness and durability) in the southern third of the Tongass. However, rock quality is poor in the northern two-thirds of the Forest, and good material sources are difficult to locate in current timber production areas. Sand and gravel sources are scarce throughout the Forest, except within the Yakutat Ranger District.

All roads built in the Tongass require rock for construction because the subgrade soils have poor strength characteristics. The demand for crushed rock will closely follow the need to construct new timber sale roads. The total in-service use of rock for existing roads was 43,962,500 cubic yards, which was used to construct 3,355 miles of road. As the use of forest roads increases, and both the Alaska State Department of Transportation and the Federal Highway Administration assume responsibility for maintenance of some roads, the demand for crushed rock will increase. It will be expensive to locate mining sites with suitable quality and quantity in the northern part of the Forest, and haul distances will increase. Outside NFS lands, new and existing communities will require mineral materials for development of roads and for foundations for homes, schools, and other buildings. The demand for rock from public land in support of these growing communities is likely to increase.

Limestone and marble are abundant in Southeast Alaska, and both have historically been produced from quarries in the region for use as building stone (BLM 2006). Identified marble resources in the region are estimated at over 800 million tons. Large quantities of limestone have been quarried from Prince of Wales and Dall Islands. Continued exploitation of these building material resources could be expected in the future. While several areas in Southeast Alaska also have geologic formations that are favorable for the occurrence of pumice deposits, market and location conditions indicate there will be little or no foreseeable development potential for pumice (URS Corporation 2006).

Mineral Resource Inventory and Development Potential

Most estimates of locatable mineral resource potential use a format developed by the U.S. Bureau of Mines and the U.S. Geological Survey (U.S. Bureau of Mines and U.S. Geologic Survey 1980, as cited in USDA Forest Service 1997a). The U.S. Bureau of Mines was abolished in 1996. Mineral resources are divided into "identified resources" and "undiscovered resources." The Tongass contains both identified and undiscovered reserves.

Identified Mineral Resources

The identified mineral resources on the Tongass were described by the U.S. Bureau of Mines, Alaska Field Operations Center, in An Economic Analysis, Tongass Land Management Plan, Mineral Resource Inventory (Coldwell 1990). For summaries of this report, see the 1991 Forest Plan Revision Supplement to the Draft EIS and the 1997 Forest Plan Revision Final EIS (USDA Forest Service 1991, 1997a).

The methods used by the U.S. Bureau of Mines included the steps discussed below. First, a mineral resource inventory was compiled from all available sources, resulting in the identification of 148 locatable mineral deposit areas within the Tongass National Forest. These 148 deposits were assigned to a mineral deposit model (Berg 1984). Tonnage and grade were determined for each based on published information, or were calculated using models developed by Cox and Singer (1986). The gross metal value for each deposit area was calculated by combining the tonnage and grade figures with an average price from 1978 to 1987 for each commodity. Each deposit area was evaluated to determine its pretax net present value.

Next, the 148 deposit areas were grouped into 52 identified mineral activity tracts that had high mineral development potential (MDP). These 52 tracts were further ranked from 1 to 3, based on the likelihood of exploration and development activity within the next 10 to 15 years. Areas assigned a ranking of 1 have the highest potential for development. Rank 1 areas contained at least one deposit with a positive after-tax net present value (at a 4 percent discounted cash flow rate of return) and/or at least one active gold deposit (site of current industry activity). Rank 2 areas contained at least one deposit with a positive pre-tax net present value (at a zero percent discount rate) and/or at least one "critical" and "strategic" mineral deposit with a vulnerable supply source. Rank 3 areas do not meet these criteria; their lower rankings may be due to a lesser likelihood of mineral occurrence, or because of a lack of available information.

Of the 52 tracts, 22 are categorized as Rank 1, 7 are categorized as Rank 2, and 23 are categorized as Rank 3. The tracts are listed in Table 3.14-1. The gross metal value of the identified mineral resources within the boundaries of the Tongass was estimated at $37.1 billion (expressed as 1988 dollars) in the U.S. Bureau of Mines study (Caldwell 1990). Highest among the individual minerals were molybdenum ($14.4 billion) and iron ($12.7 billion), with gold third at $2.26 billion.

The Coldwell (1990) report is the most recent comprehensive study of mineral resources for the entire Tongass. Additional studies of mineral resources in the Tongass have since been conducted, however. These include Mineral Investigations in the Ketchikan Mining District, Southeastern Alaska (Maas et al. 1995); Mineral Resources of the Chichagof and Baranof Islands Area, Southeast Alaska (Bittenbender et al. 1999); and Mineral Assessment of the Stikine Area, Central Southeast Alaska (Still et al. 2002). These studies conducted further investigations on known mineral deposit areas (KMDAs) within the Tongass. These

Notes: Critical minerals are those minerals necessary to supply military, industrial, and essential civilian needs during a national defense emergency, and not found or produced in sufficient quantities to meet emergency needs (as defined in the Strategic and Critical Materials Stock Piling Act of 1979). Examples of critical minerals include lead, zinc, copper, tungsten, and the platinum group metals.
Reference 1: Coldwell 1990; Reference 2: Maas et al. 1995; Reference 3: Bittenberger et al. 1999; Reference 4: Still et al. 2002
L=low; M=medium; H=high; MDP=mineral development potential; MEP=mineral exploration potential

KMDAs included the original tracts studied by Coldwell (1990). Each study reported estimates of MDP as low, medium, and high for each KMDA, as well as for individual mines, prospects, and occurrences. The designations given in Table 3.14-1 for these reports are for the highest rating given for any prospect studied in that tract.

The 1995, 1999, and 2002 area studies give essentially identical definitions for the following MDP designations:

> High—High grades and probable continuity of mineralized rock exist. The property is likely to have economically mineable resources under current economic conditions. A high potential exists for developing tonnage or volume with reasonable geologic support for continuity of grade.
>
> Medium—Either a high grade or continuity of mineralization exist. Mineralization is confined by geology, structures, and/or grades are overall low. It could serve as a material source if economics were not a factor, but is presently uneconomic at existing conditions.
>
> Low—The property exhibits uneconomic grades and/or little evidence of continuity of mineralized rock. There is little or no obvious potential for developing resources or is an insignificant source of the material of interest.

Differences in MDP designations between these area studies and Coldwell (1990) reflect additional geologic and chemical data, changes in prices, and cost and likelihood of development based in part on LUDs at the time of the study. In addition, Still et al. (2002) ranked each mine prospect and occurrence by mineral exploration potential (MEP). The MEP ranking takes into account the potential for extent of mineralized rock but not current land status of the site. The highest MDP and MEP rankings for each area are summarized in Table 3.14-1.

Undiscovered Mineral Resources

The methods used by the U.S. Geological Survey, Branch of Alaskan Geology to identify "undiscovered" locatable mineral resources are detailed in their report, Undiscovered Locatable Mineral Resources of the Tongass National Forest and Adjacent Lands, Southeastern Alaska (Brew et al. 1991). Their work involved the definition of areas or "tracts" that may permit the occurrence of one or more deposit types; the estimation of the numbers of undiscovered deposits of each type in each tract, along with the expected tonnage and grade of each type; and the use of computer simulation using these estimates to produce a probability distribution of the quantities of metal contained in the tract. This resulted in the preparation of location maps along with descriptions of 930 metal-bearing localities. The 930 metal-bearing localities were grouped into four classes, based on the estimated value of undiscovered mineral resources per acre: Class 1 has a relatively high mineral value per acre, Class 2 has a moderate mineral value per acre, Class 3 has a relatively low mineral value per acre, and Class 4 has nominal mineral value per acre.

Each tract is considered likely to contain one or more different types of mineral deposits. The estimation of the number of deposits of a given type in a tract is the single most-critical step in probabilistic mineral resource assessment. It requires re-evaluating all of the factors used in initially defining the tract, together with three additional factors: thoroughness of exploration (tracts already thoroughly explored are less likely to contain undiscovered deposits), size of tracts (smaller tracts are likely to contain fewer undiscovered deposits), and physical dimensions of deposit types (different types of deposits occupy different volumes of rocks).

The U.S. Geologic Survey study (Brew et al. 1991) included estimation of the gross metal value of undiscovered mineral resources for the Tongass National Forest. In 1990, this value was $28.3 billion (expressed as 1988 dollars). Highest among the individual minerals were copper ($6.8 billion), iron ($4.6 billion), molybdenum ($4.35 billion), and tin ($3.4 billion). These totals cover the entire Tongass National Forest, and thus include areas currently withdrawn from mineral activity.

Mineral Resource Demand

The extent to which identified and undiscovered mineral resources on the Tongass will be exploited in the future will depend largely upon the level of demand for those resources. Demand for mineral resources can be inferred based on the amount of money spent by the mining industry to prospect and explore for mineral resources in Southeast Alaska. Increases in the amount of money spent on exploration reflect an increase in demand for mineral resources. Between 1982 and 1987, the mineral industry spent an average of $2.92 million per year on mineral exploration in Southeast Alaska, with a high of $5.85 million in 1987 (USDA Forest Service 1997a). Exploration expenditures increased drastically for the 1988 to 1991 period, when the industry spent more than $20 million each year. Expenditures generally declined for the next 10 years, reaching $1.6 million in 2001, before increasing again to a level of $9.4 million in 2005 (Alaska Department of Natural Resources [ADNR], Alaska's Mineral Industry annual reports and summaries for 1997 to 2005).

Demand for mineral resources can also be inferred by modeling the economic viability of identified mineral resources. Identified mineral resources with high degrees of economic viability will reflect an increase in mineral-related activities or in demand for those resources by industry. The economic viability of 148 mineral deposits located within the Tongass National Forest were modeled by the U.S. Bureau of Mines (Coldwell 1990), as discussed previously. Based on economic criteria or the presence of an active gold deposit, 22 of 52 mineral activity tracts were identified as most likely to be developed (Rank = 1), and 10 were identified as likely to provide a positive rate of return when cash flow was discounted at zero percent.

Mineral Production

Mineral production in Southeast Alaska in recent years has been dominated by the Greens Creek Mine at the north end of Admiralty Island. Greens Creek is an underground mining operation that opened in 1989 and produces silver, zinc, lead, and gold. The mine processed nearly 806,000 tons of ore in 2004 and provided 265 full-time jobs (ADNR 2005). Other Southeast Alaska mining activity in 2004 was comprised of at least 18 different rock, sand, and/or gravel operations. These mines produced a total of nearly 3 million tons of material during the year and supported 83 employees. The Forest Service approved a Plan of Operations for the Kensington Gold Mine north of Juneau in 2005, and Coeur Alaska, Inc. subsequently began construction activities on the site. However, a lawsuit was filed against the U.S. Army Corps of Engineers and the Forest Service, challenging the permitted tailings disposal facility, citing violations to the Clean Water Act. The plaintiffs failed in District Court but were upheld on appeal by the 9th Circuit Court in 2007. The Forest Service anticipates the submittal of a revised Plan of Operations in 2008.

Tongass Land Management for Minerals

As described previously, the Forest Service administers mineral exploration, development, and production activities through the legal/regulatory systems for locatable, leasable, and salable minerals. The Forest Service also accounts for mineral resources in the land management planning process. One way of recognizing the importance and potential of mineral resources is through the designation of Minerals LUDs in the Forest-wide land allocation. The intent of the Minerals LUD designation is to encourage exploration and development of locatable minerals in areas of high mineral potential, while taking other resource values into account. The Tongass Forest Plan includes management prescriptions for those areas, and standards and guidelines specific to minerals and geology.

The current Tongass Forest Plan, as amended, allocates 13 areas of the Forest to the Minerals LUD. These areas total 170,514 acres and are widely distributed across most portions of the Tongass. Several Minerals LUDs are clustered around Juneau and Lynn Canal, and there is another cluster near Clarence Strait and the southern part of Prince of Wales Island.

Unlike other LUDs, the Minerals LUD is an “overlay” designation that applies management prescriptions for minerals to the affected area, in addition to the prescriptions of the underlying LUD. For example, a Minerals LUD in the northern part of Admiralty Island, northeast of the Greens Creek mining area, overlies part of the Young Bay Experimental Forest LUD. The Minerals LUD and Experimental Forest management prescriptions both apply in this area, with the Minerals LUD having priority.

Environmental Consequences

Trend in expenditures for mineral prospecting and exploration, the demand for access to National Forest lands for the purpose of mineral exploration, and development is expected to increase over the next 10 years. Mineral entrants will continue to submit plans of operation to the Forest Service for approval, and regulations under which those operating plans are processed will not change by alternative. Identified and undiscovered mineral resource tracts, characteristics and location of mineral deposits, and Southeast Alaska geology will not vary as a result of implementing any of the alternatives.

Direct and Indirect Effects

Locatable Minerals

Under any alternative, future exploration and development (except for valid, currently existing rights) would be precluded in areas withdrawn from mineral entry, such as Wilderness. The availability of mineral resources of the Tongass National Forest may also be affected by the allocation of other LUDs in each alternative, and the use of Forest-wide standards and guidelines during project implementation. The standards and guidelines of certain LUDs could affect the cost of conducting exploration, development, and reclamation activities, and thus influence the exploration of some areas for their mineral resources.

Most withdrawn lands are designated so by the U.S. Congress (i.e., wilderness withdrawals). On other NFS lands, the Forest Service does not have the authority to approve or disapprove most mineral operations (the exception being salable minerals), but can impose stipulations on how mineral resources are developed in order to protect surface resources. Thus, the potential effects of alternatives on mineral resources can be estimated by analyzing the relative degree to which LUDs and their associated prescriptions could economically constrain proposed mineral activities.

For this purpose, three categories of LUDs are identified: withdrawn areas (which assume higher costs for the development of valid existing rights), and two “open” categories; one with average costs and one with higher-than-average costs. Table 3.14-2 shows the LUDs corresponding to each category.

Wilderness, National Monument, and LUD II acres remain the same for all Forest Plan alternatives, as do existing withdrawals within the Research Natural Area, Enacted Municipal Watershed, and Wild, Scenic, and Recreational River designations. Open areas with higher costs generally correspond to non-withdrawn areas in the Mostly Natural Setting LUD group, while open areas with average costs correspond to those areas within the moderate and intensive development LUD groups. Alternative 5 (No Action) retains the existing acreage in Experimental Forest and Special Interest Area designations, while all of the other alternatives would increase the acreage in these LUDs. In addition, all alternatives except Alternative 5 would add or expand three Minerals LUD overlays; one new area north of Hyder, an

Table 3.14-2
Economic Availability of Minerals Relative to Land Use Designations

Mineral Availability	LUDs
Withdrawn – Existing *(Areas remain open to mineral rights established prior to the area being withdrawn)*	Wilderness National Monument Research Natural Area Municipal Watershed Wild River
Open Areas – High Cost *(Mineral exploration and development requires special stipulations and more stringent mitigation measures)*	Remote Recreation Semi-Remote Recreation Old-Growth Habitat LUD II Experimental Forest Special Interest Area Scenic River Minerals LUD Overlay on Withdrawn Areas (prior rights only)
Open Area – Average Cost	Recreational River Scenic Viewshed Modified Landscape Timber Production Minerals LUD Overlay on All Open Area LUDs

expansion of the area near Niblack (on the north side of Moira Sound) on south Prince of Wales Island, and a new area north and south of the West Arm Cholmondeley Sound on south Prince of Wales Island. The Minerals LUD overlay may have the effect of changing the exploration and development costs from high to moderate, depending on the basic LUD of the area.

Locatable minerals are divided into identified resources and undiscovered resources. As described in the Affected Environment section, there are 52 identified mineral resource tracts on the Tongass. Using the Forest-wide acreage breakdowns of LUD groups (as grouped in Table 3.14-2) by alternative indicates the overall effects on economic availability of mineral resources. Table 3.14-3 compares the Forest Plan alternatives using the cost/LUD group concept for the 52 areas with identified mineral resources (593,000 acres). For all seven alternatives, 25 percent of the acreage of identified mineral resources is in areas that have been withdrawn. Alternatives 7 and 4 have the fewest acres of identified mineral resources in allocations potentially causing higher costs for their exploration and development; Alternative 1 has the most acreage. The other four alternatives fall between these two in a fairly close grouping near the middle of the range.

Rank 1 mineral tracts are those most likely to see mineral exploration or development. Identified mineral resource areas in the Rank 1 category encompass an area of approximately 380,000 acres on the Tongass. Table 3.14-4 compares the Forest Plan alternatives using the cost/LUD group concept for these Rank 1 identified mineral resource areas. The results are similar to those indicated in Table 3.14-3. For all seven alternatives, 15 percent of the acreage of Rank 1 mineral

Table 3.14-3
Effects on Economic Availability of Identified Mineral Resources[1]

Alternative	Withdrawn Areas	Open Areas	
		Higher Cost	Average Cost
Alternative 1	25%	36%	39%
Alternative 2	25%	29%	45%
Alternative 3	25%	26%	49%
Alternative 4	25%	20%	55%
Alternative 5	26%	29%	45%
Alternative 6	25%	25%	50%
Alternative 7	25%	18%	56%

[1] Percentage of total area (593,000 acres) within each category.

Table 3.14-4
Effects on Economic Availability of Rank 1 Identified Mineral Resources[1]

Alternative	Withdrawn Areas	Open Areas	
		Higher Cost	Average Cost
Alternative 1	15%	36%	50%
Alternative 2	15%	28%	58%
Alternative 3	15%	25%	61%
Alternative 4	15%	19%	66%
Alternative 5	15%	31%	54%
Alternative 6	15%	24%	61%
Alternative 7	15%	17%	68%

[1] Percentage of total area (380,000 acres) within each category. Rank 1 mineral tracts have the highest likelihood of being developed.

resources has been withdrawn. Alternatives 7 and 4 again have the fewest acres of Rank 1 mineral resources in allocations potentially causing higher costs for their exploration and development, at 17 and 19 percent, respectively; Alternative 1 has the most (36 percent). The other four alternatives fall between these two in a fairly close grouping near the middle of the range.

A similar analysis has been performed for the 6.6 million acres of undiscovered mineral resources, as shown in Table 3.14-5 below. Here Alternative 1 again has the most acres in allocations potentially causing higher costs, followed by Alternatives 2, 3, and 5 or 6. Alternative 1 has the least area of LUDs assumed to have average costs for mineral development.

Table 3.14-5
Effects on Economic Availability of Undiscovered Mineral Resources[1]

Alternative	Withdrawn Areas	Open Areas	
		Higher Cost	Average Cost
Alternative 1	35%	57%	8%
Alternative 2	35%	51%	14%
Alternative 3	35%	45%	20%
Alternative 4	35%	35%	30%
Alternative 5	35%	41%	23%
Alternative 6	35%	41%	23%
Alternative 7	35%	33%	31%

[1] Percentage of total area (6.6 million acres) within each category.

The undiscovered mineral resource areas are also classified according to their estimated development potential, based on resource value. Class 1 and 2 undiscovered mineral areas are believed to have moderate to high per-acre mineral values. Table 3.14-6 shows the distribution of these Class 1 and 2 areas among the different LUD groups, by alternative. These table entries again show a consistent pattern in which Alternatives 7 and 4 are the least restrictive and Alternative 1 is the most restrictive with respect to likely mineral development costs.

Table 3.14-6
Effects on Economic Availability of Class 1 and 2 Undiscovered Mineral Resources[1]

Alternative	Withdrawn Areas	Open Areas	
		Higher Cost	Average Cost
Alternative 1	38%	50%	12%
Alternative 2	38%	43%	19%
Alternative 3	38%	37%	25%
Alternative 4	38%	26%	36%
Alternative 5	38%	39%	23%
Alternative 6	38%	36%	26%
Alternative 7	38%	25%	37%

[1] Percentage of total area (989,000 acres) within each category. Class 1 has a high mineral value per acre; Class 2 has a moderate mineral value per acre.

Only the 52 mineral activity tracts (identified resources) and adjacent areas were considered for allocation to the Minerals LUD. Table 3.14-7 shows how these allocations are distributed by alternative in terms of likely development cost. Even though all LUDs in the Open Area categories are expected to have average costs if they have a Minerals LUD overlay, it is likely that, even with the Minerals LUD overlay the higher cost LUDs identified in Table 3.14-2 would have slightly higher costs than the average cost LUDs. Therefore, Table 3.14-7 provides an indication of these smaller differences. With Alternative 1, 97 percent of the lands assigned the Minerals LUD overlay have underlying LUDs in the high-cost category. By comparison, Alternative 7 would result in only 43 percent in the high-cost category. Alternatives 2, 3, and 6 are similar to Alternative 1 in placing a higher proportion of the Minerals LUDs in high-cost areas than the average-cost areas, while Alternatives 4 and 5 have percentage distributions closer to Alternative 7.

Table 3.14-7
Effects on Economic Availability of Areas Covered by the Minerals LUD Overlay[1]

Alternative	Withdrawn Areas[2]	Open Areas[3]	
		Higher Cost LUDs, in the absence of Minerals LUD Overlay	Average Cost LUDs, in the absence of Minerals LUD Overlay
Alternative 1	1%	97%	2%
Alternative 2	1%	85%	14%
Alternative 3	1%	69%	29%
Alternative 4	1%	50%	49%
Alternative 5	0%	49%	51%
Alternative 6	1%	58%	40%
Alternative 7	1%	43%	56%

[1] Percentage of total area (249,570 acres).
[2] Note that the 3,000 acres in the Withdrawn Category are in Wilderness and cover prior rights only.
[3] Note that the Minerals LUD overlay converts all of these areas to the Average Cost category; however, there may still be some differences in cost.

Leasable and Salable Minerals

The effects of the Forest Plan alternatives on leasable minerals are not discussed in detail, as there are no aspects of the Forest Plan that would have a specific direct or indirect effect on activity related to leasable minerals. The Tongass has no current leasable mineral activity, and the anticipated demand for leasable minerals is expected to remain low. The Forest Service is aware of some level of interest in oil and gas, coal, and geothermal resources in specific areas of the Tongass. The proposed Forest Plan includes revisions to the standards and guidelines to address management of potential future leasable mineral activity. In general, those revisions provide that any mineral leasing activity would need to be consistent with the standards and guidelines for the respective LUDs affected by leasing. The revisions also include surface occupancy and other prescriptions intended to protect Forest resources in areas of leasing activity. The effects of any mineral leasing activity will be analyzed at the appropriate future time if the Forest Service receives specific requests for access to leasable minerals.

Salable or common variety minerals, primarily crushed rock, are utilized in each of the alternatives. Their predominant use is to construct roads in support of the Tongass National Forest transportation system, and thus the amounts used will correspond closely to the miles of new road construction by alternative. These are shown in *Chapter 2* as well as the *Transportation* section of this chapter.

Effects on Other Resources

The development of mineral resources in the Forest generally requires construction of an underground mine complex, a millsite, road and pipeline systems, tailings and waste rock disposal areas, a marine transfer/docking facility, and lodging accommodations if the mine location is not close to an existing community. Total surface-disturbing acreage can vary markedly with specific project characteristics; the operating Greens Creek mine involves about 320 acres for facility development, and the proposed Kensington mine project will use about 280 acres. The effects of any such development are analyzed at the time a specific project is proposed.

Cumulative Effects

The potential for cumulative effects associated with Forest Service management of minerals on the Tongass will depend upon the extent to which mining interests elect to pursue mineral exploration, development, and production activities on NFS lands in the future under the amended Forest Plan. Impacts from future mineral resource activities on the Tongass would add to the baseline impacts from past, present, and ongoing mineral activity within Southeast Alaska. Alterantive 5 would allocate about 171,000 acres to the Minerals LUD, and all of the other alternatives would allocate about 250,000 acres. This difference may indicate that Alternative 5 has a slightly lower potential for long-term cumulative effects; however, no major projects are proposed on these additional acres and NEPA analyses would need to be conducted prior to any project authorizations. Alternatives 4 through 7 allocate similar proportions (66 to 68 percent) of the Rank 1 known mineral resource tracts to LUDs expected to produce average mineral development costs, while the other alternatives would allocate from 50 to 61 percent of these areas to average-cost LUDs. Therefore, Alternatives 4 through 7 would have a relatively greater, but unknown, potential to contribute to cumulative effects associated with mineral activity. Other than mineral resources that are currently under development (specifically, the Kensington deposit), the Forest Service does not have sufficient information to identify any specific mineral development as reasonably foreseeable.

Recreation and Tourism

Affected Environment

The affected environment portion of the recreation and tourism analysis is divided into two broad sections, the first addressing the supply of recreation opportunities, and the second addressing existing use levels and trends. The supply section discusses the existing supply of recreation opportunities in terms of the Forest Service's Recreation Opportunity Spectrum (ROS) classes and inventoried recreation places on the Tongass. The existing use and trends section discusses overall forest use, resident recreation, tourism, and commercial outfitter/guide use.

The remainder of this introductory section provides a general overview of recreation in Southeast Alaska and the Tongass National Forest, which comprises approximately 80 percent of the region. Southeast Alaska possesses a remarkable and unique combination of features including inland waterways with over 11,000 miles of shoreline, mountains, fiords, glaciers, and large or unusual fish and wildlife populations that provide opportunities for a wide range of outdoor recreation experiences. Southeast Alaska imparts a sense of vastness, wildness, and solitude. These sentiments are enhanced by a small resident population and a relative absence of development compared to most other National Forests.

Recreation and tourism on National Forests encompasses more than the provision of facilities or recreation sites. This is especially true on the Tongass National Forest where most recreation and tourism attractions occur in remote undeveloped areas. Many Alaska residents purposefully live in proximity to such settings as a part of their lifestyle. Most visitors who travel long distances to see Alaska expect to find it in a wild and "unspoiled" state, but also expect comfort and convenience, reliable transportation, and other features requiring some level of infrastructure and development. The challenge to managers is to identify and understand the relationship between the settings and the variety of client groups. Commercial providers of recreation activities base much of their marketing strategy on particular environmental settings and identified recreation places within those settings.

The Tongass National Forest includes approximately 17 million acres of land available for recreation. This land contributes greatly to the feeling of vastness and solitude that dominates the region; however, much of the land is not suitable for outdoor recreation. Difficult and steep terrain, wetlands, icefields, glaciers, and heavy vegetation confine most recreation activities to accessible shorelines, river and stream bottoms, and around the many lakes within the Forest. Extensive use is made of some of the icefields and alpine areas (above tree line), but access to these areas is usually by aircraft. Both residents and visitors use the developed campground and picnic areas, beaches, trails, cabins, shelters, and visitor centers that are located near communities. A current inventory of developed recreation sites on the Tongass is presented in Table 3.15-1.

Table 3.15-1

The National Park Service manages 3.3 million acres in three park units in Southeast Alaska. The majority of this land is located within the Glacier Bay National Park and Preserve. The other two park units are the Sitka National Historic Park and Klondike Goldrush National Historic Park.

The State of Alaska also administers land for recreation. Many of the state land selections were made with recreation opportunities for the residents of local communities in mind. Most of these opportunities are still undeveloped. State selections were also made for future development of a system of marine parks. Currently, Alaska State Parks manages about 80,000 acres and 34 park units, including 16 marine parks, in Southeast Alaska. In addition, the Alaska Department of Fish and Game (ADF&G) manages two state wildlife refuges, two critical habitat areas, and one wildlife sanctuary, and the Alaska Division of Forestry manages the 247,000-acre Haines State Forest (Alaska State Parks 2004).

Community road systems are limited and heavily used for access to recreation sites and attractions near local communities. Existing road systems are primarily located near the larger communities of Juneau, Sitka, Ketchikan, Petersburg, and Wrangell. There is an extensive road system connecting the small communities on Prince of Wales Island, to systems developing near the communities of Hoonah and Kake. There is no interconnecting highway system between islands or between communities on the mainland.

Haines, Skagway, and Hyder all have highway connections to Canada and the Alaska Interior, as well as the lower 48 states, and serve as gateways for tourists heading north. Haines and Skagway are also visited by cruise ships and served by the Alaska Marine Highway System (AMHS).

Roads exist in other locations where timber harvest has taken place. Independent visitors from outside the state and residents from other parts of Southeast Alaska use road systems that are accessible from the AMHS ferries or from local communities for recreational purposes. Roads in locations where there are no communities or interconnecting access to the AMHS receive relatively low levels of recreation use. However, recreation-related vehicle use has been growing on some remote islands, including Kruzof, Zarembo, and Etolin Islands, and isolated systems on Kuiu and Kupreanof Islands. While the total amount of recreation use on these islands is low, it can be heavy at times, such as during hunting season.

Cruise ship passengers account for a large and growing share of visitors to Southeast Alaska. For example, the number of cruise ship visitors to Juneau more than doubled over the past decade from 462,542 in 1996 to 948,226 in 2005 (see Table 3.15-10). Other Southeast Alaska ports visited by cruise ships include Ketchikan, Sitka, Wrangell, Skagway, and Haines.

Supply of Recreation Opportunities

The supply of recreation opportunities is described in this analysis using two concepts: ROS and recreation places. These concepts describe the quantity of recreation opportunities. Quality is addressed using the "Home Range" concept and by assigning a value to the recreation places. These concepts are discussed in the following sections.

Recreation Opportunity Spectrum

The Tongass National Forest has the potential to provide a wide variety of recreation settings. The ROS has been developed to help identify, quantify, and describe these settings. The ROS system portrays the combination of activities, settings, and experience expectations along a continuum that ranges from highly modified to primitive environments. Seven classifications are identified along this continuum: Urban (U), Rural (R), Roaded Natural (RN), Roaded Modified (RM), Semi-Primitive Motorized (SPM), Semi-Primitive Non-Motorized (SPNM), and Primitive (P). The ROS inventory may be used to assess the potential effects of the alternatives on recreation settings.

The seven ROS classes are summarized in Table 3.15-2, based on seven elements that are considered in the allocation and management of recreation settings. Forest-wide ROS acres are presented in Table 3.15-3.

Viewed in terms of acres, the Primitive ROS setting is the largest on the Tongass, with approximately 10.4 million acres allocated to this setting (Table 3.15-3). The Wilderness and Natural Setting Land Use Designation (LUD) groups currently account for 47 and 45 percent of this total, respectively. Approximately 36 percent of the areas presently inventoried as SPNM (3 million acres) are located in the moderate development (12 percent) or intensive development (24 percent) LUD groups, with 19 percent located in existing Wilderness. Areas inventoried as SPM account for approximately 1.5 million acres Forest-wide and are mostly located in the Wilderness (31 percent) and Natural Setting (47 percent) LUD groups. Approximately 76 percent of areas allocated to the RN, RM, Rural, and Urban settings are located in the moderate development (23 percent) or intensive development (53 percent) LUD groups (Table 3.15-4).

Existing Wilderness on the Tongass is mostly associated with the Primitive ROS setting (82 percent), with the remaining 18 percent comprised of SPNM (10 percent) and SPM (8 percent). Much of the area inventoried as SPM on the Tongass is accessed via motorized watercraft. The Primitive ROS setting also comprises a large share of the Natural Setting LUD group (65 percent), with the remaining area allocated to other ROS settings, including 19 percent inventoried as SPNM (Table 3.15-4).

Table 3.15-2
Comparison of ROS Classes

	Urban (U)	Rural (R)	Roaded Modified (RM)	Roaded Natural (RN)
Scenic Quality	Alterations to landform and vegetation dominate landscape; nonrecreational activities not to exceed Low SIO - FG; Very Low SIO - MG.	Alterations to landform and vegetation dominate landscape; nonrecreational activities not to exceed Low SIO - FG; Very Low SIO - MG.	Alterations dominate the landscape; nonrecreational activities/structures evident, but do not exceed Very Low SIO.	Alterations to landscape subordinate; nonrecreational activities not to exceed Low SIO though typically Moderate SIO.
Access[1]	Access and travel facilities are highly intense, motorized, and often with mass transit supplements.	All methods of access and travel may occur, but subject to formal regulation.	All methods of access and travel when needed and compatible with intended activities.	All methods of access and travel may occur when compatible with intended activities; zones of non-motorized use.
Remoteness	Remoteness from sites and sounds of human activity not available or important.	Remoteness from sites and sounds of human activity not available or important.	Remoteness from continuous sounds of human activity is expected.	Remoteness from continuous sounds of human activity is of moderate importance.
Visitor Management	Intensive on-site controls are numerous and obvious.	On-site regimentation and control is obvious.	On-site regimentation and controls are few.	On-site regimentation and control is obvious.
On-site Recreation Development	Recreation structures and facilities readily evident, but appropriate for setting; designed for high use levels. Information and interpretive facilities may be large and complex.	Recreation structures and facilities readily evident, but appropriate for setting, designed for high use levels. Information and interpretive facilities may be large and complex.	Recreation structures and facilities may be present, but are provided primarily for protection of the resource rather than user convenience. Facilities are rustic and harmonize with a backcountry setting.	Recreation structures and facilities provided for site protection and user convenience. Facilities are contemporary but of rustic design and harmonize with natural setting.
Social Encounters	High concentrations of people at one time.	Moderate to high concentrations of people at one time.	Moderate concentration of users on roads and little evidence of others or interactions at campsites.	Interactions with others may be moderate to high. Moderate concentrations of people, especially on trails and in dispersed areas.
Visitor Impacts	Very noticeable, but managed to prevent physical resource degradation.	Very noticeable, but managed to prevent physical resource degradation.	Human use noticeable, but not degrading to resources. Site hardening dominates campsites, parking areas.	Visitor use noticeable, but not degrading to resources; established SIOs.

Table 3.15-2 (continued)
Comparison of ROS Classes

	Semi-Primitive Motorized (SPM)	Semi-Primitive Non-Motorized (SPNM)	Primitive (P)
Scenic Quality	Alterations few and subordinate to landscape; designed and located to not exceed Moderate SIO.	Alterations few and subordinate to landscape; nonrecreational activities and structures designed not to exceed High SIO.	Alterations to landscape not evident; structures do not exceed High SIO.
Access[1]	Travel on trails designed for/open to motor vehicles; roads maintained for high clearance vehicles; motorboats operating on waterways; may establish zones of non-motor use for facility/resource protection.	Trails closed to motorized use; nonmotorized boats used on freshwater lakes and streams.	Trails closed to motorized use; non-motorized boats used on freshwater lakes and streams.
Remoteness	Nearby sights and sounds of human activity are rare; distant sounds may occur.	Nearby sounds of human activity are rare; distant sounds may occur.	Sounds of human activity are very infrequent to nonexistent.
Visitor Management	On-site regimentation and controls are few.	On-site regimentation and controls are rare.	On-site regimentation and controls are very rare.
On-site Recreation Development	Recreation structures and facilities may be present, provided primarily for protection of site rather than user convenience. Facilities, when present, are rustic and harmonize with natural setting.	Recreation structures and facilities may be present but provided primarily for protection of site. Facilities, when present, are rustic and harmonize with natural setting.	Recreation structures are rarely present, provided primarily for the protection of the site. Facilities, when present, are rustic and harmonize with natural setting.
Social Encounters	Low interaction between users. Campsites seldom within sight or sound of another group except during peak periods.	Low interaction between users. Campsites seldom within sight or sound of another group except during peak periods.	Very low interaction between users and no other groups in sight or sound of overnight camps.
Visitor Impacts	Human use noticeable, but not degrading to resource or backcountry setting.	Human use noticeable, but not degrading to resource elements.	Human use essentially unnoticeable. Site hardening—boardwalks, boat moorings, food caches.

2. The total acres by ROS class shown in this table is slightly lower than the Forest-wide total because the ROS inventory does not include the entire Forest.

Recreation Places

Recreation Places are areas that are used for recreation activities and are easy to access. These areas are identified based on patterns of use associated with protected boat anchorages and landings, aircraft landing sites, and roads.

The Tongass offers a unique recreation setting because it provides an island and marine environment in close proximity to major mountain ranges and icefields. Forested mountains rising from the saltwater provide unique and remote coastal recreation opportunities not found in other areas of the United States. Recreation enthusiasts are able to view a variety of natural landforms and wildlife, such as glaciers, old-growth forests, humpback whales, spawning salmon, brown bears, and bald eagles. The immense amount of land on the Tongass National Forest provides a great diversity of recreation attractions and opportunities. Most recreation activities take place in, and are dependent on, settings that are primarily undeveloped and widely dispersed. The surrounding saltwater, which is not managed by the Forest Service, allows for motorized boat and floatplane access throughout Southeast Alaska.

The pattern of use associated with known protected boat anchorages, boat landings, aircraft landing sites, and the limited road systems makes it possible to identify specific “recreation places.” Recreation places are those areas that are used for recreation activities and are easy to access. Approximately 1,436 recreation places, totaling about 3.6 million acres (22 percent of the total Tongass National Forest), have been identified. Approximately 22 percent, or 311 of these places, are located in existing designated wildernesses. Although these areas comprise only 22 percent of the Forest-wide number of recreation places, they account for 36 percent of total recreation place acres.

The setting of a recreation place plays a key role in its attractiveness and use. Many recreation opportunities, such as viewing scenery or pursuing solitude, are dependent on this relationship and require a natural type of setting, whereas others, such as hunting or fishing, are less dependent on the type of setting. Table 3.15-5 identifies the distribution of recreation place acres by ROS class. Recreation places can be categorized into three general groupings based on their principle uses and attractions. These three general groupings, marine, freshwater, and land-based, are discussed in the *Recreation and Tourism* section of the 1997 Forest Plan Revision Final Environmental Impact Statement (EIS) (USDA Forest Service 1997a, pp. 3-107, 3-108). The distribution of recreation places among these general groupings is presented in Table 3.15-6.

For the purposes of this analysis, recreation places are classified in two basic ways. First, recognizing that access plays a key role in recreation in Southeast Alaska, “home ranges” were defined for each community. Inventoried recreation places were classified into two categories: those located within a radius of approximately 20 miles from communities (“home range”) and those outside (“rest of forest”). Almost half (48 percent) of the recreation place acres are within a community home range. Second, recreation places are identified as either important or ordinary/common based on five categories: facilities, marine, hunting, fishing, and tourism. The Forest Service developed this rating system in response to public comments received on the 1990 Draft EIS. Recreation places may be important for one, several, or none of the identified categories. Important recreation places by category are summarized in Table 3.15-7 and discussed further in the *Recreation and Tourism* section of the current Forest Plan Revision Final EIS (USDA Forest Service 1997a, pp. 3-109, 3-111).

Table 3.15-5
Distribution of Recreation Place Acres by Recreation Opportunity Spectrum Class

ROS Class	Acres (1,000s)
Primitive	1,306
Semi-Primitive Non-Motorized	916
Semi-Primitive Motorized	870
Roaded Natural	103
Roaded Modified	432
Rural and Urban	3

Note: These totals include all identified recreation places within the Tongass National Forest boundary, including those on state and private lands.

Table 3.15-6
Distribution of Recreation Places by General Use

	Number of Places	Percent of Total	Acres (1,000s)[1]	Percent of Total
Marine	617	43	1,234	34
Freshwater	302	21	908	25
Land-based	531	37	1,488	41
Total	**1,436**	**100**	**3,630**	**100**

[1] Updated acreages were calculated using the ratios from USDA Forest Service 1997a (pp. 3-107, 3-108) and the total acres identified in Table 3.15-5. Totals may not sum exactly due to rounding.

Table 3.15-7
Important Recreation Places by Category[1]

	Number of Places	Percent of Total[2]	Acres (1,000s)	Percent of Total[2]
Facilities[3]	402	28	1,053	29
Marine[4]	617	43	1,089	30
Hunting[5]	373	26	1,452	40
Fishing[6]	187	13	472	13
Tourism	876	61	1,924	53
Total Acres/Places	**1,436**	**NA**	**3,630**	**NA**

[1] Recreation places are rated as either important or common/ordinary.
[2] Percent columns sum to more than 100 because a recreation place can be rated important in more than one category.
[3] All recreation places with facilities were rated as being important. In addition, other recreation places with some type of facility, such as a viewing platform, and facilities authorized by a special use permit for recreation purposes, were identified as important.
[4] The marine category identified here is different to the marine type identified in Table 3.15-6. The marine category in this table only includes those recreation places that are truly unique or typify the Southeast Alaska marine experience.
[5] Important hunting areas were distinguished from ordinary hunting areas based on a number of factors, including heavy recurring use, hunter success, ease of access, opportunities for several species, and prized species, such as mountain goats and moose.
[6] Important fishing recreation places were identified using ADF&G ratings for recreational fishing.
Note: This estimate of total recreation place acres is slightly higher than the estimate used in the current Forest Plan Revision Final EIS (USDA Forest Service 1997a). The database used to develop these estimates has been updated and these estimates were developed using a more precise methodology than the grid-sampling approach that was employed in the 1997 Forest Plan Revision Final EIS analysis.
Source: USDA Forest Service 1997a (pp. 3-109, 3-111).

Existing Use Levels and Trends

The following section is divided into four parts that discuss forest use in general, resident recreation, tourism, and commercial outfitter/guide use on the Tongass National Forest.

Forest Use

Although there are some locations on the Tongass where fees are collected and locations where people can be easily counted, much of the information regarding general public use has been historically based on long-term observations, anecdotal information, and professional estimates, adjusted by quantitative indicators where available. In general, many residents and nonresidents seek the same type of recreation experiences and many engage in similar activities. Alaska has a reputation for vastness, rugged beauty, and solitude, and both residents and nonresidents usually expect to find these qualities in recreation settings. Expectations often vary by group and individual, however, with some people having higher expectations of wilderness and solitude than others.

The Alaska Region of the Forest Service (Region 10) began participating in the Forest Service's National Visitor Use Monitoring (NVUM) program in 2000. The final results of this program, which involved surveys conducted over 3 years, were published in August 2004 (Kocis et al. 2004). According to the NVUM analysis, there was an estimated total of 1.83 million National Forest visits and 2.13 million site visits to the Tongass in 2003 (Kocis et al. 2004). NVUM has standardized definitions of visitor use measurement to ensure that all National Forest visitor measurements are comparable. A National Forest visit, as defined by the NVUM, is the entry of one person onto the Forest to participate in recreation activities for an unspecified period of time and may include multiple site visits. A site visit, as defined by the NVUM study, is the entry of one person onto a National Forest site or area to participate in recreation activities for an unspecified period of time.

The results of the NVUM surveys on the Tongass indicate that the top five activities of survey respondents were viewing natural features (64.4 percent), hiking/walking

(59.6 percent), relaxing (32.5 percent), viewing wildlife (16.4 percent), and nature center activities (15.1 percent) (Table 3.15-8). Survey respondents were also asked to identify the primary activity that they were engaged in at the time of the survey. The top activities were hiking/walking (30.5 percent), viewing natural features (26.7 percent), fishing (8.3 percent), relaxing (8 percent), and gathering forest products (4.2 percent) (Table 3.15-8). Three of these activities (viewing natural features, hiking/walking, and relaxing) are also in the top five activities ranked by participation.

Table 3.15-8
Activity Participation and Primary Activities Identified in the 2004 Tongass NVUM Survey

Activity	Percent Participation	Primary Activity (Percent)[3]
Viewing Natural Features	64.4	26.7
Hiking/Walking	59.5	30.5
Relaxing	32.5	8.0
Viewing Wildlife	16.4	2.9
Nature Center Activities	15.1	3.1
Fishing	13.5	8.3
Nature Study	9.9	2.3
Picnicking	8.9	3.2
Gathering Forest Products	8.9	4.2
Driving for Pleasure	8.1	1.8
Motorized Water Activities	7.9	0.4
Visiting Historic Sites	6.2	0.3
Resort Use	4.1	1.9
Hunting	3.6	3.2
Other Non-motorized	3.2	0.6
Non-motorized Water	2.9	0.6
Other Motorized Activity	2.6	0.2
Bicycling	2.3	1.2
Backpacking	2.2	0.0
Developed Camping	1.7	0.6
OHV Use	1.3	0.0
Cross-country Skiing	1.0	1.0
Primitive Camping	0.6	0.1
Downhill Skiing	0.5	0.4
Horesback Riding	0.3	0.0
Snowmobiling	0.2	0.2

Resident Recreation

Many residents of Southeast Alaska place a high value on the quality and availability of outdoor recreation opportunities in the region. This is evidenced by the fact that the proportion of Alaskan residents who participate in outdoor activities is generally much higher than elsewhere in the United States (Bowker 2001). Many local residents engage in dispersed recreation activities on National Forest System (NFS) land and adjacent saltwater. Accurate data on this type of use are difficult to obtain and estimates tend to either underestimate the nature and extent of much of this use or overcompensate in inconsistent ways (USDA Forest Service 1997a, p. 3-120). The net result is that while there is a general consensus that outdoor recreation opportunities and activities provided by the Tongass are highly important to residents, there is limited data that accurately quantifies resident recreation use.

Resident recreation demand is influenced by a number of factors, including regional population levels, per capita participation rates, and recreation travel behavior. Over time, the supply of certain recreation opportunities in Southeast Alaska has increased. Road systems have expanded into previously inaccessible areas and visitor services and tourism marketing have also increased. In some cases, supply-induced increases in participation have occurred. This appears to be the case on Prince of Wales, Wrangell, and Mitkof Islands where road systems developed for timber harvesting created an opportunity for road-related access to previously inaccessible recreation settings and an opportunity for recreation activities involving wheeled vehicles.

Supply-induced participation changes have also been accompanied by additional demand for specific recreation places or facilities for a related activity. Increased opportunities for roaded access and activities are typically accompanied by a need for parking, dispersed campsites, picnic sites, trails to scenic attractions, and additional short access routes to cabin sites and previously inaccessible beaches. Increased tourism has resulted in increased demand for interpretive services as well as walking and hiking opportunities near the major communities.

The use of off-highway vehicles (OHVs) is another growing activity on the Tongass. Use is limited by topography, dense vegetation, and wet soils. These types of vehicles are most frequently used on road systems connected to communities, with riders seeking out primitive roads or spurs. Limited accessibility often results in OHV use on muskegs, beaches, tidal areas, and river channels during low flows.

A new travel management policy established for the Forest Service in 2005 requires each National Forest to identify and designate those roads, trails, and areas that are open to motor vehicle use. This policy is presently being implemented on the Tongass with each District Ranger required to seek public input and coordinate with federal, state, county, and other local governmental entities, as well as tribal governments, before any decision is made to consider use on a particular road, trail, or area. This decisionmaking process also involves completing National Environmental Policy Act (NEPA) analyses, as appropriate. Unplanned, user-created routes will be considered at the local level during the designation process (USDA Forest Service 2005e).

Tourism

Nonresident pleasure visitors or tourists can be divided into independent and package visitors. Independent visitors, who constitute a small but growing group, are characterized as those who get off the ferries and planes and engage in a variety of activities. They spend more time in the communities and on the Forest, and may secure the services of outfitters and guides, restaurants, motels, and transportation services such as floatplanes, boats, and gas stations. Independent travelers tend to plan their own itineraries, but often secure the services of mini-packages, such as day excursions or fishing charters. Approximately 89 percent of non-cruise ship visitors to Southeast Alaska in 2006 purchased some type of multi-day package (McDowell et al. 2007). These types of visitors compete more directly with residents for recreation opportunities on the Forest. Lodges have grown in popularity in recent years, with fishing lodges in particular playing an important role in the tourism industry in some local areas. A recent study, for example, identified nine recreational fishing lodges in the vicinity of Elfin Cove, a small town located west of Hoonah (Dugan et al. 2006). Fishing lodges accounted for 63 percent of the non-cruise, multi-day packages identified in 2006, with Wilderness lodges accounting for a further 13 percent of the total. Adventure tours (7 percent), rail packages (3 percent), motorcoach tours (3 percent), and “other” (12 percent) accounted for the remaining share of multi-day packages (McDowell et al. 2007).

Package visitors are typically the cruise ship clients, though some arrive by ferry and airplane. This is a very large group that uses the Tongass National Forest primarily as a scenic resource. These visitors spend less time in the area and generally follow preplanned and regimented itineraries. Shore excursions have, however, become an important part of the cruise ship experience, with much of this activity centered around communities. Half-day and day excursions into the Forest are also increasing in popularity.

The marketing of recreation opportunities by commercial suppliers has important similarities to resident recreation concerns. For example, many businesses that provide boat or aircraft access for wildlife viewing and other activities have a low tolerance for the presence of other groups in the same area. The presence of more than two or three other parties in a bay or area may cause such operators to seek substitute locations. The ability to market Alaska tourism, in part due to the high cost of visiting Alaska, is dependent on meeting customer expectations of seeing and experiencing vast, untamed land and its wildlife. Resident recreationists who traditionally use an area may, however, be discouraged by commercial businesses operating in the same area.

Reasons for Visiting Southeast Alaska

Two of the top three attractions in the state in 1993 were directly associated with the Tongass: the Inside Passage ranked first and Mendenhall Glacier ranked third. Southeast communities accounted for four of the six most frequently visited communities and places in the state: Juneau ranked second, Ketchikan third, Skagway fourth, and Glacier Bay sixth (USDA Forest Service 1997a).[1]

The most recent comprehensive survey of the motivations of visitors to Southeast Alaska was conducted in 1988. Outstanding scenery was identified as the most cited reason for visiting the region (Table 3.15-9). Opportunities for seeing whales, bald eagles, bears, and other wildlife add to the experience. Wildlife was the second most cited reason for visiting the area. Scenery and wildlife were the most frequently cited attractions by both independents and visitors as a whole (Table 3.15-9).

Table 3.15-9
Reasons for Visiting Southeast Alaska

Reason	Independents	All Visitors
Scenery	66%	66%
Wildlife	31%	35%
Recommendations	25%	25%
Visit friends/relatives	23%	7%
Fishing/hunting	19%	8%
Wildernesses	16%	13%
Specific attractions	13%	10%
Part of cruise	9%	60%
Advertising	7%	10%
Price	2%	8%

Source: USDA Forest Service 1997a (Table 3-37). (Original Source: Data Decisions Group 1989. *Southeast Alaska Pleasure Visitor Research Program*, Summer 1988, p. 20.)

As noted, the 1988 survey is the most recent comprehensive survey of this type. The State of Alaska has not commissioned any similar comprehensive surveys of the motivations of Southeast Alaska visitors since that time. The information summarized in Table 3.15-9 provides an interesting snapshot of visitor motivations in 1988, but the number of visitors to the region has more than doubled since 1993, with the number of cruise ship visitors increasing more than threefold over this period. While the exact percentages may be different, it seems reasonable to assume that the Tongass-specific reasons identified in 1988—scenery, wildlife, fishing/hunting, and wilderness—continue to be valid today.

[1] These data, presented in Table 3-35 of the current Forest Plan EIS, are originally from the 1993 Alaska Visitor Statistics Program (AVSP). These data have not been collected in subsequent AVSPs.

Although there has not been a similar comprehensive survey specifically designed to address the motivations of visitors to Southeast Alaska, the results of three more recent surveys provide some insight. These surveys are the 2001 statewide Alaska Visitor Statistics Program (AVSP)[2], a 2005 survey of non-cruise visitors to central Southeast Alaska, and a 2005 survey of cruise visitors to Juneau (Northern Economics 2002, McDowell Group 2006a, McDowell Group 2005).

The 2001 statewide AVSP found that sightseeing was far and away the most common non-business activity for summer visitors to Alaska in 2001, cited by 53 percent of visitors as the primary non-business activity they hoped to enjoy in Alaska on their trip (Table 3.15-10). The second most frequently cited activity—fishing—was identified by only 9 percent of those surveyed. These relatively low figures for everything but sightseeing are partially a product of the survey design with survey respondents asked to identify the primary activity rather than multiple activities, but also reflect the importance of sightseeing and the range of other available activities.

Table 3.15-10
Most Common Non-Business Activities for Visitors to Alaska, 2001

Activity[1]	Percent of Surveyed Visitors
Sightseeing	53
Fishing	9
Touring Glaciers	3
Hiking	3
Wildlife Viewing	3

[1] These are the five most common responses to the question: "What is the primary non-business activity you hope to enjoy in Alaska on this trip?" The results were not disaggregated by region.
Source: Northern Economics 2002.

The McDowell Group (2006a) found that fishing, cited by 49 percent of surveyed visitors, was the primary reason to visit most frequently cited by non-cruise visitors to central Southeast Alaska in 2005. Visit friends/family and outdoors/scenic beauty were identified by 32 and 22 percent of surveyed visitors, respectively (Table 3.15-11). Fishing was identified by 46 percent of surveyed visitors as the activity they enjoyed most on their trip, with outdoors/scenic beauty and visit family/friends cited by 43 percent and 20 percent of those surveyed, respectively (Table 3.15-11). These data are for visitors to central Southeast Alaska, but are likely to be broadly representative of all non-cruise visitors to rural areas in Southeast Alaska.

The McDowell Group also surveyed cruise ship visitors to Juneau in 2005 and provided summary data from similar surveys conducted in 2003 and 2001. A survey of cruise ship passengers docking at Juneau may be considered broadly representative of all cruise ship visitors to Southeast Alaska because most cruise ships visiting Southeast Alaska stop there. These data again support the importance of scenery and sightseeing to the overall visitor experience, with 44 percent of cruise ship passengers surveyed in Juneau in 2005 identifying scenery/sightseeing as one of their most enjoyed activities (Table 3.15-12). Glaciers and whale watching were identified by 27 percent and 16 percent of surveyed visitors in 2005, respectively. The top three cited activities in 2005—scenery/sightseeing, glaciers, and whale watching—were also the most frequently cited activities in 2001 and 2003.

[2] The AVSP is a significant visitor industry research project conducted periodically by the State of Alaska. The most recent study was conducted in 2006 (McDowell et al. 2007).

Table 3.15-11
Reasons for Visiting and Most Enjoyed Activities for Rural (Non-Cruise) Visitors to Central Southeast Alaska, 2005

Activity	Percent of Surveyed Visitors[1] Reason for Visit[2]	Percent of Surveyed Visitors[1] Most Enjoyed[3]
Fishing	49	46
Visit Friends/Family	32	20
Outdoors/Scenic Beauty	22	43
Wildlife	13	21
Inside Passage	11	NA
People	NA	12

[1] Central Southeast was defined for the purposes of the McDowell Group study as Petersburg, Wrangell, Kake, Alaska and Prince of Wales Island. Note: Multiple responses were allowed.
[2] Activities identified in response to the survey question: "Why did you choose to visit the Central Southeast Alaska area?"
[3] Activities identified in response to the survey question: "What did you enjoy most about visiting the Central Southeast Alaska area?"
Note: NA = not included in the top five cited activities for this category

Table 3.15-12
Most Enjoyed Activities for Cruise Visitors to Juneau, 2001, 2003, and 2005

Activity	Percent of Surveyed Visitors 2005[1]	2003	2001
Scenery/Sightseeing	44	34	20
Glaciers	27	20	18
Whale Watching	16	8	9
Shopping	15	5	7
Weather	9	3	2

[1] The percentages for 2005 sum to more than 100 because multiple responses were allowed in the survey for that year.
Source: McDowell Group 2005

Taken together, these studies indicate that the scenery and sightseeing are consistently among the top reasons, and in most cases the top reason, attracting visitors to Alaska, Central Southeast, and Juneau. They are also most frequently cited as "most enjoyed" by surveyed visitors. This is largely consistent among different types of visitors (i.e., cruise and non-cruise) and consistent with the results of the 1988 survey (see Table 3.15-9). The other activities identified as reasons for visiting in 1988 also show up in the more recent surveys to varying degrees. These results also suggest that while the scenery is important for all visitors, the relative importance of other activities varies by the type of visitor (cruise versus non-cruise) and the survey location.

The estimated number of summer visitors to Southeast Alaska more than doubled between 1993 and 2007, increasing from 502,800 in 1993 to 1.160.000 in 2007.

Trends in Visitation
The number of visitors to Southeast Alaska has increased considerably over the past decade. Statewide, the total number of summer visitors increased from 861,100 in 1993 to 1,631,500 in 2006, which equates to an average annual growth rate of 5 percent and a total net increase of 89 percent. The number of summer visitors to Southeast Alaska increased by 131 percent over the same time period, increasing from 502,800 in 1993 to 1,160,000 in 2006 (McDowell Group et al. 2007). Statewide, increases in cruise ship passengers accounted for 66 percent of the

growth in visitors between 1993 and 2006. Arrivals by air increased by 44 percent over the same period, while the number of visitors arriving by ferry, highway, and other modes of entry decreased (Northern Economics 2002, McDowell et al. 2007).

Data for 2006 indicate that 63 percent of visitors to Southeast Alaska entered Alaska via cruise ship, 32 percent entered by air, with 3 percent and 1 percent entering via highway and ferry, respectively (McDowell et al. 2007).

The number of cruise ship passengers visiting Juneau more than trebled between 1993 and 2005, increasing from approximately 306,600 in 1993 to 948,200 in 2005.

The number of cruise ship passengers visiting Juneau more than doubled between 1993 and 2000, increasing from approximately 306,600 in 1993 to 632,000 in 2000 (Table 3.15-13). This number has continued to grow over the past 5 years, with a total of 953,000 cruise ship visitors to Juneau in 2006, a 51 percent increase from 2000 and a more than threefold increase from 1993. The number of passengers docking at Juneau is considered representative of the total number of cruise ship passengers because most cruise ships visiting Southeast Alaska stop there.

Other ports in Southeast Alaska, including Ketchikan, Skagway, and Haines, also experienced net increases in passenger volumes during the 1990s. Sitka and Wrangell were exceptions to this general trend with absolute decreases in passenger volumes during the latter half of the 1990s. Recorded passenger volumes at Sitka decreased from a high of 252,256 in 1996 to a low of 160,652 in 2000, but have since increased, peaking with 256,782 passengers in 2003. A total of 229,793 cruise ship passengers visited Sitka in 2005 (USDA Forest Service 2001c, Sitka Convention and Visitors Bureau 2006). The subsequent decrease in passenger volumes at Sitka was likely associated with the start-up of the Icy Strait Point development in Hoonah (see below).

The rapid growth and sheer magnitude of the cruise ship industry has important implications for recreation planning on the Tongass. Shore excursions have become an integral part of the cruise ship experience, providing increased revenues for ship operators and opportunities for local entrepreneurs. Much of this activity has been concentrated at ports of call that accommodate large or mid-sized cruise ships. Recent survey data (2005) indicate, for example, that approximately 83 percent of cruise visitors to Juneau participated in at least one tour while they were in Juneau. Glacier tours were the most popular type of tour in 2005, with 42 percent of cruise visitors taking this type of tour. Wildlife/marine life viewing, the Mt. Roberts Tramway, and flightseeing via helicopter were also popular (McDowell Group 2005).

Alongside the international cruise lines, several small and mid-size cruise operators are active in the region, often taking their customers to places such as Metlakatla and Petersburg in addition to the larger communities. Icy Strait Point, an old cannery located approximately 1.5 miles from Hoonah, is Alaska's first cruise destination built specifically for tourists. Owned by the Hoonah Totem Corporation and operated by Pt. Sophia Development Corporation, this facility opened in 2004. A total of 67,620 cruise passengers visited Hoonah in 2004, 77,498 visited in 2005, and 135,519 cruise visitors were projected for 2006 (Cruise Line Agencies of Alaska 2006). Another destination of this type is planned by the Goldbelt Corporation for Hobart Bay, north of Petersburg.

While the number of cruise ship passengers visiting Juneau has more than doubled over the past decade, the total number of Southeast Alaska State ferry passengers has shown an overall pattern of decline, with about 36 percent fewer passengers served in 2005 than in 1990, 233,618 versus 363,122 (Table 3.15-13).

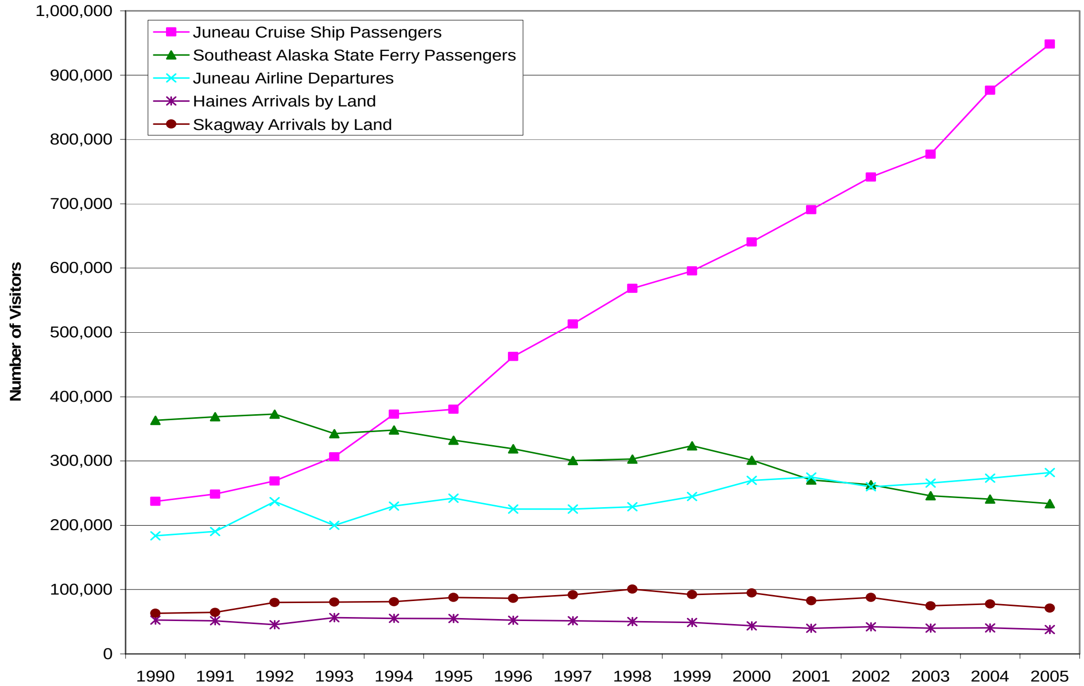
Table 3.15-13
Southeast Alaska Visitation, 1990 to 2005

Year	Juneau Cruise Ship Passengers[1,2]	Southeast Alaska State Ferry Passengers[2,3]	Juneau Airline Departures[2]	Haines Arrivals by Land[4]	Skagway Arrivals by Land
1990	237,070	363,122	183,677	52,719	63,237
1991	248,428	368,780	190,244	51,605	64,610
1992	269,000	372,680	236,824	45,355	79,946
1993[5]	306,600	342,613	200,066	56,406	80,709
1994	372,923	347,998	229,820	55,356	81,172
1995	380,529	332,312	242,084	55,148	87,977
1996	462,542	318,864	225,397	52,326	86,536
1997	513,181	300,653	225,397	51,495	91,849
1998	568,348	303,076	228,842	50,234	100,784
1999	595,595	323,540	244,645	48,997	92,291
2000[6]	640,477	301,176	269,880	43,621	94,925
2001	690,648	270,443	275,074	39,865	82,629
2002	741,512	263,040	259,759	42,290	87,851
2003	776,991	245,818	265,815	40,238	74,750
2004	876,203	240,666	273,152	40,438	77,837
2005	948,226	233,618	281,870	37,756	71,387

[1] These figures for passengers at Juneau are representative of cruise ship visitation trends because the majority of cruise ships visiting Southeast Alaska stop at Juneau.
[2] These data are presented for 1980 through 1994 in the 1997 Forest Plan Revision Final EIS (USDA Forest Service 1997a, Table 3-38).
[3] These totals do not include Inter-Island Ferry Association passengers.
[4] Arrivals by land are per passenger.
[5] The ferry Taku was out of service during May and June, which reduced total passengers.
[6] The ferry Columbia was out of service for most of the summer season, which reduced total passengers.
[7] The town of Hyder also receives a considerable number of arrivals by land. Based on estimates provided by the Hyder Community Association, approximately 28,000 visitors were recorded at the Fish Creek viewing platform in 1999. This number grew to 31,000 in 2001. A total of 35,676 visits were estimated at the viewing platform in 2005 (USDA Forest Service 2006f).
Sources: Alaska Department of Transportation 2006, Alaska Travel Industry 2006, Haines Convention and Visitors Bureau 2006, Skagway Convention and Visitors Bureau 2006, USDA Forest Service 1997a (Table 3-38) (Original Sources: Alaska Marine Highway Traffic Reports, Juneau Convention and Visitors Bureau, and Juneau Airport Manager's Office); USDA Forest Service 2001c.

Juneau airline departures increased between 1990 and 2005, but at a much slower rate than cruise ship passengers. Skagway and Haines arrivals by land stayed relatively constant over this period, showing an overall downward trend since the late 1990s (see Table 3.15-13 and Figure 3.15-1). Hyder also receives arrivals by land but data are not available for the early part of the decade. Essentially, all cruise ship use is by nonresident tourists. Ferry and airline passenger volumes and arrivals by land, on the other hand, also include Alaska residents and nonresidents visiting for reasons other than recreation and tourism, such as business or visiting relatives or friends. Larger communities also provide medical and other services that are not available in smaller communities.

Figure 3.15-1
Southeast Alaska Visitation, 1990 to 2005



Notes:
1. Longitudinal data are not available for arrivals in Hyder (see the note to Table 3.15-13).
2. State ferry data do not include Inter-Island Ferry Authority (IFA) passengers.
Source: See Table 3.15-13.

Data on the division between visitor and resident arrivals are not available for Southeast Alaska, but are available for the state as a whole. In summer 2004, residents accounted for an estimated 26 percent of total arrivals, down from 28 percent in 2001 (Northern Economics 2004, 2002). The percent of total arrivals accounted for by residents varied by type of transport, ranging from 0 percent for cruise ship arrivals to 44 percent of arrivals by highway and personal vehicle. Residents accounted for 41 percent and 38 percent of domestic air and international air arrivals, respectively, and 29 percent of arrivals by ferry (Table 3.15-14). These data are for the state as a whole, but are likely broadly representative of Southeast Alaska and illustrate the importance of the state ferry and domestic airlines to local residents.

Table 3.15-14
Alaska Arrivals by Transport Type and Visitor/Resident, Summer 2004

	Total Arrivals	Percent Visitor	Percent Resident
Domestic Air	1,030,200	59	41
International Air	44,800	62	38
Highway			
Personal vehicle	123,900	56	44
Motorcoach	13,400	85	15
Ferry	22,800	71	29
Cruise Ship	712,400	100	0
Total	**1,947,500**	**74**	**26**

Source: Northern Economics 2004.

The ferry data provided in Tables 3.15-13 and 3.15-14 and Figure 3.15-1 are for the AMHS only. These data do not include passengers transported by the Inter-Island Ferry Authority (IFA), which is a public corporation providing transportation to island communities in southern Southeast Alaska. Roundtrip service is currently (as of summer 2006) provided between Hollis and Ketchikan and seasonally from Coffman Cove to Wrangell and Petersburg.

Service has been provided between Hollis and Ketchikan since 2002. This service transported 25,197 passengers in 2002, its first year of operation. A total of 28,658 passengers were served by this ferry in 2005. The service between Coffman Cove and Wrangell and Petersburg was established in 2005 and served 2,955 passengers between May and August of that year (IFA 2006a). IFA ferries connect with vessels of the AMHS at Ketchikan, Wrangell, and Petersburg (IFA 2006b). The continued availability of these ferry services could affect resident recreation patterns in the future, as well as the recreation patterns of independent visitors to the region.

Visitation trends for two popular excursions, Juneau Icefield and Mendenhall Glacier, are presented in Table 3.15-15. The number of visitors to these areas has increased considerably since 1990. There were almost three times as many Juneau Icefield helicopter landing tour passengers in 2005 than in 1990, 93,902 versus 34,765. The number of visitors to the Mendenhall Glacier nearly doubled over this period, increasing from 188,000 in 1990 to 367,333 in 2005 (Table 3.15-15).

Table 3.15-15
Juneau Icefield and Mendenhall Glacier Visitation, 1990 to 2005

Year	Juneau Icefield Tour Passengers[1]	Mendenhall Glacier Visitors[1]
1990	34,765	188,000
1991	41,887	145,482
1992	45,638	160,000
1993	53,600	210,000
1994	62,449	265,000
1995	55,818	212,411
1996	65,709	276,000
1997	75,491	237,233
1998	84,632	238,366
1999	85,174	273,488
2000	85,531	NA
2001	89,961	236,340
2002	85,680	250,363
2003	85,407	284,867
2004	94,928	319,630
2005	93,902	367,333

[1] These data are presented for 1980 through 1989 in the 1997 Forest Plan Revision Final EIS (USDA Forest Service 1997a; Table 3-38).

Sources: 1990 to 1994: USDA Forest Service 1997a (Table 3-38) (Original Source: Juneau Ranger District Records); 1994 to 2000: USDA Forest Service 2001c; 2001 to 2005: USDA Forest Service 2006g; 2006h.

Commercial Outfitter/Guide Use

Outfitter/guides on the Tongass range from small family, run operations to larger corporations. Most firms serve less than 100 clients per year, with a smaller number of firms serving much larger numbers and one firm serving more than 100,000 clients in 1999.

The Forest Service authorizes commercial activities to make it easier for the public to visit National Forests. Due to its remote and rugged nature, recreation use on much of the Tongass National Forest requires good outdoor skills and/or specialized equipment. Commercial outfitters and guides provide access and equipment to assist people who might not otherwise be able to pursue certain recreation activities on the Forest. Outfitter/guides on the Tongass range from small family-run operations to larger corporations and non-profit organizations.

A survey of commercial recreation businesses in Southeast Alaska conducted in 2000 indicated that the majority of surveyed businesses were small, with 86 percent earning gross revenues of less than $100,000. Six firms reported revenues over $1 million, including one firm with revenues exceeding $10 million. A similar distribution is evident in terms of clients served, with the majority of firms serving less than 100 clients, a smaller number of firms serving considerably larger numbers, and one firm serving more than 100,000 clients in 1999 (Alaska Division of Community and Business Development [DCBD], 2001).

Both residents and nonresidents use the services of outfitter/guides, but nonresidents tend to use outfitter/guides more often because they do not have the local knowledge or necessary equipment. Local residents tend to use their own boats and equipment to reach the Forest. Personal boats are often smaller than charter boats used by nonresidents, resulting in visiting groups of residents generally being smaller than nonresident groups.

Outfitter/guides require special use permits to operate on the Tongass and are required to report annual use as part of their permit. In 2005, there were almost 270 special use authorizations issued for outfitter/guide services on the Tongass National Forest.

The survey of commercial recreation businesses in Southeast Alaska conducted in 2000 found that 73 percent of the businesses surveyed had experienced an increase in the number of clients they serve since 1995 (Alaska DCBD 2001). Nineteen percent reported no change over this period, with the remaining 8 percent reporting a decrease in number of clients served. Sixty-eight percent of responding firms indicated that they had been in business less than 10 years. Cruise ship passengers accounted for 41 percent of total clients for all of the surveyed businesses, ranging from 22 percent of clients for businesses with fewer than 200 clients a year to 91 percent of clients for businesses with more than 10,000 clients a year.

Recreation activities in Southeast Alaska and on the Tongass National Forest cover a broad spectrum of uses, ranging from fishing and hunting to helicopter flights and photography. The principle activities engaged in by the businesses surveyed in 2000 are identified in Table 3.15-16. Saltwater fishing was the most popular activity, followed by nature viewing/sightseeing, then wildlife viewing. The survey found that motorized watercraft was the most popular transportation mode used by commercial recreation businesses in Southeast Alaska.

Most outfitter/guides using the Forest shorelines access them via boat from saltwater. Some clients are dropped off on beaches, while others are also guided on land. The majority of charter boats in Southeast Alaska operate exclusively on saltwater for fishing or sightseeing without ever using the Forest (USDA Forest Service 2004g). These businesses are included in the data presented in Table 3.15-16.

While people often participate in several different activities in one or more settings on any given trip, different activities result in different numbers of people in a group and different amounts of time spent on the Forest. At one end of the spectrum, guided bear hunting consists of many small groups of one or two people. Hunters

Table 3.15-16
Principle Activities Engaged in by Southeast Alaska Commercial Recreation Businesses in 1999

Activity	Percent	Activity	Percent
Saltwater Fishing	63	Hiking, Mountain Climbing	14
Nature Viewing/Sightseeing	49	Cultural/Historical Sites	10
Wildlife Viewing	44	Camping	6
Photography	35	Backpacking	3
Motorized Boating	25	Northern Lights Viewing	3

Bird Viewing	21	Cross-Country Skiing, Snowshoeing	1
Non-Motorized Boating	15	Bicycling, Mountain Biking	1
Hunting	14		

Source: Alaska DCBD 2001

are dispersed across a large area and are on the Forest for long periods of time, typically 5 to 10 days, during spring and fall. At the other end of the use spectrum are mid-sized nature-viewing tour boats with relatively large group sizes (from 12 to 70 people). These groups are typically concentrated in a few areas of the Forest. Their use is short-term and concentrated in the summer season.

The Shoreline Outfitter/Guide FEIS, prepared for four northern Ranger Districts on the Tongass (USDA Forest Service 2004g), notes that recreation group size is highly variable along shorelines in that study's project area. Groups generally consist of less than 12 people, although larger groups, often associated with commercially guided groups from tour boats, may also be present. The largest shoreline group reported in the north part of the Forest in 1999 was a tour boat with 70 people.

This type of use accounts for a large number of visitors, but tends to be concentrated in relatively few areas of the Forest. Businesses providing services to these types of larger groups are heavily influenced by physical conditions that allow for large boat access and their schedules.

Helicopter landing tours are another form of outfitter/guide use that has been increasing in popularity in recent years. The number of clients and groups participating in helicopter tours are identified by area in Table 3.15-17.

Of 948,226 cruise ship passengers visiting Juneau in 2000, 93,902, or 10 percent, participated in helicopter landing tours on the Juneau Icefield (Tables 3.15-13 and 3.15-15). These tours to the Juneau Icefield involve high volumes of people concentrated at specific locations for short periods of time, typically 2 to 4 hours. Helicopter traffic, in groups of one to three helicopters, is almost continuous to and from icefield locations during the summer. Clients are typically outfitted and guided to walk, photograph, hike, or trek on, and explore the glacial environment.

Dogsled mushing tours on the Juneau Icefield are also increasing in popularity, with approximately 21,600 helicopter tour passengers engaging in this activity in 2005 (USDA Forest Service 2006i). This is more than twice the number of passengers (approximately 9,550) who participated in this type of tour in 2001. The number of helicopter passengers visiting the Juneau Icefield increased by 4 percent over this period, from approximately 90,000 to 93,900 (see Table 3.15-15). The large increase in the number of people taking dogsled mushing tours reflects the number of permitted helicopter tour operators offering this type of tour, with operators likely offering this type of tour in response to expressed and perceived demand. There were four permitted helicopter tour operators from 2001 through 2005. In 2001 and 2002, only one helicopter tour operator under permit offered dog mushing tours. In 2003 and 2004, there were two helicopter tour operators under permit who offered

Table 3.15-17
Helicopter Tour Locations by Client and Group, 2005

Area	Number of Groups[1]	Number of Clients
Juneau Icefield 1 – Gilkey Backcountry	600	2,702
Juneau Icefield 3 – Herbert	1,992	8,965
Juneau Icefield 4 – Mendenhall	11,736	52,813
Juneau Icefield 5 – Lemon	16	70

Skagway Icefield – Denver	2,360	10,621
Skagway Icefield – East Fork	58	262
Skagway Icefield – LeGrande	10	47
Skagway Icefield – Meade	811	3,648
Skagway Icefield – Shubee	32	142

[1] These numbers are an estimate of the number of helicopters based on an average helicopter group size of four to five passengers per trip.
Source: USDA Forest Service 2006h

dogsled mushing tours. In 2005, three of the operators under permit offered dogsled mushing tours (USDA Forest Service 2006g).

Helicopter landing tours also occur in a number of locations elsewhere on the Forest, including the Revilla and Spires (Patterson Glacier) roadless areas. The numbers of visitors are, however, much lower than those visiting the Juneau Icefield. In 2000, a total of 1,205 helicopter landing tour service days were reported for the Revilla Roadless Area, east of Ketchikan. A total of 727 helicopter landing service tour days were reported for the Spires Roadless Area, northeast of Petersburg. After 2000, this service was no longer available (USDA Forest Service 2006h). The number of helicopter passengers visiting Patterson Glacier, northeast of Petersburg, decreased by 42 percent, from 727 passengers in 2000 to 424 passengers in 2005 (USDA Forest Service 2006h).

Summary data for outfitter/guide use for 2004 and 2005 are presented in Table 3.15-18. This table identifies the number of reported outfitter/guide clients and groups by Ranger District. A total of 618,000 clients and 12,250 groups were reported in 2005, which represented a 22 percent increase in clients from 2004 and a 5 percent increase in the number of groups. The Juneau Ranger District accounted for 88 percent of the total clients in 2005, with 68 percent of these clients (366,191) visiting the Mendenhall Glacier Visitor's Center.

This diversity in the range of activities and types of recreation experience offered by outfitter/guide businesses can lead to conflicts between businesses when incompatible activities occur in close proximity. Comments received during the Shoreline Outfitter/Guide EIS process highlighted conflicts between helicopter and wheeled airplane access on one hand and some boat or foot travel access on the other. Several comments noted that the activities of smaller operations often tend to

be similar and compatible resulting in minimal conflicts, while larger operations often tend to detract from the setting and expectations of smaller groups. Some smaller operators believe that they are being displaced from their traditional use areas by larger commercial operations. On the other hand, some tour boat operators providing services to large groups felt they have been progressively excluded from areas on the Tongass National Forest over the past two decades (USDA Forest Service 2004g).

The number of big game guides has increased substantially over the past decade, which has raised concerns that current levels of guided hunting may not be sustainable due to increasing user conflicts and game population concerns. Some comments received on the Draft 2002 Forest Plan SEIS noted that growth in the guiding industry has led to these activities expanding into portions of Southeast Alaska that were not historically subject to this type of pressure. These types of concerns about user conflict are evaluated by the Forest Service when addressing the outfitter/guide experience provided on NFS lands. The Forest Service works with the State of Alaska and the Federal Subsistence Board to address game population concerns. The State of Alaska manages recreational hunting throughout the state, while the Federal Subsistence Board manages all federal lands in the state with respect to wildlife species taken for subsistence.

While many Southeast Alaska residents support the growing tourism industry, some residents are questioning the benefits and believe that unregulated growth of this industry would be detrimental and result in high social costs to communities. Concerns have been expressed that the existing and increasing level of commercial use is causing crowding or displacement of local residents and independent travelers who recreate on the Forest (USDA Forest Service 2004g). However, while some members of the public support limits on commercial use, others are concerned about the economic impacts of restrictions and limitations on commercial use.

Environmental Consequences

Direct and Indirect Effects

This section describes the potential direct, indirect, and cumulative effects of the proposed alternatives on recreation and tourism. The section is divided into three parts. The first two parts address effects on the supply of recreation opportunities and effects on recreation use and demand, respectively. The supply section discusses the effects of the alternatives on the existing supply of recreation opportunities in terms of the Forest Service's ROS settings and inventoried recreation places on the Tongass. The use and demand section discusses the potential effects on resident recreation and tourism. The final section summarizes the potential effects by alternative.

Effects on Supply

The following section discusses the potential effects of the proposed alternatives on ROS settings and recreation places.

Recreation Opportunity Spectrum

As discussed in the preceding affected environment section, the ROS system is designed to help identify and quantify different types of recreation setting on the Tongass National Forest and portrays the appropriate combination of activities, settings, and experience expectations along a continuum that ranges from highly modified to primitive environments (Table 3.15-2). The Forest-wide mix of ROS settings would vary by alternative. Estimated acres by ROS setting and alternative are presented in Table 3.15-19. The changes shown in this table are long-term changes that are expected to occur 150 years in the future and would take place gradually over several decades. ROS settings are projected to change in those areas allocated to intensive and moderate development LUDs. As a result, changes in settings are related to projected levels of future development. The ROS projections provide a general overview of how the recreation settings of the Forest would change over time with each alternative.

Viewed in terms of total Forest-wide acres, Alternatives 1 and 2 would provide the greatest amount of primitive and semi-primitive opportunities, with little change occurring from the existing condition. Alternative 7 would result in the greatest shift from the existing condition to roaded opportunities, followed by Alternatives 4, 5, 6, and 3, in that order. These shifts would occur as a result of timber harvest activities.

The percentage of acres classified as RM would increase over the 150-year period under all of the alternatives, including Alternatives 1 and 2. The largest gains would occur under Alternatives 4 and 7, with the percent of Forest-wide acres classified as RM increasing from approximately 10 percent to approximately 23 percent and 24 percent, respectively (Table 3.15-19). Under the most intensive timber harvest alternative (Alternative 7), approximately 66 percent of the Forest would remain at the undeveloped end of the recreation opportunity spectrum (Primitive and SPNM) after 150 years, a decrease of 14 percent from the current distribution.

It may be noted that these projections assume for the purposes of analysis that the supply of SPM settings would not increase over time. This is not necessarily the case. The ROS system helps identify, quantify, and describe recreation settings and essentially represents an inventory of existing recreation areas. Shoreline areas or other areas accessible by floatplane or helicopter that are presently allocated to Primitive or SPNM settings could be reallocated to the SPM setting in the future if patterns of use or other factors change. This type of change would result in an increase in the supply of SPM settings.

Table 3.15-19
Forest-wide ROS Acres after 150 Years of Implementation, by Alternative

	Primitive	SPNM	SPM	RN	RM	R+U	Total
Current	10,358,097	3,046,557	1,486,674	160,594	1,713,018	5,715	**16,770,654**

Notes:
SPNM=Semi-Primitive Non-Motorized, SPM=Semi-Primitive Motorized, RN=Roaded Natural, RM=Roaded Modified, R+U=Rural and Urban
1. The total acres shown in this table are slightly lower than the Forest-wide total because the ROS inventory does not include the entire Forest.
2. ROS settings are projected to change in those areas allocated to the Semi-Remote Recreation, Scenic Viewshed, Modified Landscape, and Timber Production LUDs. These projected changes are based on the following assumptions:
- Semi-Remote Recreation: 5 percent of Primitive, SPNM, and SPM would be converted to RN over the 150-year evaluation period.
- Scenic Viewshed: 25 percent of Primitive, SPNM, and SPM would be converted to RM; 25 percent of Primitive would change to SPNM; and 50 percent of Primitive and 75 percent of SPNM and SPM would stay the same over the 150-year evaluation period.
- Modified Landscape: 50 percent of Primitive, SPNM, and SPM would be converted to RM; 50 percent of Primitive would change to SPNM; and 50 percent SPNM and SPM would remain the same
- Timber Production: 80 percent of Primitive, SPNM, and SPM would be converted to RM; 10 percent of Primitive, SPNM, and SPM would change to RN; 10 percent of Primitive would become SPNM; and 10 percent of SPNM and SPM would remain the same.

Recreation Places

This analysis assesses the potential effects of the proposed alternatives on recreation places based on projected changes in the LUDs within which these places are located. In general, recreation places located in intensive and moderate development LUD groups would trend toward RM and RN setting opportunities in the future if they are not currently in these settings. Recreation places in the Natural Setting and Wilderness groups would likely retain their existing settings. It is important to remember that these effects are the result of long-term changes that are expected to occur gradually during the next 150 years.

Home Range Recreation Places

Home range recreation places are those inventoried recreation places within an approximate 20-mile radius from one or more communities. The long-term effects of the proposed alternatives on home range recreation places are summarized in Table 3.15-20. These effects are presented in terms of the distribution of recreation place acres by LUD group. Home range recreation places in development LUDs (moderate or intensive) would range from 10 percent of total home range acres under Alternative 1 to 44 percent and 40 percent under Alternatives 7 and 4, respectively. The percent of home range recreation place acres allocated to Wilderness LUDs would be 22 percent under all of the alternatives (Table 3.15-20).

Table 3.15-20
Home Range Recreation Places by LUD and Alternative (percent of acres)

1	22	67	5	6
2	22	58	9	10
3	22	53	12	13
4	22	37	19	21
5	22	48	14	15
6	22	49	13	15
7	22	33	21	23

Important Recreation Places

Recreation places are identified as either important or ordinary/common based on five categories: facilities, marine, hunting, fishing, and tourism. Individual recreation places may be important for one, several, or none of these categories. The following sections discuss the long-term effects of the proposed alternatives on important recreation places by category.

Facilities. The long-term effects of the proposed alternatives on important recreation places with facilities are summarized in Table 3.15-21. These effects are presented in terms of the distribution of recreation place acres by LUD group, which indicates the relative degree of potential impact that each alternative would have on existing recreation places with important facilities. The potential effects of timber harvest would likely vary by the type of facility. The importance of a remote public recreation cabin may, for example, be greatly enhanced by the solitude and natural scenery the area provides. This type of setting may be of only secondary importance for a similar cabin where the attraction might be the outstanding steelhead fishing in the spring.

Approximately 29 percent of inventoried recreation places acres are currently important for recreation facilities. The overall percentage of these acres that would be allocated to development LUDs (moderate or intensive) ranges from 5 percent (Alternative 1) to 21 percent (Alternative 7). The percent of recreation place acres important for facilities allocated to Wilderness LUDs would be 41 percent under all of the alternatives (Table 3.15-21).

Table 3.15-21
Recreation Places Important for Facilities by LUD and Alternative (percent of acres)

Alternative	Wilderness	Natural Setting	Moderate Development	Intensive Development
1	41	55	3	2
2	41	49	6	4
3	41	47	8	4
4	41	40	13	6
5	41	46	9	5
6	41	46	9	4
7	41	38	15	6

Marine. The long-term effects of the proposed alternatives on recreation places that are important for marine recreation are summarized in Table 3.15-22. These effects are presented in terms of the distribution of recreation place acres by LUD group. The perception of naturalness and scenery are very important values among Forest visitors engaged in the unique marine recreation opportunities offered by the

Tongass. Approximately 30 percent of inventoried recreation places acres are currently important for marine recreation activities. Many of these recreation places are within the beach fringe and are allocated to the SPM ROS.

The overall percentage of recreation place acres that are important for marine recreation and would be allocated to development LUDs (moderate or intensive) ranges from 4 percent under Alternative 1 to 33 percent under Alternative 7. The percent of recreation place acres important for marine recreation allocated to Wilderness LUDs would be 36 percent under all of the alternatives (Table 3.15-22).

Table 3.15-22
Recreation Places Important for Marine Recreation by LUD and Alternative (percent of acres)

Alternative	Wilderness	Natural Setting	Moderate Development	Intensive Development
1	36	60	3	1
2	36	54	6	5
3	36	48	7	9
4	36	33	15	15
5	36	43	9	12
6	36	43	9	12
7	36	31	17	16

Hunting. The long-term effects of the proposed alternatives on recreation places that are important for hunting are summarized in Table 3.15-23. These effects are presented in terms of the distribution of recreation place acres by LUD group. Hunters who favor hunting in an undisturbed, natural setting would likely prefer those alternatives that have the most acres in the Natural Setting and Wilderness LUD groups. Hunters who prefer using roads and road access would generally benefit from those alternatives with more acres in the intensive and moderate development LUD groups. Approximately 40 percent of inventoried recreation places acres are currently important for hunting.

The overall percentage of recreation place acres that are important for hunting and are allocated to development LUDs (moderate or intensive) would range from 5 percent under Alternative 1 to 41 percent under Alternative 7. The percent of recreation place acres important for hunting allocated to Wilderness LUDs would be 26 percent under all of the alternatives.

Fishing. The long-term effects of the proposed alternatives on recreation places that are important fishing places are summarized in Table 3.15-24. These effects are presented in terms of the distribution of recreation place acres by LUD group. There would be some variation in the Forest-wide standards and guidelines applied across the different alternatives, but all alternatives would maintain fish habitat. The

Table 3.15-23
Recreation Places Important for Hunting by LUD and Alternative (percent of acres)

Alternative	Wilderness	Natural Setting	Moderate Development	Intensive Development
1	26	69	2	3
2	26	64	4	7

5	26	45	10	20
6	26	49	9	16
7	26	33	13	27

quantity of fish available would likely remain constant across alternatives and immediate stream-side areas would remain natural along fish-bearing streams. It may, however, be noted that the Forest-wide beach and estuary fringe buffers would be reduced under Alternative 7.

Access to streams and areas immediately adjacent to streams may be subject to modifications at various levels. This may affect the quality of the fishing experience for some. Approximately 13 percent of inventoried recreation places acres are currently important for fishing.

Alternatives with more acres in the intensive and moderate development LUD groups would generally provide increased road access to fishing areas. However, the setting adjacent to the stream side corridors would appear more modified over time. The Natural Setting and Wilderness LUD groups maintain the settings in a more natural condition, with access generally more challenging. Access may affect the quality of the fishing experience regardless of the degree of setting changes leading up to the stream.

The percentage of recreation place acres that are important for fishing and would be allocated to development LUDs (moderate or intensive) ranges from 3 percent under Alternative 1 to 41 percent under Alternative 7. The percent of recreation place acres important for fishing allocated to Wilderness LUDs would be 31 percent under all of the alternatives (Table 3.15-24).

Effects on Use and Demand

The following section is divided into two parts that discuss the potential effects of the alternatives in terms of resident recreation use and tourism, respectively.

Resident Recreation

Forest-wide LUD allocations are presented by alternative in Table 3.15-25. This table also highlights the net change in development LUDs from Alternative 5 (No Action). Net changes in development LUDs would range from a 16 percent decrease under Alternative 1 to a 9 percent increase under Alternative 7. Projected changes in ROS settings are shown for 150 years into the future in Table 3.15-19. The effects of the LUD allocations on important recreation places are discussed in the preceding section.

Table 3.15-25
Forest-Wide LUD Allocations and Net Change in Development LUDs by Alternative (percent)

	Alternative

[1] This is the net change in Development LUDs as a share of total LUDs.

As noted in the Affected Environment part of this section, resident recreation demand, like other forms of recreation demand, is influenced by a number of factors, including regional population levels, per capita participation rates, and recreation travel behavior. The alternatives evaluated here are unlikely to affect broader trends in recreation behavior, but it is possible that they could result in different supply-induced changes in participation. These potential changes, along with the potential effects of the alternatives on recreation places, would likely affect resident recreationists.

Supply-induced changes in participation on the Tongass have, to date, been mainly related to changes in road systems and road access. This type of change in participation appears to have occurred on Prince of Wales, Wrangell, and Mitkof Islands, for example. In these locations, road systems developed for timber harvesting created an opportunity for road-related access to previously inaccessible recreation settings and, therefore, an opportunity for recreation activities involving wheeled vehicles. In addition, new roads that provide easier access to a wider area may create new semi-primitive opportunities that increases the capacity of a recreation place or creates a new recreation place.

While there would be some new road access under all alternatives in the long run, nearly all new roads constructed under the alternatives would be closed following harvest. These roads would, therefore, not be available for use by highway vehicles or high-clearance vehicles. They would, however, be available for access by other methods and would, as a result, have the potential to affect existing recreation patterns.

Viewed at a programmatic level, changes in participation related to road systems and access are more likely to occur under alternatives that involve higher levels of projected road construction. Based on the miles of new road construction projected under each alternative, Alternative 1 would have the lowest impact on existing recreation access patterns with less than half the road miles projected under Alternative 5 (No Action) (755 miles versus 3,881 miles). Also, new road construction under Alternative 1 would be almost entirely limited to areas outside existing Inventoried Roadless Areas (IRAs), and would, therefore, tend to increase road density in already roaded areas rather than provide new access to presently undeveloped areas.

Alternatives 2 and 3 would also have relatively low impacts on existing recreation access patterns with 1,798 and 1,072 fewer projected new road miles, respectively, than under Alternative 5. These alternatives would also limit the construction of new roads in IRAs and, therefore, limit potential changes in access, but to a lesser extent than under Alternative 1. Alternative 6 (Proposed Action) would have an effect similar to Alternative 5, while Alternatives 4 and 7 would involve 854 and 1,893 more new road miles, respectively, than Alternative 5, and have the potential to provide new access to presently undeveloped areas.

As the preceding discussion suggests, the general trend across all alternatives is toward an increase in motorized opportunities and a corresponding decrease in primitive recreation opportunities. Viewed at this level, Alternative 1 would have the lowest impact on primitive areas and associated opportunities because timber management would be limited to areas outside the existing IRAs on the Tongass. Alternatives 2 and 3 would have the next lowest potential impacts in that order, with timber management under Alternative 2 limited to areas outside the existing IRAs except in locations where existing roads could logically be extended. Alternative 3 would keep the 23 areas proposed for wilderness in House Resolution (HR) 987 and the 18 special interest areas in the 1999 Record of Decision (ROD) in a natural condition. Alternatives 5 and 6 would be more likely to involve timber harvest in IRAs, and this likelihood would be increased further under Alternatives 4 and 7. Alternatives 4 and 7 have an increased emphasis on timber production with respective long-term annual Allowable Sales Quantities (ASQs) of 342 million board feet (MMBF) and 421 MMBF compared to 267 MMBF under Alternative 5 and 49 MMBF under Alternative 1.

Given the programmatic nature of this planning document, it is not possible to predict site-specific changes that would occur under any of the alternatives. Potential impacts to recreation places and recreation activities in other areas would be evaluated on a project-by-project basis and in accordance with the applicable Forest Plan standards and guidelines under all alternatives. The Forest-wide standards and guidelines and LUD prescriptions of the current Forest Plan would continue to be implemented as part of Alternative 5, where they apply. An updated and edited version of the current Forest Plan (Volume II), which includes edits to the existing Recreation and Tourism Standards and Guidelines, would apply under all of the action alternatives, with some exceptions for Alternatives 4 and 7.

These edits include changes to OHV management and wilderness group sizes and use. Under the updated Forest Plan, OHV planning would be in accordance with 36 CFR 212, 251, and 261—Travel Management; Designated Routes and Areas for Motor Vehicle Use. Under the existing Forest Plan, open roads on the Forest are designated open to OHVs unless site-specific closures are made. Although not specified in the current Forest Plan, the new travel management rule is presently being implemented on the Tongass. Travel management would, as a result, be the same under all alternatives.

Recreation activities in Wilderness would be managed to meet appropriate levels of social encounters. This would include limiting group sizes to no more than 12 persons for commercial and general public use of a wilderness, limiting the length of stay at one location to 14 days, and limiting commercial recreation use to two groups of 12 people from a single vessel (or other form of transportation), with the groups required to disperse out of sight and sound from each other. Exceptions may be approved by the District Ranger or Monument Ranger in response to unusual circumstances. The updated Forest Plan authorizes one exception—the Stikine River valley—where larger group size would be allowed for general public use. Outfitted groups would still be required to comply with the 12 person limit.

The Forest will change over time under all of the alternatives, including Alternative 5, and recreation demand and use patterns are also likely to change. Recreationists may respond to changes to specific areas and locations in three general ways. Many will likely adapt to new situations, and changes in settings will have little or no impact to these current Forest users. For others, change may not be acceptable, and these users will be displaced to other areas where the setting and use patterns are more in line with their expectations and needs. A third group of current recreationists may find that they cannot adapt to the new situation nor find suitable substitute areas, and as a result, substitute other leisure activities in place of recreating on the Forest.

Tourism

The tourism industry and number of visitors to Southeast Alaska has increased dramatically since the early 1990s, with much of this growth linked to increased cruise ship travel to the region. Cruise ships bring the most visitors to Southeast Alaska, accounting for approximately 63 percent of visitors in 2001 (McDowell et al. 2007). Future development of the tourism industry in Southeast Alaska and elsewhere in the United States is dependent on a wide range of factors, including the value of the dollar in foreign countries, the price of oil, world events and international unrest, and political and social change. In addition, regions like Southeast Alaska directly compete with other locations and activities for tourist dollars. As a result, changes in other tourist markets, both positive and negative, have the potential to affect the tourism industry in Southeast Alaska. These factors are, for the most part, unrelated to management of the Tongass National Forest.

Other potential factors affecting tourism development in the region include the reactions of local communities and residents to increased tourism development. Cruise ship visitation is concentrated in a few locations in the region with the large ships usually calling at five key ports: Juneau, Ketchikan, Skagway, Sitka, and Haines. This concentration results in an uneven distribution of tourism-related benefits throughout the region, as well as a concentration of tourism-related concerns in particular communities (Schroeder et al. 2005). There is some evidence that there may be limits to the amount of unconstrained tourism development that Southeast Alaska communities are willing to tolerate. Local initiatives aimed at managing tourism include an advisory measure to limit the number of cruise ship dockings in Haines, which was approved by voters in 2000, as well as initiatives in Juneau and Haines proposed in response to helicopter and floatplane traffic over residential areas. Another example of local reaction was provided by Sitka voters who rejected a measure in 2000 to expand the public dock in Sitka to accommodate cruise ships (Schroeder et al. 2005). In addition, Alaska voters recently approved the Alaska Cruise Ship Ballot Initiative that established a statewide tax of $50 per passenger on cruise ship passengers visiting Alaska.

While it is reasonable to assume that the vast majority of tourism activity in the region is related to the natural environment, many visitors experience the Tongass passively—from the deck of a cruise ship, for example—without directly using the Forest for recreation purposes. The alternatives would have very little effect on this type of visitor because the scenic quality of heavily traveled cruise ship corridors and tourism industry use areas would be largely protected under all of the alternatives. The Scenery Standards and Guidelines provide special emphasis for scenic quality in LUDs allowing timber harvest in visual priority travel routes and use areas. This is discussed further in the *Scenery* section of this chapter.

However, cruise ships have heavily marketed Forest-related activities in recent years, and many passengers take at least one trip to the Forest during their visit, with icefield helicopter tours and visits to the Mendenhall Glacier by cruise ship passengers increasing substantially (Table 3.15-15). As discussed in the affected environment portion of this section, the tourism industry and outfitter/guides in Southeast Alaska offer a wide spectrum of recreation activities, ranging from guided bear hunting through helicopter tours and guided wildlife-viewing boat tours. Viewed in terms of Forest management, the requirements of these activities are often at odds with one another. Some activities require developed facilities, utilities, and easy access, while others require vast and remote areas in a natural setting, with outfitter/guides providing only the basic essentials for their clients.

The following discussion addresses the potential effects of the alternatives on recreation places important for tourism and future recreation and tourism developments.

Recreation Places Important for Tourism

The effects of the proposed alternatives on recreation places that are important for tourism are summarized in Table 3.15-26. These effects are presented in terms of the distribution of recreation place acres by LUD group. Approximately 53 percent of inventoried recreation places acres are currently considered important for tourism. All of the proposed alternatives provide a mix of opportunities, with some alternatives emphasizing natural settings and others allowing more timber harvest and road building. These changes may be viewed as opportunities or detriments to various sectors of the tourism industry and their clients. Based on numerous surveys and marketing campaigns for visitors, it is widely accepted that natural beauty and scenery are some of the principal factors attracting visitors to the region. However, the State of Alaska and part of the tourism industry expressed a desire during the planning process for the current Forest Plan for increased access and opportunities for development, as they believed that some existing areas are at or near capacity (USDA Forest Service 1997a, p. 3-136).

There are indications that demand exceeds supply in some recreation places, especially those used more extensively by tourist operators and outfitter/guides. Activities that are presently near or at capacity include bear-viewing areas and helicopter use in the immediate vicinity of urban areas. Other areas may be able to accommodate current levels of tourism and potential increases in the future without negatively affecting the tourist experience or causing detrimental environmental effects. The number of visitors cruising the Inside Passage or viewing Mendenhall Glacier may, for example, be sustainable at current and future levels of use (Schroeder et al. 2005).

Table 3.15-26
Recreation Places Important for Tourism by LUD and Alternative (percent of acres)

Alternative	Wilderness	Natural Setting	Moderate Development	Intensive Development
1	46	51	2	1
2	46	47	4	3
3	46	43	5	6
4	46	34	10	10
5	46	40	7	7
6	46	40	6	7
7	46	33	11	10

The overall percentage of recreation place acres that are important for tourism and would be allocated to development LUDs (moderate or intensive) ranges from 2 percent under Alternative 1 to 21 percent under Alternative 7. The percent of recreation place acres important for tourism allocated to Wilderness LUDs would be 46 percent under all of the alternatives (Table 3.15-26).

Given the programmatic nature of this planning document, it is not possible to predict site-specific changes that would occur under any of the alternatives. Management practices for specific areas, such as limiting the number of visitors by permit, would continue to be evaluated on a project-by-project basis and in accordance with the applicable Forest Plan standards and guidelines under all alternatives. The Forest-wide standards and guidelines and LUD prescriptions of the current Forest Plan would continue to be implemented as part of Alternative 5, where they apply. An updated and edited version of the current Forest Plan, which includes edits to the existing Recreation and Tourism Standards and Guidelines, would apply under all of the action alternatives, with some exceptions under Alternatives 4 and 7. These edits are discussed further in the preceding section that address effects to resident recreation.

Assuming that the volume of tourists remains at its current level or continues to increase as it has done over the last decade, the overall recreation trend would likely be toward more group experiences on the Tongass and less opportunities for solitude and isolation in natural areas close to cruise ship stops (Schroeder et al. 2005).

Developments

Increased tourism has led to the development of new tourism facilities in Southeast Alaska, including the Icy Point Strait development near Hoonah. The rapid growth and large volume of cruise ship passengers and the growth in shore excursions suggest that there will be demand for new developed facilities on the Tongass in the future. This section identifies the share of the Forest that would be available for recreation and tourism developments under each alternative.

The recreation and tourism Forest-wide standards and guidelines in the current Forest Plan address commercial development of facilities and opportunities by LUD. Developments are classified as either major or minor. These standards and guidelines remain substantially unchanged in the Proposed Forest Plan accompanying this EIS. Abbreviated definitions of these terms are provided below.

> **Major Development.** Major recreation and tourism developments provided by the private sector involve a long-term commitment of the land base, with a moderate to high level of site modification. They involve large buildings or complexes of buildings and facilities, and often provide several services in a concentrated area. Comfort and convenience are provided for guests, and facilities can generally accommodate more than 12 people. Subsequent site reclamation involves extensive removal of facilities; improvements, revegetation, recontouring, etc.; and a period of at least 5 years to attain a natural appearance.
>
> Examples of this type of development include destination resorts and lodges, food and beverage services, downhill ski areas, marinas and gas stations, and full-service campgrounds.
>
> **Minor Development.** Minor recreation and tourism developments provided by the private sector involve only minor site modifications. They involve small rustic facilities and/or improvements, generally with a single purpose or service, and may involve several sites or an extensive area. Basic essentials are typically provided and can generally accommodate 12 or fewer people per site. Site reclamation involves simple removal of facilities and little or no revegetation; a natural appearance can be attained in a few years.
>
> Examples of this type of development include cabins, huts, small docks, cross-country ski trails with simple facilities, temporary or portable camps, and simple rustic campgrounds.

The major and minor recreation development standards and guidelines by LUD are summarized in Table 3.15-27. The percent of Tongass acres available for major or minor tourism development is presented by alternative in Table 3.15-28.

Both major and minor developments are prohibited in Wilderness, National Monument Wilderness, and Research Natural Areas, which together account for approximately 35 percent of the Forest under all alternatives. Major developments are also prohibited in Wild River LUDs, which account for about 1 percent of the Forest. Major developments are discouraged in the Municipal Watershed, Remote

Recreation, and Experimental Forest LUDs and LUD II areas (Table 3.15-27). These LUDs account for 17 to 19 percent of all of the alternatives (Table 3.15-28). Minor developments are discouraged in the Municipal Watershed and Experimental Forest LUDs, which, combined, account for less than 1 percent of the Forest (Table 3.15-28).

The share of the Forest that would be compatible with major or minor recreation developments ranges from 20 percent under Alternatives 4, 5, and 7 to 31 percent under Alternative 1. The Semi-Remote Recreation LUD accounts for most of the compatible lands and ranges from 15 percent of the Forest under Alternatives 4 and 7 to 32 percent under Alternative 1 (Table 3.15-28). Developments in other parts of the Forest would be evaluated on a case-by-case basis. The share of the Forest where major developments would be evaluated on a case-by-case basis ranges from 13 percent under Alternative 1 to 27 percent under Alternatives 4 through 7.

Table 3.15-27
Major and Minor Recreation Developments by LUD

	Major	Minor
Not Allowed	Wilderness Wilderness National Monument Research Natural Area Wild River	Wilderness Wilderness National Monument Research Natural Area
Discouraged	Nonwilderness National Monument Remote Recreation Municipal Watershed LUD II Experimental Forest	Municipal Watershed Experimental Forest
Case-by-Case	Special Interest Area Old-growth Habitat Scenic River Modified Landscape Timber production Minerals Transportation and Utility Systems	Nonwilderness National Monument Remote Recreation Special Interest Area Old-growth Habitat Wild River Modified Landscape Timber production Minerals Transportation and Utility System LUD II
Compatible	Semi-Remote Recreation Recreational River Scenic Viewshed	Semi-Remote Recreation Recreational River Scenic Viewshed Scenic River

Notes:
Not Allowed: Recreation special-use developments are not allowed by law or regulation or are not consistent with agency policy and regulations.
Discouraged: Recreation special-use developments are generally not consistent with the objectives of the LUD. Development proposals require scrutiny of magnitude and scope for LUD conformance.
Case-by-Case: Recreation special-use developments may be compatible with the LUD objectives depending upon the scope, purpose, and magnitude of the proposal. Proposals will be evaluated on a case-by-case basis.
Compatible: Recreation special-use developments are generally compatible with this LUD, and applicants are encouraged to examine these areas first where there is a public need and no private lands are available or suitable for development.

Note: See the notes to Table 3.15-27 for an explanation of Not Allowed, Discouraged, Case-by-Case, and Compatible.

Development of tourism opportunities is a cooperative effort. Investments in the development of tourism facilities, such as destination resorts, are typically the responsibility of the private sector. Federal, state, and local agencies may also play a role in facilitating the development of these types of opportunities. The LUDs and standards and guidelines that would apply under each alternative provide a framework within which these types of developments may take place. They also provide direction for the Forest Service to respond to and address the needs of the recreation and tourism industry.

Juneau Icefield Land Use Designation

The LUD classification for the area north of Juneau that encompasses the Juneau Icefield would be changed from Remote Recreation to Semi-Remote Recreation under all of the action alternatives. The areas would remain classified as Remote Recreation under Alternative 5, No-Action Alternative. This change has been proposed because the snow accumulation zone on the icefield has retreated to higher elevations as a result of climate change, which has resulted in a number of minor development sites (e.g., dog sled camps) becoming unsuitable for use as the thinning snow layers expose crevasses during the middle of the operating season. The proposed change in LUD boundaries would allow the Forest Service to consider moving minor developments into areas with snow, where these types of development would not be allowed under the existing LUD. This proposed change would not affect the Forest Service's ability to allow an expansion of helicopter landing sites in the area, because glacier landing tours are allowed under both the existing (Remote Recreation) and proposed (Semi-Remote Recreation) LUDs for this area.

Effects by Alternative

The following section discusses the potential impacts by alternative.

Alternative 1. This alternative would keep all remaining IRAs in a natural condition. This alternative would preserve the largest amount of Primitive and Semi-Primitive recreation opportunities both Forest-wide and within community home ranges. Alternative 1 would also maintain existing recreation places located within IRAs in their current natural condition. Potential changes in access resulting from new road construction would be almost entirely limited to areas outside the existing IRAs. This alternative would most closely maintain current outdoor recreation setting conditions Forest-wide and support the maintenance of existing use patterns and opportunities.

There would be a relatively small shift toward the Roaded end of the ROS under this alternative, with approximately 78 percent of the Forest expected to be either Primitive or SPNM after more than 100 years, compared to approximately 80 percent at present. There would be an increase in the share of important recreation places in Natural Setting LUDs relative to Alternative 5.

Alternative 2. This alternative would keep most IRAs in a natural condition and emphasize a wide range of recreation and tourism opportunities in a natural setting. This alternative would preserve the second largest amount of Primitive and Semi-Primitive recreation opportunities after Alternative 1 both Forest-wide and within community home ranges. Potential changes in access resulting from new road construction would take place on lands outside of IRAs except for some areas where roads could be logically extended. This alternative would largely maintain current outdoor recreation setting conditions Forest-wide and support the maintenance of existing use patterns and opportunities.

The shift toward the Roaded end of the ROS would be larger under this alternative than under Alternative 1, but still relatively small, with approximately 77 percent of the Forest expected to be either Primitive or SPNM after 150 years, compared to approximately 80 percent at present. There would be an increase in the share of important recreation places in Natural Setting LUDs relative to Alternative 5.

Alternative 3. This alternative provides a mix of National Forest uses and activities similar to Alternative 2, with additional emphasis on timber management. This alternative would keep the 23 areas proposed for Wilderness in HR 987 and the 18 Areas of Special Interest in the 1999 ROD in a natural condition.

There would be smaller amounts of Primitive and Semi-Primitive recreation opportunities preserved under this alternative than under Alternatives 1 and 2, but still a relatively large amount, both Forest-wide and within community home ranges. Potential changes in access resulting from new road construction would take place in lands outside of the 23 areas proposed for Wilderness in HR 987 and the 18 Areas of Special Interest in the 1999 ROD.

Approximately 73 percent of the Forest would be either Primitive or SPNM after 150 years, compared to approximately 80 percent at present. There would be an increase in the share of important recreation places in the Natural Settings relative to Alternative 5 for all categories except facilities, where the share of important recreation places in Natural Setting LUDs would remain essentially the same as under Alternative 5.

Alternatives 4 and 7. Alternative 4 would provide for a mix of National Forest uses, with an emphasis on timber production. Timber management would occur in some IRAs not managed for timber production in the current Forest Plan. This would also be the case under Alternative 7, which would place additional emphasis on timber. Timber would be managed on a considerably expanded land base compared with the current Forest Plan (Alternative 5) and on a larger land base than under Alternative 4.

These alternatives would place a relative emphasis on the roaded end of the ROS spectrum, with 23 percent of the Forest expected to be RM after 150 years, compared to approximately 10 percent at present. This would be matched with a corresponding decrease in Primitive and SPNM settings, which combined would comprise about 67 percent of the Forest after 150 years under both alternatives compared to 80 percent at present.

These alternatives would involve the largest amount of new road construction, with approximately 4,735 miles and 5,774 miles projected under Alternatives 4 and 7, respectively, compared to about 3,881 miles under Alternative 5. While there would be a relative increase in new roads, with access provided to presently undeveloped areas, nearly all new roads would be closed following harvest and would, as a result, not be available for use by highway or high-clearance vehicles. The closed roads would, however, be available for access by other methods and would, as a result, have the potential to affect existing recreation patterns.

The share of home range recreation places within Wilderness and Natural Setting LUD groups would decrease from 79 percent under the current Forest Plan (Alternative 5) to 59 percent and 55 percent under Alternatives 4 and 7, respectively. There would be a decrease in the share of important recreation places in Natural Setting LUDs relative to Alternative 5.

Alternatives 5 and 6. Alternative 5 (No Action) is the current Forest Plan (1997 ROD, as amended) and provides for a moderately high level of timber production along with strong resource protection measures. Alternative 6 (Proposed Action) is similar to Alternative 5, but includes adjustments to the plan based on information generated during the recent 5-Year Plan Review and other minor clarifications and updates.

These alternatives would provide a mixture of Primitive and Roaded recreation opportunities relative to the other alternatives, which range from maintaining almost all IRAs in a natural condition (Alternative 1) to intensive timber management (Alternatives 4 and 7). Approximately 71 percent of the Forest would be either Primitive or SPNM under Alternatives 5 and 6 after 150 years, compared to approximately 80 percent at present. Approximately 19 percent of the Forest would be RM compared to 10 percent at present and 11 percent under Alternative 1 after 150 years.

There would be more new roads constructed under these alternatives than under Alternatives 1 through 3 and fewer than under Alternatives 4 and 7. The share of home range recreation places within Wilderness and Natural Setting LUD groups would be lower under these alternatives than under Alternatives 1 through 3 and higher than under Alternatives 4 and 7. This would also be the case with the share of important recreation place acres within Wilderness and Natural Setting LUDs.

Cumulative Effects

This section considers the incremental effects of the alternatives when added to other past, present, and reasonably foreseeable actions. The effects of past and present actions on recreation are included in the Affected Environment portion of this section, which discusses current recreation facilities and activities on the Tongass. Past actions include past timber harvest and road building that has facilitated roaded recreation and changed ROS settings, as well as the development of recreation facilities, such as cabins, campgrounds, interpretive sites, and visitor centers. Present actions include the impacts of current management policies on existing recreation patterns, particularly those that are authorized by special use permits.

One of the major trends in recreation in Southeast Alaska has been the continued growth in the number of cruise ship passengers visiting the region. The effects of the alternatives are considered in conjunction with this trend because it underpins current and future recreation demand on the Tongass. Current recreation patterns on the Tongass also reflect past timber harvest and road building activities on adjacent private and Native corporation lands, as well as wildland recreation opportunities on federal- and state-managed lands elsewhere in the region.

Reasonably foreseeable actions on NFS lands include the projected levels of future timber harvest and road building that are used in the preceding analysis to assess the potential impacts of the alternatives on the supply of recreation opportunities and recreation use and demand.

Other reasonably foreseeable actions include transportation and utility developments proposed by the State of Alaska. These proposals are summarized in the *Transportation and Utilities* section of this document. A total of 1,523 miles of roads are projected to be constructed on non-NFS lands in Southeast Alaska after full implementation of the plan (100+ years) under each of the alternatives (see Table 3.12-3). Most of the projected non-NFS roads are forest roads that would be developed for timber harvest, but the total miles also include roads likely to be built to serve communities, such as the Juneau access road on the east side of Lynn Canal. This road, and other road corridors covered by Public Law 109-59, would, if approved under NEPA and funded, connect additional areas in Southeast Alaska to the continental highway system and improve transportation between communities. They would also improve access for recreation use and would in some cases likely facilitate new types of use.

It is not possible at this time to predict exactly which roads would be developed or their likely impact on future recreation patterns. None of the alternatives is expected to affect this type of future road development, which would be expected to go or not go forward regardless of the selected alternative. The overall cumulative effect of new regional road corridors viewed in conjunction with the proposed Forest Plan alternatives would be a trend toward the roaded end of the ROS spectrum that would be relatively high under Alternative 7 and relatively low under Alternative 1. Planned timber harvest activities on adjacent private and Native corporation lands would also result in a cumulative trend toward more land in roaded ROS settings. This would also be most pronounced under Alternative 7 and least pronounced under Alternative 1.

Other reasonably foreseeable future actions include an expected growth in recreation and tourism businesses based on continued growth in the cruise ship industry, as well as the development of additional fishing and other lodges. This type of development would facilitate additional recreation and tourism in the region and on the Forest. Human settlement expansion is expected to occur around the region's larger cities, such as Juneau and Sitka, with residential expansion also expected as a result of state land auctions. These developments would likely result in increased demand for a range of recreation activities, with some developments favoring developed recreation opportunities, and others more dependent on undeveloped lands.

Mining activities are expected to expand at existing sites, including Greens Creek on Admiralty Island and Berner's Bay north of Juneau, with an increase in mining exploration and new development also anticipated. Regional energy and transmission projects are also expected to occur, including the Swan-Tyee transmission line and the Juneau-Hoonah transmission line. Mining and regional energy projects are for the most part expected to have a negative effect on recreation activities, because most recreational activities are incompatible with these types of land use. Improvements in reliable electrical service could, however, benefit some recreation businesses and, by extension, recreationists.

Risk and Uncertainty

As stated in a number of locations in this section, recreation and tourism in Southeast Alaska and on the Tongass is influenced by a number of factors that are largely independent of forest management decisions. Factors affecting the current level of visitation to the region, for example, likely include the impact of events at the World Trade Center on September 11, 2001, and the relatively weak U.S. dollar, both of which favor domestic over international travel and may have prompted some to take a trip to Southeast Alaska, rather than a trip abroad. Future recreation and tourism demand is difficult to predict with any precision and no attempt is made to quantify future demand in this section. The number of cruise ship visitors to the region is generally expected to remain at current levels or continue to increase, but there is uncertainty that this will be the case for the foreseeable future.

Likely impacts to the supply of recreation opportunities on the Forest are easier to project, as they are directly affected by management decisions, at least to the extent that different LUD classifications influence potential ROS classes and, therefore, different types of recreation. Much of the analysis in this section is based on this relationship, which allows a comparison between alternatives over time.

Changes in Southeast Alaska's climate (discussed in the *Climate and Air* section) could affect recreation and tourism in the region in the future. Many tourists visiting the region travel long distances from across the United States, as well as from other countries. Many tourists arriving by cruise ships travel a considerable distance by air before even boarding the cruise ship in Seattle, Vancouver, or elsewhere. Others travel directly to Southeast Alaska via air. Future regulatory or market-based pressures to reduce transportation-related greenhouse gases could affect the level of visitation to the region.

Recreation activities could also be directly affected by global warming, with, for example, fewer winter recreation opportunities available and for shorter periods of time. Climate change could also affect recreational fishing through changes in biodiversity and water levels, as well as changes in the length of season and user experience (Kelly et al. 2007).

Scenery

Affected Environment

The Tongass National Forest offers a variety of scenery to its visitors, from spectacular mountain ranges and the glaciers of the mainland to low-lying marine landscapes composed of intricate waterways, bays, and island groups. The Forest is viewed from a variety of vantage points, including the communities of Southeast Alaska, the Alaska Marine Highway ferry route, cruise ship routes, existing road systems, popular small boat routes and anchorages, developed recreation sites and facilities, and hiking trails. Tourist-related flight seeing via small aircraft is increasing in popularity and provides aerial views of the forest landscape.

The Forest Service developed a Visual Management System (VMS) in 1974 to integrate aesthetic considerations into large-scale resource management decisions. VMS included objective criteria, such as viewing distance and the degree of visual change to the landscape for estimating the effects of management activities. However, VMS used somewhat subjective definitions of what constituted an aesthetic landscape and relied on professional judgment to quantify effects. The Scenic Management System (SMS) was released in 1996 to integrate the increased understanding of ecosystem processes and cultural landscapes in identifying the effects of various management practices on scenic resources. The SMS was used in this analysis to inventory existing scenic resources, provide measurable scenic quality management objectives for each portion of the landscape, and estimate the landscape's sensitivity based on the visibility from priority travelways and use areas.

In order to apply SMS to the Forest, a viewshed analysis of the entire Tongass National Forest was completed using GIS. The analysis was completed separately for each Ranger District. Step one involved identifying the Visual Priority Routes (VPRs) and use areas. These are the major points from which people view the forest. They include the Alaska Marine Highway; cruise ship and small boat routes; major roads, trails, and anchorages; and important recreation areas on the land. The viewshed analysis identified points at regular intervals along the VPRs and use areas. Each viewpoint along a route was assigned a viewing height from which a person would observe the forest. For example, the average height of a person was selected for the viewing height along a hiking trail, and the height of the cruise ship's deck was used for the cruise ship route. Each cell in the digital elevation model was evaluated for visibility from each of the points along each VPR and use area. Visibility was assessed separately for each marine viewpoint and land viewpoint.

The second phase of the analysis identified distance zones, breaking the visible areas into foreground, middleground, and background from each viewpoint, based on distance. Foreground is the visible area within 0.5 mile of a VPR; background is the visible area greater than 5 miles and less than 15 miles from a VPR; and middleground is the visible area between foreground and background of a VPR. Areas more than 15 miles from any viewpoint and those not seen from any of the VPRs or Use Areas were considered seldom seen. Distance zones were also assessed separately for land and water viewpoints. The final layers for each Ranger District were generated by combining the results from the marine analysis and the land analysis. Any point that was visible from either a land or marine viewpoint was considered visible in the final layer. Any area that was foreground from either a land or marine viewpoint was considered foreground, and any land that was background from either a land or marine viewpoint became background. All other visible land became middleground. The distance zones were subsequently overlaid with the LUDs to generate the Scenic Integrity Objectives (SIOs) (refer to the Forest-wide standards and guidelines in the Tongass Land and Resource Management Plan for details on how SIOs were determined for each LUD).

Existing Scenic Integrity

The existing scenic resources of the Tongass encompass everything from vast tracts unmodified by human activity to extensive areas of heavily modified landscapes. Existing Scenic Integrity (ESI) ratings are used by the Forest Service to analyze the degree of intactness of the landscape character. These ratings are used to categorize the degree of alteration visible in the landscape on a continuum from a natural setting to a heavily altered landscape. The ratings apply to the broad landscape affected, not just the acres altered. As described below, ESI ratings range over six levels of integrity, from Very High to Unacceptably Low.

- Very High—Landscapes where the valued landscape character is intact with only minute deviations, if any. The existing landscape character and sense of place is expressed at the highest possible level.
- High—Landscapes where the valued landscape character appears intact. Deviations may be present, but must repeat the form, line, color, texture, and pattern common to the landscape character so completely and at such scale that they are not evident.
- Moderate—Landscapes where the valued landscape character appears slightly altered. Noticeable deviations must remain visually subordinate to the landscape character being viewed.
- Low—Landscapes where the valued landscape character appears moderately altered. Deviations begin to dominate the valued landscape character being viewed, but they borrow valued attributes such as size, shape, edge effect and pattern of natural openings, vegetative type changes or architectural styles outside the landscape being viewed. They should not only appear as valued character outside the landscape being viewed, but compatible or complimentary to the character within.
- Very Low—Landscapes where the valued landscape character appears heavily altered. Deviations may strongly dominate the valued landscape character. They may not borrow from valued attributes such as size, shape, edge effect and pattern of natural openings, vegetative type changes, or architectural styles within or outside the landscape being viewed.
- Unacceptably Low—Landscapes where the valued landscape character being viewed appears extremely altered. Deviations are extremely dominant and borrow little if any form, line, color, texture, pattern or scale from the landscape character.

Table 3.16-1 displays the acres of each ESI for the Tongass. In this and succeeding tables, a breakdown between “seen” and “seldom seen” areas is presented. Seen areas are those areas that can be viewed in the foreground, middleground, or background from inventoried VPR and Use Areas with a concern level of 1 or 2, the travelways and use areas with the highest number of users. Seldom seen areas are all the rest of the Forest. The ESI for wilderness is also included in this table. Approximately 88 percent of the Tongass is rated as a Very High ESI, which is a visually unaltered condition. About 10 percent of the land is rated in as Low, Very Low, or Unacceptably Low, which indicates noticeable development activity. The remainder of the Forest is rated as High or Moderate. Some of the wilderness acres have a High or lower rating. This is mostly due to the landscape effect of developments adjacent to wilderness and past development activities within wildernesses.

Table 3.16-1
The Existing Scenic Integrity of the Tongass National Forest (percent)

ESI Rating	Very High/High	Moderate	Low	Very Low	Unacceptably Low
Seen	23.6	1.2	1.6	3.4	0.1
Seldom seen	30.5	0.2	1.4	3.4	0.1
Wilderness	30.2	0.1	0.1	-	-
Subtotals	**88.3**	**1.5**	**3.1**	**6.8**	**0.2**

Note: Numbers are GIS estimates and are not exact. Columns and rows may not sum exactly due to rounding. Less than 2 percent of the Forest is unclassified.

Under the 1997 Forest Plan, all land has a designated Land Use Designation (LUD), which guides the types and intensity of development actions. The LUDs designate the SIOs for each area, which define the degree to which the natural landscape can be altered, and provide guidelines for timber harvest, road building, and other activities to ensure they are conducted in a way that allows the scenic objectives to be achieved. A LUD may have different SIOs depending on the distance zone (foreground, middleground, background) in which the development activity is to take place. SIOs are classified using the same terms outlined above for ESI: Very High, High, Moderate, Low, and Very Low. The Unacceptably Low rating is only used to inventory existing conditions and cannot be used as a management objective.

1. The current adopted SIOs for all land within the Tongass are displayed in Table 3.16-2. This table separates the acres of each SIO into five categories: foreground, middleground, background, seldom seen, and other (municipal watersheds and non-wilderness national monuments where the SIO is determined on a project-by-project basis). The Very High SIO is typically assigned to wilderness; however, it is not used for Tongass wilderness because of the potential alterations allowed under the Alaska National Interest Lands Conservation Act (ANILCA). In reality, the vast majority of wilderness acreage will be managed through the specific wilderness plans with a Very High SIO. Thus, over 60 percent of the Tongass is to be managed at the High or Very High Scenic Integrity level.

2. Demand for scenic quality can best be represented by the increase in tourist-related travel to the Tongass, as well as a heightened awareness and sensitivity of Alaskan residents to scenic resource values. Southeast Alaska's Inside Passage is advertised and promoted by the Division of Tourism, cruise ship operators, and the Southeast Alaska Tourism Council. Their marketing strategy focuses on the scenery of the Tongass National Forest as a major attraction. The visitors to Southeast Alaska would, therefore, arrive with expectations and an image of the environment and scenery awaiting them. If current trends continue, demand for viewing scenic landscapes will increase. Studies published by the Alaska Department of Community and Economic Development show a 62 percent increase in visitor

Table 3.16-2
Adopted Scenic Integrity Objectives for the Tongass (percent)

	Visual Quality Objective				
	High	**Moderate**	**Low**	**Very Low**	**Other[1]**
Foreground	8.0	3.7	1.6	-	0.2
Middleground	24.2	9.3	2.2	8.0	0.3
Background	1.6	0.6	-	0.4	-
Seldom seen	25.9	6.3	-	5.7	0.7
Unmapped	1.1	0.3	-	-	-
Total	**59.7**	**19.9**	**3.8**	**14.1**	**1.2**

[1] Includes land in the Municipal Watershed and Nonwilderness National Monument LUDs. SIOs in these LUDs are to be determined on a project-by-project basis. Generally, the High SIO will be met.
Source: USDA Forest Service, GIS. Numbers are not exact and may not sum correctly due to rounding.

arrivals to Alaska since 1993. Lands adjacent to the Alaska Marine Highway, cruise ship routes, flight-seeing routes, high-use recreation areas, and other marine and land-based travel routes will be seen by more people, more frequently, and for greater duration.

Environmental Consequences

The Tongass has adopted specific management objectives for scenic resources (SIOs) for each LUD in the Forest. The adopted SIOs indicate the desired or acceptable level of human-induced alteration to the valued landscape character. Each alternative described in this FEIS would, if implemented, maintain, alter, or enhance the visual character of the landscape to varying degrees, depending on the mix of LUDs in that alternative. By varying the amount of land in each LUD, the alternatives would result in different amounts of land managed under each SIO. The adopted SIO is, therefore, the unit used to measure potential change in visual resources for each alternative.

Adopted SIOs can be thought of as an indicator of long-term cumulative effects, especially on development LUDs. SIOs are adopted to provide a threshold for the amount of modification to the landscape during land altering activities; therefore, land may have an adopted SIO of Low, but currently meet the High SIO.

The potential effects to the scenic resource are described in the following three ways:

1. A Forest-wide display of acres of each SIO adopted as a result of each alternative.
2. A display of the number of acres within the three development LUDs that would be suitable for timber harvest under each alternative. The acres suitable for harvest are listed by their location within the foreground, middleground, background, or seldom seen area.
3. A display of the effects of each alternative on a selected group of viewsheds throughout the Tongass.

Direct, Indirect, and Cumulative Forest-wide Effects

Table 3.16-3 displays the acres in each SIO that would result from the seven alternatives. Table 3.16-3 also shows the acres under each alternative and SIO that would be located within seen and seldom seen areas. Seen areas are those areas

[1] Consists of land in the municipal Watershed and Nonwilderness National Monument LUDs. SIOs in these LUDs are to be determined on a project-by-project basis. Generally, the High SIO will be met.
[2] Consists of unmapped portions of the Forest.
Note: Numbers are based on GIS estimates and are not exact due to rounding.

that can be viewed in the foreground, middleground, or background from inventoried travelways and use areas. Wilderness areas are included in these acreages. The acres displayed for Alternative 5 (No Action) represent the current mix of adopted SIOs.

The number of acres designated as High SIO would be similar under all alternatives except Alternatives 4 and 7, which have fewer acres in the High SIO category (56 and 54 acres, respectively, compared to 61 percent under Alternative 5). However, the area with an SIO of Low or Very Low would vary considerably between alternatives, especially within the seen areas. The acres of Low or Very Low SIO in the seen area under Alternative 1 would be approximately 3 percent of the Tongass, compared to 12 percent under Alternative 5. Conversely, the seen area with an SIO of Low or Very Low under Alternatives 4 and 7 would be approximately 16 and 17 percent, respectively. Alternatives 2 and 3 would be between Alternatives 1 and 5 in terms of the amount of seen area with an SIO of Low or Very Low. Alternative 6 would result in a mix of SIOs that would be similar to Alternative 5.

Another way to assess the relative effects of the alternatives on scenic integrity is to compare the area under each alternative that would be suitable for timber harvest.

The percent of land that is suitable for timber harvest within the three development LUDs (Scenic Viewshed, Modified Landscape, and Timber Production) under each alternative is shown in Table 3.16-4. The table indicates the amount of land suitable for timber harvest within the foreground, middleground, and background as seen from high priority travel routes and use areas. The percent of suitable land within seldom seen areas is also shown.

Under all the alternatives, approximately two-thirds of the suitable lands for timber harvest are within the Timber Production LUD. The number of suitable acres allocated to this LUD varies from approximately 312,000 acres under Alternative 1 to approximately 1,174,000 under Alternative 7. This compares to approximately 781,000 under Alternative 5 (No Action). Although all harvest units would meet the SIO for the individual distance zone and LUD, the degree of change to the visual resources are likely to be the greatest in the Timber Production LUD. Approximately one-half of the suitable acres allocated to Timber Production would be in seen areas.

Alternative 1. Under Alternative 1, approximately 62 percent of the Forest would have an adopted SIO of High and would be managed for a Natural Setting (Table 3.16-3). This is similar to Alternative 5 (No Action), which would have 61 percent with an SIO of High. Areas with a High SIO are managed so that the valued landscape character appears intact. As is the case with all the alternatives, over one-half of the land with the High SIO would be within Wilderness or National Monument LUDs. Approximately 32 percent of the Forest under Alternative 1 would have a Moderate SIO. Landscapes with this SIO are managed to achieve a mostly natural condition. This alternative has the highest acreage designated as High and Moderate SIO. Most of the remaining Forest lands (6 percent) would have an adopted SIO of Low or Very Low (compared to approximately 18 percent under Alternative 5). Areas with these SIOs are managed so that the valued landscape character would appear moderately or heavily altered.

This alternative has the least amount of land suitable for timber harvest compared to the other alternatives. Alternative 1 would have less than one-half the suitable acres as Alternative 5 (No Action). Approximately 7 percent of the suitable acres would be designated Scenic Viewshed, 22 percent Modified Landscape, and 71 percent Timber Production LUD (the LUD projected to have the greatest degree of change) (Table 3.16-4). Alternative 1 would result in the least amount of new road construction (approximately 1,766 miles) over the next 10 decades.

Table 3.16-4
Distance Zone breakdown of the Estimated Suitable Forest Land for Each Alternative by Development LUD

	Alternatives						
	1	**2**	**3**	**4**	**5**	**6**	**7**

Note: Numbers are based on GIS estimates and are not exact. Columns do not sum correctly due to rounding.

Alternative 2. The overall distribution of adopted SIOs would be similar to those under Alternative 1 (Table 3.16-3), except that there would be fewer acres in the Moderate SIO (27 percent compared to 32 percent under Alternative 1 and 19 percent under Alternative 5) and more in the Low and Very Low SIOs (9 percent compared to 4 percent for Alternative 1). This alternative has approximately one-third more suitable land than Alternative 1. Alternative 2 has slightly more acres of suitable lands for timber harvest in the Scenic Viewshed LUD than Alternative 1, and more of these lands are in the foreground, which is the area likely to have the least change in the visual condition (Table 3.16-4). Alternative 2 would result in approximately 2,600 miles of new road construction over the next 10 decades.

Alternative 3. Alternative 3 would have more acres in the development LUDs than Alternatives 1 and 2, but there would be only a slight decrease in the amount of land in the High SIO (61 percent versus 62 percent under Alternatives 1 and 2). This is due primarily to allocating more land to the Scenic Viewshed LUD, in which the foreground lands are managed as High SIO (Table 3.16-3). There would be less land in the Moderate SIO than Alternatives 1 and 2, but more than under

Alternatives 4, 5, 6, or 7. More land would have Low and Very Low SIOs compared to Alternatives 1 and 2 (slightly over 14 percent compared to 4 and 9 percent, respectively). Alternative 3 would have more suitable land for timber harvest than Alternatives 1 or 2 (Table 3.16-4). Alternative 3 would result in approximately 3,464 miles of new roads over the next 10 decades.

Alternative 4. Alternative 4 would have more acres in development LUDs than Alternative 5 and less land in the High SIO (nearly 56 percent compared to 62 percent under Alternative 1 and 61 percent under Alternative 5). Alternative 4 would have more land in Low and Very Low SIOs (23 percent compared to 4 percent under Alternative 1 and 18 percent under Alternative 5). Alternative 4 would have more suitable land for timber harvest than Alternative 5 and more acres in the Timber Production LUD. Alternative 4 would result in approximately 5,487 miles of new road construction over the next 10 decades.

Alternative 5. Alternative 5, the No-Action Alternative, would have approximately 61 percent of the land in the High SIO, which is similar to Alternatives 1, 2, 3, and 6 (Table 3.16.3). This alternative would have a relatively low percentage of land suitable for harvest in the foreground (18 percent), compared to 25 percent under Alternative 1. A relatively high percent of the suitable lands (20 percent) would be within the seldom seen areas. Alternative 5 would result in approximately 4,351 miles of new roads over the next 10 decades.

Alternative 6. Alternative 6, the Proposed Action, is very similar to Alternative 5 in terms of its effect on the visual resource. The mix of SIOs would be nearly the same under Alternative 6 as it would be under Alternative 5. Alternative 6, along with Alternative 5, would have a relatively high percentage of land in the seldom seen areas. Alternative 6 would result in approximately 4,285 miles of new roads over the next 10 decades, which is slightly less than under Alternative 5.

Alternative 7. Alternative 7 would have the most acres in development LUDs of all the alternatives and the least land in the High SIO (nearly 54 percent compared to 62 percent under Alternative 1 and 61 percent under Alternative 5). Alternative 7 would have the most land in Low and Very Low SIOs (nearly 25 percent compared to 4 percent under Alternatives 1 and 18 percent under Alternative 5). Alternative 7 would have more suitable land for timber harvest than Alternative 5 (over 3 times as much as Alternative 1 and approximately 50 percent more than Alternative 5) and more acres in the Timber Production LUD. Alternative 7 would result in the highest amount of new road construction (approximately 6,264 miles) over the next 10 decades.

Effects on Selected Viewsheds

To help focus the visual effects on more familiar areas, the alternatives were also analyzed by selected viewsheds in the Tongass. These viewsheds were selected for their popularity and intensity of public use and travel. Table 3.16-5 compares the amount of land in each SIO under the six alternatives for each of the viewsheds from these selected routes. Discussion of the effects on scenic resources for each viewshed follows the table.

Two points to consider when reviewing the alternative effects are:

1. Where an area is allocated to the Semi-remote Recreation LUD, the formally adopted SIO is Moderate; however, the resulting SIO is essentially High because this LUD precludes commercial timber harvest. The Moderate SIO is primarily intended to provide a standard for recreation and tourism types of development and facilities associated with these developments, from small

[1] VQO terms are defined in the *Affected Environment* portion of this section.
[2] The percentages in the table are based on the approximate acres seen from a Visual Priority Travel Route and Use Area. The numbers are not exact and columns may not add correctly due to rounding.
[3] Other includes private lands, municipal watersheds, and National Monuments.

cabins to resorts. In most cases, the effects would be confined to small sites that would be inconspicuous over a landscape. Therefore, much of the area identified as Moderate would be managed as High.

2. The Tongass adopts the High SIO for wildernesses rather than Very High because of the direction in ANILCA; however, the Very High SIO is likely to be achieved in most areas within wilderness.

Behm Canal (West)

Alternatives 4 and 7 would each adopt an SIO of High for approximately 6 percent of the viewshed and an SIO of Low or Very Low for 75 percent of the viewshed (Table 3.16-5). This compares to Alternative 1 which would manage 16 percent with an SIO of High and 36 percent of the viewshed with an SIO of Low or Very Low. Therefore, Alternatives 4 and 7 would have the greatest effect on scenery in the Behm Canal Viewshed, while Alternative 1 would have the least. Effects on scenery under Alternatives 2, 3, 5, and 6 would be intermediate, with 19 to 21 percent managed with an SIO of High and 60 to 61 percent Low or Very Low. In some areas, particularly on the Revella Island side of the Canal, existing harvest has reached or exceeded the level allowed by the adopted SIOs. Additional harvest may need to be reduced or deferred in these areas in the coming decade.

Carroll Inlet

Alternatives 4 and 7 would manage approximately 81 percent of the viewshed with an SIO of Low or Very Low and almost none of it with a High (Table 3.16-5). This compares to Alternative 1 which would manage 14 percent in High and 36 percent in Low or Very Low. Alternatives 2, 3, 5, and 6 have similar distribution of LUDs and thus would result in similar SIO designations, with approximately 12 to 14 percent of the land with an SIO of High and 68 percent with an SIO of Low or Very Low. Therefore, Alternatives 4 and 7 would likely result in the highest level of change in visual condition of the alternatives and Alternative 1 would have the least. Effects on scenery under Alternatives 2, 3, 5, and 6 would be intermediate.

Chatham Strait

Under all of the alternatives except Alternatives 4 and 7, 56 to 59 percent of the Chatham Strait Viewshed would be managed as High SIO (Table 3.16-5). Under Alternatives 4, approximately 47 percent of the viewshed would have an SIO of High and under Alternative 7, 39 percent. Under Alternative 1, 11 percent of the viewshed would be managed with an SIO of Low or Very Low. This compares with 25 percent under Alternative 2, between 35 and 43 percent for Alternatives 3, 4, 5, and 6, and 50 percent for Alternative 7. Therefore, Alternative 7, followed by Alternative 4, would result in the greatest level of change. In some areas, particularly between Peril Strait and Tenakee Inlet, where existing harvest has reached or exceeded the level allowed by the adopted SIOs. Additional harvest may need to be reduced or deferred in these areas in the coming decade.

Cholmondeley Sound

Approximately 90 percent of the viewshed would have an SIO of Low or Very Low under Alternatives 4 and 7, compared to 2 percent under Alternative 1 (Table 3.16-5). Alternatives 2, 3, 5, and 6 would result in 55 to 60 percent in Low or Very Low SIOs. Between 35 and 39 percent of the viewshed would have a High SIO under all alternatives except Alternatives 4 and 7, which would manage 4 percent under a High SIO. Alternatives 4 and 7 would have a much greater effect on scenery than the other alternatives. Alternative 1 would have a much lower level of effects than Alternatives 4 and 7. Effects on scenery under Alternatives 2, 3, 5, and 6 would be intermediate. Under all of the alternatives, most of the outer part of the bay would be in an extensively altered condition due to harvest on private lands.

Clarence Strait

Clarence Strait is a large viewshed, extending along both sides of the strait from its northern end south to Gravinia Island. The viewshed includes portions of the South Etolin Wilderness Area, which would have an SIO of High under all alternatives. While the wilderness has a designated SIO of High, a Very High SIO would likely be achieved. All alternatives except Alternatives 4 and 7 would adopt an SIO of High for 44 to 46 percent of the viewshed (Table 3.16-5). Alternative 4 would adopt an SIO of High for 34 percent of the viewshed, while Alternative 7 would adopt an SIO of High for 22 percent. Alternatives 3, 5, and 6 would result in approximately 34 percent Low or Very Low SIO, compared to 15 percent under Alternative 1 and 28 percent under Alternative 2. Approximately 46 percent of the viewshed would be Low or Very Low under Alternative 4 and 53 percent would be Low or Very Low under Alternative 7. Therefore, Alternative 7 would result in the highest level of change to the viewshed, while Alternative 1 would result in the least. Effects on scenery under Alternatives 2, 3, 5, and 6 would be midway between the two, with slightly lower effects under Alternative 2 than under Alternatives 3, 5, and 6. Effects Under Alternative 4 would be similar, but somewhat lower, than under Alternative 7.

Duncan Canal

All of the alternatives except Alternatives 4 and 7 would adopt an SIO of High for approximately between 18 and 21 percent of the viewshed (Table 3.16-5), due primarily to the Old-Growth LUD located along both sides of the southern end of Duncan Canal. Alternatives 4 and 7 would have 9 and 1 percent High, respectively. Alternatives 5 and 6 would designate 61 to 64 percent as Low or Very Low SIO. Alternatives 2 and 3 would adopt an SIO of Low or Very Low for 28 percent of the viewshed. Alternatives 4 and 7 would have 74 and 78 percent Low or Very Low, respectively, and thus would have the greatest effect on scenery in the viewshed. Alternative 1 would have the least, closely followed by Alternatives 2 and 3. Alternatives 5 and 6 would result in a greater level of change than Alternatives 1, 2 or 3, but a lower level than Alternatives 4 or 7.

Eastern Passage

All alternatives except Alternatives 4 and 7 would adopt an SIO of High for 15 to 19 percent of the viewshed, versus 11 percent under Alternative 4 and 9 percent under Alternative 7 (Table 3.16-5). Alternatives 1 and 2 would adopt an SIO of Low or Very Low for 7 and 16 percent of the viewshed, respectively, compared to 30 percent under Alternatives 3, 4, 5, 6, and 7 (Table 3.16-5). Therefore, Alternatives 1 and 2 would likely result in less change to the visual condition of the viewshed compared to the other alternatives. Alternatives 4 and 7 would likely have a somewhat greater effect on scenery than Alternatives 3, 5, and 6.

Ernest Sound

Under all of the alternatives except Alternatives 4 and 7, 29 or 30 percent of the viewshed would be managed as High SIO (Table 3.16-5), due to the Old-Growth LUD located on the northwestern shore of Cleveland Peninsula. Approximately 23 and 2 percent would have a High SIO under Alternatives 4 and 7, respectively. There would be no Low or Very Low SIOs under Alternatives 1 and 2, compared to 33 percent under Alternative 3, and 59 or 60 percent under Alternatives 5 and 6. Alternatives 4 and 7 would designate 65 and 86 percent as Low or Very Low, respectively. Therefore, Alternatives 1 and 2 would likely result in less change to the visual condition of the viewshed compared to the other alternatives. Alternative 7 would likely have the greatest effect on scenery, and Alternative 4 would likely have the second largest effect after Alternative 7.

Frederick Sound

All of the alternatives except Alternatives 4 and 7 would adopt an SIO of High for approximately 21 to 25 percent of the Frederick Sound Viewshed (Table 3.16-5). Most of the High SIO occurs within a large area of Old-Growth LUD on the northeast shore of Kupreanof Island, as well as several smaller Old-Growth LUDs along the eastern shore of Kupreanof and Mitkof islands. Under Alternatives 4 and 7, approximately 14 and 6 percent would have an SIO of High, respectively. Alternative 4 would adopt an SIO of Low or Very Low for 64 percent of the viewshed, compared to 52 to 47 percent for Alternatives 5 and 6, respectively, 41 percent for Alternative 3, 26 percent for Alternative 2, and 71 percent for Alternative 7. Alternative 1 would adopt an SIO of Low or Very Low for 12 percent of the viewshed, approximately one-sixth the Low and Very Low under Alternative 7 (Table 3.16-5). Alternative 1 would have the least effect on scenery in the viewshed, and Alternatives 4 and, especially, 7 would have the greatest effect on scenery in the viewshed. The other alternatives would be intermediate.

Hyder/Salmon River

All alternatives would all have a moderate effect on scenery in the Hyder/Salmon River viewshed (Table 3.16-5). Alternatives 4 and 7 would likely have a somewhat greater effect on scenery in the viewshed than the other alternatives because they would adopt a Low or Very Low SIO for 25 percent of the viewshed, compared to 0 to 6 percent under Alternatives 1, 2, 3, 5, and 6.

Icy Strait

All of the alternatives except for Alternatives 4 and 7 would adopt an SIO of High for between 47 and 49 percent of the viewshed (Table 3.16-5), due partly to the Wilderness LUDs on Pleasant and Lemesurier Islands and the LUD II and Old-Growth LUD at Point Adolphus. Wilderness areas would have an SIO of High under all alternatives, but would likely achieve an SIO of Very High. The amount of the viewshed with an SIO of High would drop to 27 to 26 percent under Alternatives 4 and 7, respectively. Alternatives 2, 3, 5, and 6 would all adopt an SIO of Low or Very Low for 29 to 30 percent of the viewshed, compared to 7 percent for Alternative 1 and 47 to 48 percent for Alternatives 4 and 7. Alternatives 4 and 7 would have the greatest effect on scenery in the viewshed, while Alternative 1 would have the least. There would be little difference between the other alternatives, which would have effects midway between Alternative 1 and Alternatives 4 and 7. Under all of the alternatives, much of the south shore of the strait would be in an altered condition due to harvest on private lands.

Lynn Canal

Scenic effects within the Lynn Canal Viewshed would be very similar under all of the alternatives (Table 3.16-5). All alternatives would adopt an SIO of High for approximately one-third of the viewshed, due primarily to the large Remote Recreation LUD on the east side of Lynn Canal. All of the alternatives would have relatively low percentages of land with an SIO of Low or Very Low, with less than 2 percent for Alternatives 1 and 2 and 9 percent for Alternatives 3, 5, and 6. Alternatives 4 and 7 would have 11 to 12 percent of land with a Low or Very Low SIO (Table 3.16-5). Therefore, while all alternatives would have a moderate effect on scenery in the viewshed, Alternatives 1 and 2 would result in a somewhat lesser change to the scenery that the other alternatives.

Mendenhall Glacier

The effects of all of the alternatives on the Mendenhall Glacier Viewshed are similar for all alternatives except Alternative 5 (Table 3.16-5). Over half the viewshed would have an SIO of High, while the remainder would be Moderate under Alternative 5 (No Action). In contrast, all of the action alternatives would adopt an SIO of High for 34 percent of the viewshed and a Moderate for 66 percent (Table 3.16-5). All the alternatives have a large Remote Recreation LUD located north of Taku Inlet, with most of the remaining viewshed designated as Semi-Remote Recreation. Under Alternative 5, the Remote Recreation LUD is larger, extending further to the west, resulting in 55 percent of the viewshed managed as High SIO, compared to 34 percent for the other alternatives. As noted above, Semi-Remote Recreation LUDs generally achieve an SIO of High, making Alternative 5 almost identical to the other alternatives in terms of effects on scenery.

Peril Strait/Neva-Olga Strait/Sitka

Approximately 35 and 42 percent of the viewshed would be have an SIO of High under all alternatives except Alternatives 4 and 7, which would adopt an SIO of High for 16 and 12 percent of the viewshed, respectively (Table 3.16-5). Approximately three-fourths of the viewshed would have an SIO of Low or Very Low under Alternatives 4 and 7, compared to 0 percent for Alternative 1, 25 percent for Alternative 2, 28 percent for Alternative 3, 47 percent for Alternative 5, and 44 percent under Alternative 6. Therefore, the effects on scenery would be lowest under Alternative 1, followed by Alternatives 2 and 3, and then Alternatives 5 and 6. The level of change would be greatest under Alternatives 4 and 7. Existing harvest in a few areas (particularly the Sitkoh Bay/False Island areas) may have reached or exceeded the level allowed by the adopted SIOs. Site-specific analysis may indicate that even-aged harvest may need to be reduced or deferred in these areas for the next decade.

Salmon Bay Lake
Between 38 and 41 percent of the viewshed would have an SIO of High under all alternatives except Alternative 7, which would adopt an SIO of High for 4 percent of the viewshed (Table 3.16-5). Alternatives 1, 2, and 3 would adopt an SIO of Low or Very Low for 21 to 25 percent of the viewshed, Alternatives 4, 5, and 6 would adopt an SIO of Low or Very Low for 40 to 41 percent of the viewshed, and Alternative 7 would adopt an SIO of Low or Very Low for 57 percent, and would have the greatest effect on scenery in the viewshed.

Stephens Passage
All of the alternatives except Alternatives 4 and 7 would adopt an SIO of High for 38 to 40 percent of the viewshed (Table 3.16-5), due in part to the Wilderness/National Monument LUDs, which include portions of the Admiralty Island National Monument and the Tracy Arm Ford's Terror Wilderness Area. These areas would have an SIO of High under all alternatives but would likely achieve an SIO of Very High. Alternatives 4 and 7 would adopt an SIO of High for 31 percent of the viewshed. Alternatives 1 to 3 would adopt an SIO of Low or Very Low for between 0 and 3 percent of the viewshed, while Alternatives 4, 5, 6, and 7 would have between 21 and 25 percent. Alternatives 4 and 7, followed closely by Alternatives 5 and 6, would have the greatest effect on scenery, while Alternatives 1 to 3 would have the least.

Stikine Strait
All alternatives except Alternatives 4 and 7 would adopt an SIO of High for between 28 and 38 of the viewshed (Table 3.16-5). Alternatives 4 and 7 would adopt an SIO of High for 13 percent. Alternative 1 would adopt an SIO of Low or Very Low for 14 percent of the viewshed, while Alternatives 3, 5, and 6 would have 33 percent and Alternatives 4 and 7 would have 42 percent. Therefore, Alternative 1 would have the least effect on scenery, and Alternatives 4 and 7 would have the most; Alternatives 3, 5, and 6 would have an intermediate level of effects on scenery.

Sumner Strait
The Sumner Strait Viewshed includes portions of the Kuiu Wilderness and the Mt. Calder/Mt. Holbrook and Salmon Bay LUD II areas. These areas would have an SIO of High under all alternatives but would likely achieve an SIO of Very High. All alternatives except Alternatives 4 and 7 adopt an SIO of High for between 30 and 31 percent of the Viewshed (Table 3.16-5). Alternatives 4 and 7 would adopt an SIO of High for 23 and 21 percent, respectively. Alternatives 4 and 7 would adopt an SIO of Low or Very Low for between 68 and 69 percent of the viewshed, compared to 50 to 51 percent for Alternatives 5 and 6, 39 percent for Alternative 3, and 17 to 22 percent for Alternatives 1 and 2 (Table 3.16-5). Therefore, Alternatives 4 and 7 would have the greatest effect on scenery and Alternative 1 would have the least, closely followed by Alternative 2, and then by Alternatives 3, 5, and 6, in that order.

Sweetwater Lake/Honker Divide
All alternatives except Alternative 4 and 7 would adopt an SIO of High for between 63 and 69 percent of the viewshed (Table 3.16-5). Alternatives 1, 2, and 3 would adopt an SIO of Low or Very Low for between 14 and 17 percent of the viewshed, while Alternatives 5 and 6 would adopt an SIO of Low or Very Low for 21 percent of the viewshed. Alternative 4 would adopt an SIO of High for 50 percent and an SIO of Low or Very Low for 32 percent. Alternative 7 would adopt an SIO of High for 21 percent of the viewshed and a Low or Very low for 49 percent. Therefore,

Alternative 7 would have the greateest effect on scenery in the viewshed, while Alternatives 1, 2, and 3 would have the least, followed closely by Alternatives 5 and 6. Effects under Alternative 4 would be between those under Alternatives 5 and 7.

Tenakee Inlet to Tenakee Springs

This viewshed contains the Trap Bay and Kadashan LUD II areas, which have an SIO of High under all alternatives (Table 3.16-5). The viewshed also contains land designated as Research Natural Area and Wild River LUDs, which also have a High SIO under all alternatives. Alternatives 1, 2, and 3 would adopt an SIO of High for between 76 and 82 percent of the viewshed and an SIO of Low or Very Low for between 4 and 24 percent of the viewshed, while Alternatives 5 and 6 would adopt an SIO of High for 33 to 40 percent and an SIO of Low or Very Low for 66 and 42 percent, respectively. Alternative 4 would adopt an SIO of High for 21 percent and an SIO of Low or Very Low for 76 percent. Alternative 7 would have the least area with an SIO of High (18 percent) and 80 percent with an SIO of Low or Very Low. Therefore, Alternative 7 would have greatest effect on scenery in the viewshed, while Alternative 1 would have the least, followed closely by Alternative 2 and then by Alternative 3.

West Coast Waterway/Prince of Wales
