This viewshed contains the Mt. Calder/Mt. Holbrook LUD II area, which would have an SIO of High under all alternatives. All alternatives except Alternatives 4 and 7 would adopt an SIO of High for between 32 and 38 percent of the viewshed, while Alternatives 4 and 7 would adopt an SIO of High for 27 and 17 percent, respectively (Table 3.16-5). Alternatives 2, 3, 5, and 6 would adopt an SIO of Low or Very Low for between 38 and 49 percent of the viewshed. Alternative 1 would have 23 percent of the viewshed in the Low and Very Low SIOs. Alternative 4 would adopt an SIO of Low or Very Low for 63 percent of the viewshed and Alternative 7 for 72 percent. Therefore, Alternative 7 would have a greatest effect on scenery in the viewshed, while Alternative 1 would have the least. Alternatives 2, 3, 5, and 6 would be midway between Alternatives 1 and 7 in terms of the degree of change to scenery in the viewshed, while Alternative 4 would be close to Alternative 7.

Wrangell Narrows

All alternatives except Alternative 7 would adopt an SIO of High for between 30 and 38 percent of the viewshed (Table 3.16-5). Alternative 7 would adopt an SIO of High for 20 percent of the viewshed. Alternative 1 would adopt an SIO of Low or very Low for 10 percent of the viewshed, compared to between 19 and 27 percent for the other alternatives. Alternative 7 would have a somewhat greater effect than the other alternatives. A small portion of the viewshed would be in the Petersburg Municipal Watershed LUD where SIOs would be determined on a case-by-case basis for any projects proposed in the watershed.

Zimova Strait

All alternatives except Alternatives 4 and 7 would adopt an SIO of High for 39 to 42 percent of the viewshed (Table 3.16-5). Alternatives 4 and 7 would adopt an SIO of High for 22 and 20 percent of the viewshed, respectively. Alternative 1 would have the least land with an SIO of Low or Very Low (19 percent). Alternatives 2, 3, 5, and 6 would designate 31 to 39 percent as Low or Very Low, compared to 44 to 45 percent for Alternatives 4 and 7. Alternative 1 would have the least effect, followed by Alternatives 2, 3, 5, and 6, which are very similar. Alternatives 4 and 7 would have the greatest effect.

Subsistence

Affected Environment

Subsistence hunting, fishing, trapping, and gathering activities are a major focus of life for many Southeast Alaska residents. Some individuals participate in subsistence activities to supplement personal income and provide needed food. Nearly all rural Alaska communities depend on subsistence resources to meet some portion of their nutritional needs (Wolfe 2000). Others pursue subsistence activities to perpetuate cultural customs and traditions. Still others participate in subsistence activities for reasons unconnected with income or tradition. For all these individuals, subsistence is a lifestyle reflecting deeply held attitudes, values, and beliefs.

Within the context of Southeast Alaska's seasonal and cyclical resource-based employment, subsistence harvest of fish and wildlife resources takes on special importance. The use of these resources may play a major role in supplementing cash incomes during periods when the opportunity to participate in the wage economy is either marginal or nonexistent. Because of high prices of commercial products provided through the retail sector of the cash economy, especially in remote communities, the economic role of locally available fish and game takes on added importance.

Native and non-Native communities both have high subsistence participation rates and rely heavily on wild foods, with approximately 86 percent of rural Alaska households using wild game and 95 percent using fish (Wolfe 2000). The opportunity to participate in subsistence activities reinforces a variety of cultural and related values in both Native and non-Native communities. For example, the distribution of harvested fish and wildlife contributes to the cohesion of kinship groups and community stability through the sharing of resources. Subsistence resources provide the foundation for Native culture, forming the basis for different clans and potlatch ceremonies, as well as reinforcing basic values of respect for the earth and its resources. Participating in subsistence activities contributes to the self-reliance, independence, and ability to provide for oneself; values that social surveys indicate are important reasons why many non-Native people emigrate to or remain in Southeast Alaska (USDA Forest Service 1997a).

The Legal Context for Subsistence Use

While there are a variety of cultural, popular, and sociological definitions and interpretations of subsistence, Congress addressed this subject in Title VIII of the 1980 Alaska National Interest Lands Conservation Act (ANILCA). Section 803 of ANILCA defines subsistence use as:

> "the customary and traditional uses by rural Alaska residents of wild renewable resources for direct, personal, or family consumption as food, shelter, fuel, clothing, tools, or transportation; for the making and selling of handicraft articles out of non-edible byproducts of fish and wildlife resources taken for personal or family consumption; for barter, or sharing for personal or family consumption; and for customary trade."

ANILCA provides for "the continuation of the opportunity for subsistence uses by rural residents of Alaska, including both Natives and non-Natives, on the public lands." It also states, in part, that "customary and traditional" subsistence uses of renewable resources "shall be the priority consumptive uses of all such resources on the public lands of Alaska."

The provisions in ANILCA established a harvest priority for rural residents in an attempt to protect subsistence resource harvest. Under ANILCA, in times of resource scarcity or when demand exceeds biologically sound harvest levels, subsistence harvests have priority over other consumptive use of resources. In practice, this meant that commercial, sport, or other harvests were to be curtailed by state or federal fish and wildlife management authorities before subsistence harvests were limited. The Alaska legislature subsequently passed a regulation to comply with ANILCA, but in 1989, the Alaska Supreme Court ruled in McDowell v. State of Alaska that a harvest priority for rural residents conflicted with the state constitution, which guarantees all Alaskans equal access to the state's natural resources. This ruling took the state out of compliance with ANILCA and the federal government has managed subsistence resources on federal lands in Alaska since 1990. As a result, subsistence harvests of fish and wildlife on the Tongass National Forest are presently managed by the Forest Service (Schroeder and Mazza 2005).

ANILCA requires the analysis of the potential effects on subsistence uses of all actions on federal lands in Alaska. This analysis most commonly focuses on those food-related resources most likely to be affected by habitat degradation associated with land management activities. Three factors related to subsistence uses are specifically identified by ANILCA: 1) resource distribution and abundance, 2) access to resources, and 3) competition for the use of resources. These factors are discussed in general terms in the following paragraphs.

Abundance and Distribution

Southeast Alaska subsistence resources include terrestrial wildlife (including deer, moose, mountain goat, black and brown bear, furbearers, and small game), waterfowl (including ducks, geese, and seabirds), marine mammals (harbor seal), salmon, other finfish, marine invertebrates, plants, and firewood. The abundance and distribution of these resources on the Tongass is described in the 1997 Land Management Plan Revision Final EIS, as well as in other sections of this EIS.

Access

Road building, a byproduct of timber harvesting and, to a much lesser extent, mining, is an important agent of change in Southeast Alaska. These road networks provide greater access to areas previously unconnected and can affect subsistence both positively and negatively by providing access, dispersing hunting and fishing pressure, and creating the potential for increased competition. On Prince of Wales

Island, for example, areas that have become road-connected are now more easily reached through the ferry system, thus providing greater access from Ketchikan, one of the largest cities in the region. While road systems tend to bring more people into an area, they also give subsistence hunters access to previously remote regions and provide a greater opportunity for subsistence harvest.

Southeast Alaska is comprised of isolated islands unconnected by road systems; however, with the transportation means available (floatplanes, ferry systems, automobiles, boats), Southeast Alaska residents are very mobile in their subsistence resource use activities. Wrangell, the fifth largest community in Southeast Alaska, has documented their subsistence gathering from the southern tip of Prince of Wales Island to Yakutat, covering most of the islands in between (Kruse and Muth 1990).

Competition

The Tongass National Forest, with nearly 17 million acres of largely undeveloped land, includes extensive subsistence resources. These resources are not, however, distributed or used evenly across the Forest. Where the resources are confined to island groups or river systems and access is costly or nonexistent, use of the resources is low. Where the resource is abundant, and a community is present but access by other communities is costly, the resource tends to be used primarily by the community that resides in the area. Where resources are abundant and access is available to local and other communities of Southeast Alaska, competition for resources may exist.

Increased competition may result when less expensive access to the area or within the area is provided. Such is the case when road systems are established to local communities. When areas historically not used for subsistence purposes are made available because of easier, more cost-effective access, the new area then tends to be used. When communities with road access to abundant resources are connected to the ferry systems or to commercial air services, competition for the resources may be generated from outside communities with lower abundance of the same resource.

Examples of the effect of ease of access are readily available in Southeast Alaska. Chichagof Island, Prince of Wales Island, and the Yakutat Forelands at one time were isolated portions of the Tongass with limited use from communities in the vicinity. Today, road construction, primarily a result of timber harvest activities, has created relatively large areas that are easily accessed from local communities. Access provided by the ferry systems and small commuter planes to Chichagof and Prince of Wales Islands allows relatively easy access from off-island communities. Access to the Yakutat Forelands has been made easier because of commercial jet service and ferry service to the community of Yakutat.

The Southeast Alaska Federal Subsistence Regional Advisory Council noted an increased use of subsistence resources in the 1990s, and recommended decreases in harvest of deer, moose, and other wildlife species for non-rural residents. Competition for these resources typically increases with growth in the regional population and changes in access, such as the addition of new ferry services.

Subsistence Users

Under ANILCA only rural Alaska residents qualify for subsistence hunting and fishing on federal lands. Alaska residents living in urban areas can harvest under sport, personal use, or commercial regulations, but not under subsistence regulations. Following the Alaska Supreme Court's 1989 ruling in McDowell v. State of Alaska, all Alaska residents qualify as subsistence users on state lands with federal lands continuing to be managed under ANILCA.

In 2005, Southeast Alaska had an estimated population of 70,800, with the majority (about 91 percent) living in 32 established communities (Alaska Department of Labor [DOL] 2006). About 63 percent of the area's population lived in the city and borough of Juneau or Ketchikan Gateway Borough, the only two communities considered as urban areas for subsistence purposes. An additional 24 percent of the area's population resided in the communities of Sitka, Petersburg, Wrangell, Haines, and Craig. The remaining 13 percent of the population lived in communities ranging in size from Meyers Chuck with 15 people to Metlakatla with 1,342 people (Alaska DOL 2006).

In addition to permanent communities, there are a small number of logging camps across the Tongass National Forest that, in the past, were large enough and existed long enough to have had an effect on local uses of fish and wildlife. Currently, the remaining camps have few residents and do not have much effect on competition for resources.

A relatively small number of Southeast Alaska residents live at remote isolated locations. These include people living at homesites throughout Southeast Alaska, at summer fishing sites along the outer coast, tree thinners camped near areas where they have Forest Service contracts, trappers, and people living on floathouses and fishing boats. This diverse group is typically transient, generally has very low cash income, and is closely tied to non-commercial harvest of fish, game, and other renewable natural resources.

As in other parts of Alaska, Southeast Alaska's population grew with the expansion of government services following the oil boom. A number of new communities evolved around State land selections or timber harvesting activities in the 1980s and 1990s. Edna Bay, Coffman Cove, North Whale Pass, Thorne Bay, and other small Prince of Wales Island communities are examples. The population in Southeast Alaska increased in the 1990s, but has decreased since 2000, with approximately 2,300 fewer people living in the region in 2005 than in 2000 (Alaska DOL 2006).

Alaska Natives made up 17 percent of the region's population in 2000 and comprised about 23 percent of the total population of Southeast Alaska's 30 rural communities in 2000 (Figure 3.17-1). These rural communities include places that are predominately Native, such as Angoon, Hydaburg, and Metlakatla, other logging and fishing communities that may be predominately non-Native, and places with more mixed ethnicity. The Bureau of Indian Affairs identifies 17 localized Indian tribes in the region, including the Metlakatla of the Annette Island Reserve. At the time of contact, tribes occupied seasonal camps and temporary villages throughout traditional territories. In the late 1800s, the individual tribes of the region coalesced at what had been their winter villages. The area's extant tribes live within their earlier territories and use a similar set of subsistence resources and in this way maintain long standing ties to place. For Native people, this tie to place and the harvest and use of traditional foods are key elements in fostering Native cultural identity (Alaska Native Heritage Center 2000).

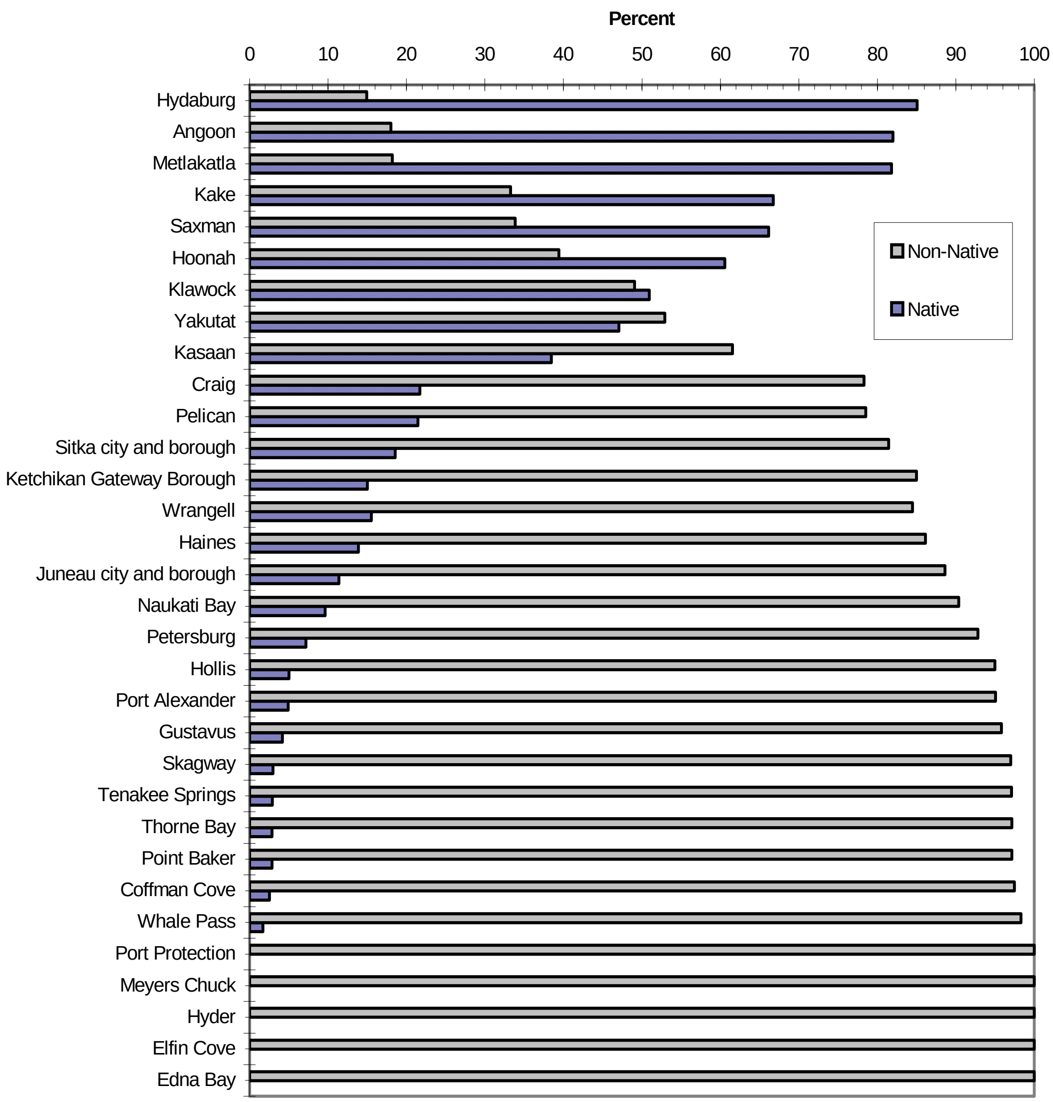
Economy

Subsistence use of fish and wildlife continues to be an important component of the economies of Southeast Alaska communities. In Native communities, harvest and use of wild resources supported the subsistence-based economy that predated the introduction of cash income. In the modern era, beginning in the late-1700s, the economies of Native communities have undergone a progressive transformation, incorporating cash income into the subsistence-based system. Southeast Alaska communities that were settled primarily by non-Native immigrants have also depended on a mix of subsistence use of wild resources and cash income.

Cash income in most Southeast Alaska rural communities is limited and intermittent, and frequently supports the purchase of fuel and equipment that are part of subsistence harvest technology. Subsistence harvests have been found to fill essential food needs in most rural communities in the region. These harvests are also customarily shared among community residents and between members of different communities. Some subsistence products are traded and bartered within the region. Subsistence harvests are not geared toward market sale or commercial profit. A mixed subsistence-market economy in which subsistence harvests and cash income are complementary characterizes the economies of most of the region's rural communities (Wolfe 2004).

Subsistence research conducted in Southeast Alaska over the past two decades has included detailed community studies, use area mapping, household surveys, and studies of specific subsistence harvests. During the 1980s, the Forest Service supported research that examined the impacts of timber harvests in the Tongass National Forest on subsistence resources in the area. The Tongass Resource Use Cooperative Survey (TRUCS) was completed in 1988 and followed by the Tongass Subsistence Studies. Data from TRUCS are summarized in the 1997 Tongass Land Management Plan Revision Final EIS.

Figure 3.17-1
Native/Non-Native Components of Southeast Communities, 2000



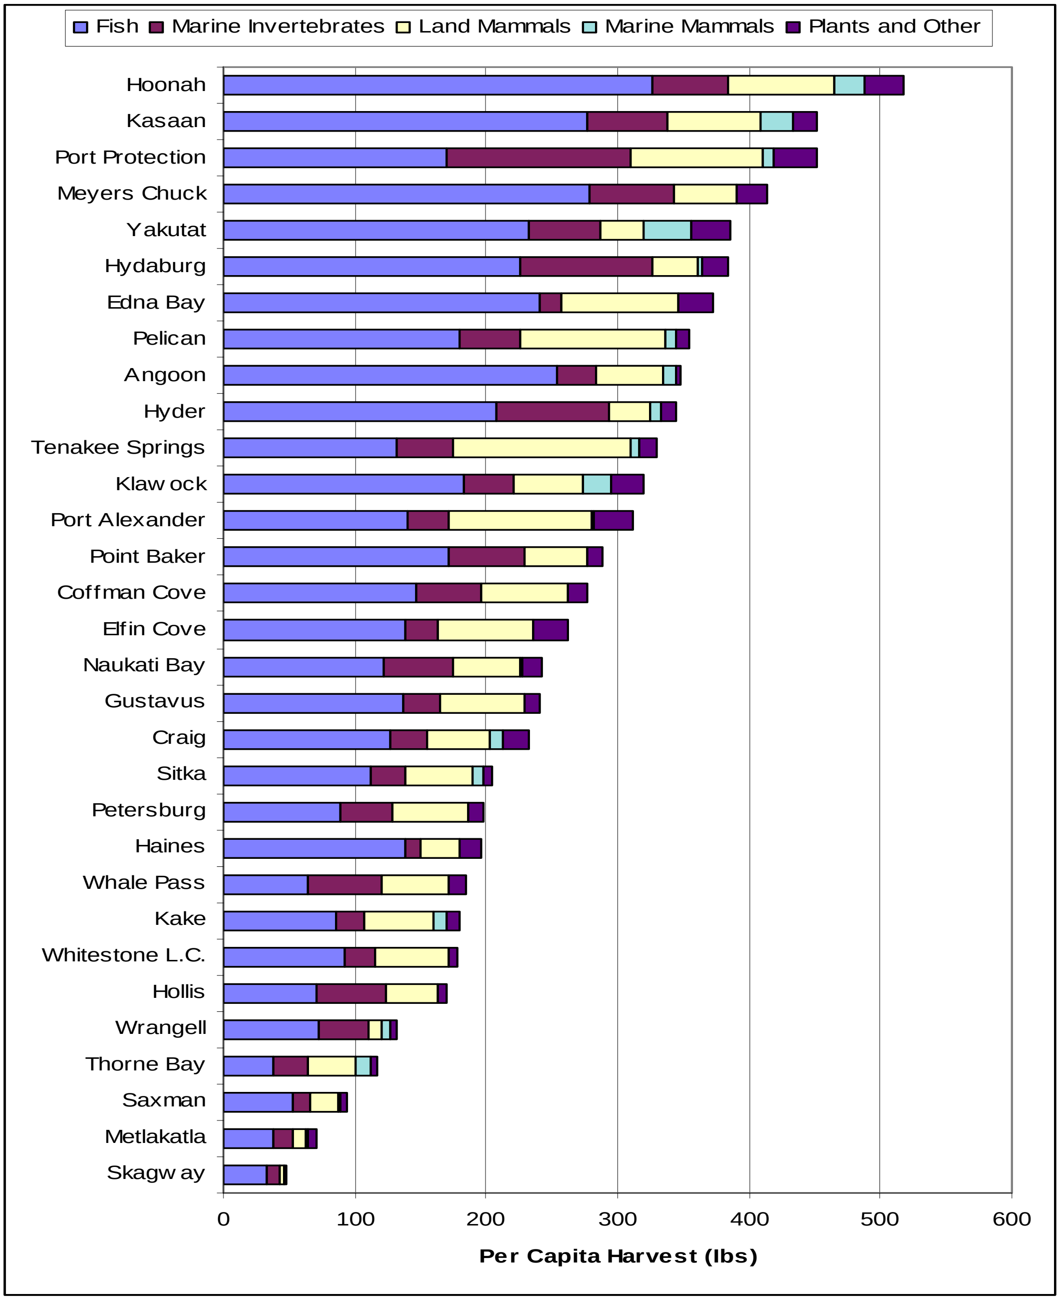
Source: U.S. Census Bureau 2001.

From 1987 to 2001, interviews were conducted with 1,064 households in 24 Southeast Alaska communities as part of the Forest Plan subsistence administrative studies. This fieldwork was conducted cooperatively with the Forest Service, Alaska Department of Fish and Game (ADF&G), and the area's tribes and communities all participating. Summary data from this and past community harvest assessments were compiled from the ADF&G Subsistence Community Profile Database (www.state.ak.us) and harvest levels are presented by community and species in Figure 3.17-2. The data presented in Figure 3.17-2 are the most recent available in the ADF&G database. The year these data were collected does, however, vary by community and the data summarized in Figure 3.17-2 should be considered a general overview of harvest patterns rather than an exact representation of current harvest activities.

The preliminary findings of this research are summarized in a recent unpublished paper by Schroeder and Mazza (2005) who identify a number of key subsistence characteristics that are evident in these data and generally consistent with the following past findings:

- Wild foods account for a large share of the diet for residents of the studied communities, ranging from 48 pounds per capita for Skagway in 1986 to over 500 pounds per capita for Hoonah in 1996 (see Figure 3.17-2). The average American diet includes about 225 pounds of meat, fish, and poultry on a per capita basis. In most of the study communities, wild foods came close to, or exceeded, this national average. Although residents of subsistence communities purchase food, most could meet their entire protein need from wild sources.
- Marine resources, including fish, mammals, and plants, comprise the majority of subsistence harvests in all communities when measured by food weight. Marine resources account for more than half of total per capita harvest in all Southeast Alaska communities, ranging from 55 percent in Tenakee Springs to 89 percent in Wrangell (Figure 3.17-2). As a result, management activities that restrict access for subsistence harvest of land mammals have had a relatively small effect on overall subsistence harvest by weight.
- Recent subsistence harvest levels in the main Native communities and the larger non-Native communities appear very similar to harvest levels estimated in the late 1980s or before. Harvest levels identified in the recent assessments conducted in Angoon, Hoonah, Hydaburg, Kake, Petersburg, Wrangell, and Yakutat, for example, are very similar to those identified in earlier studies. In a few communities, such as Coffman Cove, Kasaan, Klawock, and Port Protection, there are large differences in harvest levels over time. However, these differences seem to be more influenced by special events or small community sizes than by patterned changes in subsistence harvests.
- Subsistence harvest levels vary considerably from community to community. Recent research and other data suggest that intercommunity variability may not be fully explained by ethnicity, income, community size, or access to resources. Other factors, such as community demographic composition, cultural traditions and orientations, and community history, may have a larger influence on harvest levels than more easily analyzed standard socioeconomic variables.
- Subsistence harvesters use a wide variety of species, but use tends to be concentrated on a relatively small number of species. In Yakutat, for example, individual subsistence harvesters use as many as 65 of the 150 different species that are harvested in the community, but 84 percent of overall community harvest (in food weight) involves just 10 species. That said, the contribution of a particular species to the total subsistence harvest generally appears to vary from year to year, although the overall total harvest in food weight may remain nearly constant.

Figure 3.17-2
Per Capita Subsistence Harvest by Community and Resource Type



Note:
The year these data were collected varies by community, as follows:
1987: Elfin Cove, Gustavus, Hyder, Metlakatla, Meyers Chuck, Pelican, Petersburg, Port Alexander, Saxman, Skagway, Tenakee Springs, and Wrangell
1996: Angoon, Haines, Hoonah, Kake, Point Baker, Port Protection, Sitka, and Whitestone Logging Camp
1997: Craig, Hydaburg, and Klawock
1998: Coffman Cove, Edna Bay, Hollis, Kasaan, Naukati Bay, Thorne Bay, and Whale Pass
2000: Yakutat
Source: ADF&G 2006

- A small number of high harvesting households account for a disproportionate share of the total community harvest and tend to harvest more fish and wildlife than their family members can consume. The surplus is distributed to other subsistence users through a kinship network and through barter and trade. These networks are also used to distribute specialty subsistence products such as herring roe and hooligan oil, which are produced in large quantities in only a few communities. In Yakutat, for example, just 25 percent of subsistence households account for about 75 percent of total community subsistence harvest (in terms of food weight), with the lowest harvesting 50 percent of households taking just 8 percent of the total community harvest.

Subsistence Use Areas

Historically, subsistence use occurred where access to the resources cost less in energy than the resources gathered. Many of the gathering activities occurred in easily accessible areas. These activities occurred close to settlements where they could be accessed by foot or boat. Over time, as new technology developed, ease of access meant a movement outward into new resource use areas. The motorboat and development of road systems associated with timber harvest activities in Southeast Alaska have had perhaps the greatest influence on subsistence gathering activity. Today, all communities use motorized boats and many are tied to nearby lands by road systems. As new roads are developed, access is improved to a number of areas and subsistence use has moved to these areas.

The distribution of subsistence harvest activity is described in further detail in the 1997 Tongass Land Management Plan Revision Final EIS, with traditional household deer hunting areas mapped in Appendix H. These areas were identified based on the 1987 TRUCS (Kruse and Muth 1990). The traditional household deer hunting areas mapped in Appendix H show that the road systems are extensively used. This is particularly true on Prince of Wales Island. These maps also show that subsistence use is concentrated in close proximity to individual communities and along the beaches.

Each of the communities in Southeast Alaska has a distinct home range with concentrated use occurring within this range. A wide range of use typically occurs on a less concentrated scale outside the normal home range. More than half (54 percent) of all households surveyed in rural Southeast Alaska in 1987 traveled a minimum of 11 miles by boat to reach the one reliable deer hunting area that they chose to describe in TRUCS (Kruse and Muth 1990). An additional 18 percent of all households also used boats to reach their reliable deer hunting area, but traveled shorter distances (10 miles or less). Only 15 percent of all households used cars or trucks to travel to the most reliable areas. Thirteen percent used some other form of transportation, such as airplanes, walking, all-terrain vehicles, and the Alaska Marine Highway System (Kruse and Muth 1990).

While the majority of use occurs within about a 15-mile radius of rural communities, nearly all of the forested lands of the Tongass are used to some degree for subsistence deer hunting (USDA Forest Service 1997a). Appendix H in the 1997 Tongass Land Management Plan Revision Final EIS also displays, by community, the individual Wildlife Analysis Areas where approximately 75 percent of the average annual deer harvest occurred.

Kruse and Muth (1990) found that nearly one-half of the households harvesting deer mentioned the existence of clearcuts of various ages occurring in presently reliable areas (44 percent), most-often-used areas (48 percent), and areas no longer used (55 percent). They also reported that old-growth forests were mentioned as most reliable by 90 percent of households harvesting deer, were most-often-used areas by 91 percent of households, and were areas no longer used by 90 percent of those households harvesting deer.

Many of the fish and wildlife resource values of Southeast Alaska watersheds, based on the Value Comparison Unit (VCU) classification of the Tongass, are summarized in the 1998 Tongass Fish and Wildlife Resource Assessment (ADF&G 1998). This report shows the relative value of areas for black bear, brown bear, deer, sport fishing, salmon production, and subsistence use. This resource assessment also included a ranking of the VCUs that have the highest community use values.

Environmental Consequences

The analysis of the likely effects of the EIS alternatives on subsistence resources and uses is in two parts. Effects on subsistence resources and uses important to each rural community are discussed individually by community in the *Subregional Overview and Communities* section. Here, the Forest-wide evaluation is presented, based on general considerations in the three categories of effects previously identified: abundance and distribution, access, and competition. This general analysis relies on the community discussions and also on the Forest-wide effects analyses from the related resource sections (primarily *Fish* and *Wildlife*) where abundance and distribution are of concern.

Section 810 of ANILCA requires the Forest Service, in determining whether to withdraw, reserve, lease, or otherwise permit the use, occupancy, or disposition of NFS lands in Alaska, to evaluate the potential effects on subsistence uses and needs, followed by specific notice and determination procedures should there be a significant possibility of a significant restriction of subsistence uses. The Alaska Land Use Council's definition of "significantly restrict subsistence use" is one guideline used in the evaluation:

> "A proposed action shall be considered to significantly restrict subsistence uses, if after any modification warranted by consideration of alternatives, conditions, or stipulations, it can be expected to result in a substantial reduction in the opportunity to continue subsistence uses of renewable resources."

It should be noted that the term "significant" as used in this context does not have the same definition as used in the implementing regulations for NEPA. See 40 CFR Section 1508.27 for definitions of "significant" in a NEPA context.

Considerations of abundance and distribution, access, and competition (by non-rural residents) are mentioned.

The U.S. District Court Decision of Record in *Kunaknana v. Watt* provided additional clarification. In part it states:

> "restrictions for subsistence uses would be significant if there were large reductions in abundance or major redistribution of these resources, substantial interference with harvestable access to active subsistence-use sites, or major increases in non-rural resident hunting."

Direct and Indirect Effects

Abundance and Distribution

Based on the 1987 survey information compiled as part of TRUCS, 61 percent of subsistence resources (by weight) are fish or marine invertebrates, 21 percent are deer, 4 percent are other land mammals, and another 3 percent are marine mammals. More recent community data compiled by ADF&G (2006) indicate that fish and marine invertebrates still comprise the majority of subsistence harvest per capita (in pounds), ranging from 53 percent in Tenakee Springs to 88 percent in Skagway (see Figure 3.17-2).

The subsistence analysis conducted for the 1997 Forest Plan Revision Final EIS found that the primary subsistence resource likely to be significantly affected by the alternatives was Sitka black-tailed deer. Some effects to fish habitat may also result from land management activities, but the magnitude of the effects could not be calculated. Risk to fish habitat is generally expected to increase with increased timber harvest, increased roading, and narrower riparian areas along streams. A panel evaluation of alternatives was conducted for the 1997 Final EIS. Alternative 11, which essentially represents the adopted Forest Plan (Alternative 5 [No Action] in this EIS), was judged to have relatively low risk relative to the other alternatives.

As a result of their association with old-growth forest habitat, which is the main terrestrial habitat type affected by the alternatives, deer are considered the “indicator” for potential subsistence resource consequences concerning the abundance and distribution of the resources. The community-based subsistence analysis (see the *Subregional Overview and Communities* section) focuses largely on deer, which is, in most cases, by far the largest terrestrial component of subsistence food resources.

In the subsistence analysis in the 1991 Forest Plan Revision Supplemental Draft EIS (SDEIS), it was determined that at that time all of the Forest Plan alternatives, if implemented, could result in a significant restriction on the abundance and/or distribution of subsistence uses of Sitka black-tailed deer, brown bear, and marten sometime during the next 50 years. This conclusion was based on an analysis of the current status of huntable wildlife resources, and identified portions of the Tongass where such restrictions may already be occurring (i.e., were the result of existing conditions) (USDA Forest Service 1991, pp. 3-762 and 3-763). The unpublished 1992 Draft Final EIS reached the same conclusion for deer and brown bear. Such restrictions were most likely for communities with subsistence use areas in the northern portion of the Tongass (Chichagof and Baranof Islands, primarily). The Revised SDEIS came to the same conclusion in its analysis for deer.

In the 1997 Forest Plan Revision Final EIS, hunting demand and huntable populations of wildlife were only re-examined for Sitka black-tailed deer. Using a revised habitat capability model, the new deer analysis reached similar conclusions to that of the Revised SDEIS, based on specific areas where recent deer harvests are high relative to deer habitat capability. (This analysis was summarized at the end of the affected environment portion of the *Wildlife* section of the 1997 Forest Plan Revision Final EIS; see also Iverson 1996.) This analysis identified seven areas (near Juneau, Hoonah, Sitka, and Craig/Klawock) where current deer harvests exceeded 20 percent of the estimated habitat capability. This analysis also found another 23 areas exceeding 10 percent of capability (four on Admiralty, five on Chichagof, four on Baranof, eight on Prince of Wales, and two near Ketchikan). Areas exceeding 20 percent are those where deer harvest may be restricted, either directly through restrictions in seasons and bag limits, or indirectly through reduced hunter efficiency and increased difficulty in obtaining deer relative to historical rates. Hunters in areas between 10 to 20 percent may experience reduced hunter efficiency and moderate difficulty in obtaining deer. This analysis may underestimate negative effects when deer populations are below carrying capacity. Adverse effects to deer hunters may be further amplified with either reductions in deer habitat capability or increases in deer demand/harvest or both.

The 1997 deer analysis was much in line with the earlier (1991, 1992, and 1996) analyses, which also used the 10 and 20 percent harvest cutoffs and the same land units. It indicated that deer habitat capabilities in several portions of the Tongass may not be adequate to sustain the current levels of deer harvests, and that implementation of any Forest Plan alternative could, therefore, be accompanied by a significant possibility of a significant restriction on the abundance and/or distribution of subsistence uses of deer. (Sport hunting restrictions would, however, occur first, followed by selective subsistence reductions, based on ANILCA Section 804.) This possibility, at least in the short term, is largely due to the continuation of reduced habitat capabilities resulting from past habitat alterations, which is why it applied to all alternatives.

Under the alternatives analyzed in this EIS, the possibility of a significant restriction, resulting from a change in abundance or distribution, would be the same as or less than the possibility under Alternative 11 of the 1997 Forest Plan Revision Final EIS for five of the seven alternatives. This risk would, however, likely be higher under Alternatives 4 and 7 because these alternatives anticipate a higher level of timber harvest than the current Forest Plan (Alternative 5, No Action). It should be noted that actual timber harvest has been much lower under the current Forest Plan than the levels projected under Alternative 11.

In the short term, the risk of a significant restriction would be about the same under any of the alternatives because the effects of past harvest would override the effects of new harvest during the next 10 years. In the long term, those alternatives that limit the areas available for future timber harvesting the most would result in the largest reduction in risk.

Alternatives 5 and 6 would result in a similar possibility of a significant restriction relative to Alternative 11 of the 1997 Final EIS because they would not produce a substantial change in old-growth harvest rates relative to the that Forest Plan. Development LUD acreage under Alternative 5 is about 3 percent less than under Alternative 11 of the 1997 Final EIS and Alternative 6 would have about 7 percent fewer acres in development LUDs. These reductions are due to land adjustments that have occurred since 1997 and, in the case of Alternative 6, increases in the acreage of land in old-growth reserves and other non-development LUDs. Alternative 6 would have 4 percent fewer acres in development LUDs than Alternative 5, which is the 1997 Forest Plan, as amended. Alternatives 1, 2, and 3 would reduce the possibility of a significant restriction because of a 67, 46, and 18 percent reduction, respectively, in development LUD acreages compared with Alternative 5. Alternatives 7 and 4 would each result in an increase in the possibility of a significant restriction due to respective increases in development LUD acreages of 40 percent and 31 percent relative to Alternative 5.

Access

Subsistence users typically hunt and fish in traditional areas surrounding their communities. Many of the communities in Southeast Alaska are not located on the Alaska road system and tend to be compact, centralized places surrounded by undeveloped land with limited infrastructure. Most subsistence food production is supported by a central or core use area surrounding a community. Traditional household deer hunting areas are identified for the 32 communities in Southeast Alaska in Appendix H to the 1997 Forest Plan EIS. Access to and use of surrounding areas for subsistence activities may be guided by local customary rules, as well as federal and state regulation and economic considerations, with traditional use areas for different communities often overlapping at their margins. Customary rules guiding subsistence harvest may be related to local histories and social customs of clans and communities (Wolfe 2004).

Forest plans are programmatic, meaning that they establish direction and allowable activities for broad land areas, rather than schedule specific activities in specific locations. This makes it difficult to evaluate the effects of the alternatives on particular groups of subsistence users or resources. The following discussion addresses potential impacts at the programmatic or forest scale and assesses relative potential impacts in terms of overall proposed road construction and timber management activities.

Viewed at this scale, none of the alternatives would directly limit the use of public lands for the purposes of subsistence gathering activities. Historical access (by foot, boat, and floatplane) would remain available under all the alternatives for present and foreseeable future activities.

Data on documented deer harvest by transportation type are available at the Game Management Unit (GMU) level (Table 3.17-1). Data from the 2003 Deer Harvest Survey are presented by transportation type and GMU in Table 3.17-1. GMU 4, the ABC Islands (Admiralty, Baranof, and Chicagof Islands), accounted for 69 percent of deer harvested in Southeast Alaska in 2003 (7,621 deer), with GMU 2, Prince of Wales Island, accounting for 16 percent (1,783 deer). Hunters accessing hunting areas by boat accounted for 63 percent of total deer harvest in 2003. Hunters accessing the area by highway vehicle accounted for 23 percent of total deer harvest. The relative share of harvest by transportation type varies by GMU, with boat access, for example, accounting for 76 percent of harvest in GMU 4, but just 20 percent in GMU 2. Highway vehicle was the most frequently used method of access in GMU 2, Prince of Wales Island, accounting for 73 percent of deer harvest in 2003 (Table 3.17-1). This relatively high share reflects the more densely roaded nature of Prince of Wales Island and may be considered generally indicative of the effects of timber harvest and associated road building.

Table 3.17-1
Deer Harvest by Game Management Unit and Transportation Type, 2003

GMU Number[1/]	Area	Deer Harvested	Percent of Deer Harvested by Transportation Type[2/] Airplane	Boat	3- or 4-Wheeler	Highway Vehicle	Foot	Un-known
1A	Ketchikan	211	0	64	11	18	6	0
1B	Petersburg	82	0	39	44	0	17	0
1C	Juneau	467	0	33	0	48	16	2
2	Prince of Wales Island	1,783	2	20	1	73	3	2
3	Central Islands	901	1	52	11	31	1	2
4	ABC Islands[3/]	7,621	11	76	2	9	1	1
	Total	**11,065**	**883**	**6,938**	**329**	**2,529**	**240**	**139**
	Percent of Total	100	8	63	3	23	2	1

Notes:
1 Game Management Units (GMUs) are a geographic unit of measurement established and used by ADF&G.
2 These data were compiled as part of the 2003 Deer Hunter Survey and were collected in response to a question requesting the survey respondent to identify the Transportation Used to Get to the Hunt Area.
3 The ABC Islands are Admiralty, Baranof, and Chichagof Islands.
Source: ADF&G 2004.

New road construction is likely to result in the development of new use patterns around some communities, but these changes are not likely to lead to a significant possibility of a significant restriction of subsistence access to the resources. New use patterns may, however, favor some subsistence groups and disadvantage others. Subsistence access may be via a number of different transportation types and often involves more than one form of transportation. Subsistence users may, for example, access an area via boat followed by road (and on-foot) or via boat and on-foot, with types of access varying by location and user. Some hunters may access specific areas using more than one form of transportation, but others may favor one form of transportation over another, say highway vehicle over foot.

While there would be some new road access under all alternatives in the long run, nearly all new roads constructed under the alternatives would be closed following harvest. These roads would, therefore, not be available for use by highway vehicles or high-clearance vehicles. They may, however, be available for access by other methods and would, as a result, have the potential to affect existing subsistence patterns.

Based on the miles of new road construction projected under each alternative and viewed at a programmatic level, Alternative 1 would have the lowest impact on existing subsistence access patterns with only about 20 percent of the maximum road miles projected under Alternative 5 (No Action) (774 miles versus 3,874 miles). Also, new road construction under Alternative 1 would be limited to areas outside existing Inventoried Roadless Areas (IRAs) and would, therefore, tend to increase road density in already roaded areas rather than provide new access to presently undeveloped areas.

Alternatives 2 and 3 would also have relatively low impacts on existing subsistence access patterns with 1,751 and 887 fewer projected new road miles than under Alternative 5, respectively. These alternatives would also limit the construction of new roads in IRAs and, therefore, limit potential changes in access, but to a lesser extent than under Alternative 1. Alternative 6 (Proposed Action) would have a similar effect to Alternative 5, while Alternatives 4 and 7 would involve 1,136 and 1,913 more new road miles than Alternative 5 (No Action), respectively, and have the potential to provide new access to presently undeveloped areas.

Some subsistence users have a preference for unroaded areas. Viewed at a programmatic level, Alternative 1 would have the lowest impact on subsistence users who prefer unroaded areas because timber management would be primarily limited to areas outside the existing IRAs on the Tongass. Alternatives 2 and 3 would have the next lowest potential impacts, in that order, with timber management under Alternative 2 limited to areas outside the existing IRAs except in locations where existing roads could be logically extended. Alternative 3 would keep the 23 areas proposed for wilderness in HR 987 and the 18 Areas of Special Interest in the 1999 Record of Decision in a natural condition. Alternatives 5 and 6 would be more likely to involve timber harvest in IRAs; this likelihood would be increased further under Alternatives 4 and 7. Alternatives 4 and 7 have an increased emphasis on timber production with respective annual Allowable Sale Quantities (ASQs) of 313 million board feet (MMBF) and 421 MMBF in the first decade, compared to 267 MMBF under Alternative 5 (No Action) and 49 MMBF under Alternative 1.

Another potential access impact relates to the effects of clearcut harvesting on the landscape. Subsistence hunters have varying opinions on the effects of clearcut harvest on hunting success. Some hunters say that timber harvest clearcuts are productive for some years after harvest, while others prefer not to use clearcuts. Hunters interviewed on Prince of Wales Island, for example, reported that the best hunting in clearcut areas begins approximately 2 years after an area is logged, with hunt quality typically starting to decline 9 years after the area was cut (Brinkman 2006). Concern has been expressed by hunters that clearcuts in the process of regrowth become impassable to hunters after a period of time (Galginaitus 2004).

In addition to long-term access effects, timber management activities may also have short-term, temporary displacement effects for subsistence users because it is standard practice to close logging roads to outside traffic when logging is taking place. Subsistence users who use existing roads for access would be preempted from using those roads for the duration of logging activity in the affected area. These types of effects would, however, be short term and temporary, and would not be likely to lead to a significant possibility of a significant restriction of subsistence access to the resources. In addition, as previously noted, most or all new roads would be closed following harvest.

Competition

Just over half of the population in Southeast Alaska in 2005 resided in Juneau or Ketchikan (55 percent) and is, therefore, considered non-rural from a subsistence perspective. Residents in the remaining 30 communities and surrounding areas are considered rural. Competition for the more abundant wildlife and fisheries resources near rural communities results from a combination of factors, such as fish and game regulations, mobility, the natural distribution of game species across the Tongass, decreases in resource populations as a result of habitat reductions, decreases in resource populations as a result of over-harvest, and access provided to rural communities in the form of roads, ferries, and commercial air carriers.

For analyzing competition, the following assumptions are made:

- New road construction adjacent to communities with ferry access will result in increased competition from outside communities.
- New road construction adjacent to existing road systems where interties between communities exist will result in increased competition from surrounding communities associated with the interconnected roads.
- Habitat reductions will result in increased competition if regulations allow sport use to remain constant, with the same number of users seeking fewer huntable resources.
- The demand for resources will remain constant or increase slightly as the habitat capability remains the same or declines over time.

Given these assumptions, the 1997 Forest Plan Revision Final EIS concluded that implementation of Alternative 11 (the Selected Alternative) would result in a significant possibility of a significant restriction of subsistence use by increasing competition for some subsistence resources by non-rural, as well as rural residents. This was judged most likely to occur on Chichagof, Baranof, and/or Prince of Wales Islands, where competition for deer and some other land mammals is currently heavy, and habitat capability has been reduced as a result of timber harvest.

The possibility of a significant restriction, resulting from a change in competition, would be the same as or less than the possibility under Alternative 11 (the Selected Alternative) of the 1997 Forest Plan Revision Final EIS for Alternatives 5 and 6. There would be a relative reduction in risk under Alternatives 1, 2, and 3, and an increase in risk under Alternative 4 and especially under Alternative 7 (see the *Transportation and Utilities* section of this chapter).

Cumulative effects are discussed in four categories.

Cumulative Effects

1. **Effects Resulting from Timber Harvesting of Private Lands**. Native corporation lands adjacent to the Tongass National Forest support extensive timber harvest operations. Over the last two decades, old-growth forest wildlife habitat capability on Native corporation lands (especially that for deer) has declined, and this decline is expected to continue for at least the next two decades. This decline has occurred primarily on North Chichagof, Kupreanof, Admiralty (localized), and Prince of Wales Islands, as well as on mainland areas. Overall, approximately 351,000 acres, or 46 percent, of the original old growth has been harvested on non-National Forest System lands within the Forest boundary. The resulting lower habitat capabilities on these private lands are likely to increase hunting demands in adjacent National Forest areas, increasing competition and potentially leading to reduced hunter success, reduced or eliminated sport seasons, and in some places reduced or eliminated subsistence seasons.
2. **Effects from Past Activities**. Timber harvest has been more influential in changing the landscape than any other use of the resources of the Tongass National Forest. With timber harvest comes roading, log transfer facility development, and reductions in old-growth forest habitat. Intensive timber harvesting, which began in the 1950s, has resulted in approximately 455,000 acres of old growth harvest on National Forest System (NFS) lands.

3. **Effects of Present Activities**. Implementation of the current Forest Plan allowed an annual maximum timber harvest of approximately 267 MMBF (based on the ASQ), with an annual conversion of up to 8,900 acres of old-growth habitat to young growth (although a much lower volume and acreage has been harvested in recent years). This timber harvest involved the projected construction of up to 106 miles of classified road each year. In reality, less than 25 miles of new road has been built each year since the plan was implemented. One major mining operation, the Greens Creek Mine on Admiralty Island is currently operating. In addition, construction of the Kensington Mine project north of Juneau is partially underway and the mine may become operational in the near future.

4. **Effects of Reasonably Foreseeable Future Activities**. The conversion of old-growth forest habitat to young growth would occur at varying rates under all alternatives. The principal subsistence resource effect will be on Sitka black-tailed deer habitat, as previously discussed. If timber harvesting were to continue at maximum allowable rates (under Alternative 7) over the next 10 years, a maximum of 159,000 acres of old-growth habitat could change to young-growth and about 880 miles of road could be built on NFS lands. The comparison of alternatives at the end of Chapter 2, as well as the *Timber* and *Transportation and Utilities* sections, displays the estimated miles of road predicted under each alternative. With timber harvest activities would come new access, possibly new camps, and potential increased use of subsistence resources by rural and non-rural residents. The effects of timber harvest on deer habitat capability would be reduced somewhat, through more intensive management (e.g., thinning) of the existing and future closed-canopy, young-growth forests.

   Counting all lands in Southeast Alaska, an estimated 87 percent of the original old growth remains today. After 100+ years, it is estimated that the percentage of the original old growth remaining would range from 71 percent (Alternative 7) to 82 percent (Alternative 1), due to combined harvest on NFS and non-NFS lands, assuming maximum rates of harvest. Although the overall percentage reduction would not be excessively high overall, areas of concentrated harvest would have higher effects on subsistence. Areas of concentrated harvest are described in the *Biodiversity* section, which quantifies the estimated effects of cumulative future harvest on the amount of old growth by biogeographic province for all of Southeast Alaska (see Tables 3.9-20, 3.9-21, and 3.9-22).

Timber harvest of Native corporation lands is anticipated to continue at a relatively low but constant level over the next decade. New land selections could result in some previously unharvested areas being logged. Actual mineral development is difficult to predict, but effects to subsistence resources would be highly localized where it does occur.

ANILCA Determination

An ANILCA Section 810 evaluation and determination is not required for approval of a Forest Plan amendment, which is a programmatic level decision that is not a determination whether to “withdraw, reserve, lease, or otherwise permit the use, occupancy, or disposition” of National Forest land. This EIS is part of the Forest Plan Amendment process and, therefore, does not require an ANILCA Section 810 evaluation and determination. A Forest-wide evaluation and determination was, however, included for the 1997 Tongass Forest Plan Revision Final EIS to facilitate project-level planning and decisionmaking in compliance with ANILCA Section 810. The analysis and findings conducted for this EIS complement the 1997 effort.

Consistent with Section 810 of ANILCA, the alternatives considered in the Revised SDEIS (prepared prior to the 1997 Forest Plan EIS) were evaluated for potential effects on subsistence uses and needs, as described above. Based on that evaluation, it was determined that, in combination with other past, present, and reasonably foreseeable future actions, one or more of the Revised SDEIS alternatives (if implemented through project-level decisions and actions) may result in a significant restriction of subsistence uses of deer, and possibly other land mammals, due to potential effects on abundance and distribution, and on competition.

As a result of this finding, the Forest Service notified the appropriate state agencies, local communities, the Southeast Alaska Federal Subsistence Regional Advisory Council, and State Fish and Game Advisory Committees, and held hearings in affected communities throughout Southeast Alaska after publication and dissemination of the Revised SDEIS.

Using the information described earlier in this section and comments from the ANILCA 810 Subsistence Hearings, the alternatives considered in the 1997 Forest Plan Revision Final EIS were evaluated for potential effects on subsistence uses and needs, as described above. Based on this evaluation it was again determined that, in combination with other past, present, and reasonably foreseeable future actions, one or more of the 1997 Final EIS alternatives (if implemented through project-level decisions and actions) may result in a significant restriction of subsistence uses of deer, and possibly other land mammals, due to potential effects on abundance and distribution, and on competition.

ANILCA 810 Subsistence Hearings were also held in conjunction with the public meetings/hearings on the 2002 Draft SEIS. These meetings took place in 17 communities across Alaska; an internet hearing was also conducted. Subsistence hearings were also conducted for this EIS. They were held in 24 Alaska communities and on the internet as well (see Chapter 1).

Considering the input from these hearings and the analysis presented here, the same overall conclusion is reached regarding the alternatives evaluated in this EIS. The risk of a significant restriction would be the same or less than for the Selected Alternative from the 1997 Final EIS (current Forest Plan) under five of the alternatives, with the potential risk expected to higher under Alternatives 4 and 7.

Section 810 (a)(3) of ANILCA requires that when a significant restriction may result, three determinations must be made, including the following:

1. **Necessary and Consistent with Sound Management of Public Lands**. The alternatives proposed in this EIS have been examined to determine whether they are necessary and consistent with sound management of public lands. In this regard, the National Forest Management Act, the Alaska National Interest Lands Conservation Act, the Tongass Timber Reform Act, the Wilderness Act, the Alaska Regional Guide, the 1997 Forest Plan Revision Final EIS, as amended, the Alaska State Forest Resources and Practices Act, and the Alaska Coastal Zone Management Program have been considered.

   National Forest land management plans are required by the National Forest Management Act and must provide for the multiple-use and sustained yield of renewable forest resources in accordance with the Multiple-Use Sustained Yield Act of 1960. Multiple-use is defined as “the management of all the various renewable surface resources of the National Forest System so that they are utilized in the combination that will best meet the needs of the American people” (36 CFR 219.3). The alternatives presented herein represent different ways of managing Tongass National Forest resources in combinations that are intended to meet the needs of the American people. Each provides a different mix of resources uses and opportunities and has some potential to affect subsistence uses, although the effects would be the same or less than under the current Forest Plan for five of the alternatives, with the potential effects expected to higher under Alternatives 4 and 7. The potential restrictions associated with each alternative are necessary and consistent with the sound management of public lands.

2. **Amount of Public Land Necessary to Accomplish the Proposed Action**. The amount of land necessary to implement each alternative is, considering sound multiple-use management of public lands, the minimum necessary to accomplish the purpose of that alternative. The entire forested portion of the Tongass is used by at least one rural community for subsistence purposes for, at a minimum, deer hunting. It is not possible to avoid all of these areas in implementing resource use activities, such as timber harvesting and road construction, under any Forest Plan alternative, and attempting to reduce effects in some areas can mean increasing the use of others. The current and proposed Forest-wide standards and guidelines and LUD prescriptions provide for special management or limit activities in many of the areas most important for subsistence uses, such as beaches and estuaries, areas adjacent to roads, and areas with high fish and wildlife habitat values. Forest-wide standards and guidelines and LUD prescriptions are discussed in more detail below.

   The alternatives considered in this EIS, with the exception of Alternatives 4 and 7, would maintain the same levels of resource use and associated activities or would reduce them. There would be an increase in resource use under Alternatives 4 and 7. There would be a reduction in the beach and estuary buffers in the revised Forest Plan under Alternative 7. In addition, the Old-Growth Habitat LUD and its management prescription would be eliminated under Alternative 7.

3. **Reasonable Steps to Minimize Adverse Impacts to Subsistence Uses and Resources**. The Forest-wide standards and guidelines and LUD prescriptions of the current Forest Plan would continue to be implemented as part of Alternative 5 (No Action), where they apply. An updated and edited version of the current Forest Plan has been developed for Alternative 6 (Proposed Action), and for Alternatives 1, 2, and 3. Alternatives 4 and 7 also follow the Proposed Forest Plan, with some exceptions. One important exception in this context is the reduction in the beach and estuary buffers that would occur under Alternative 7. Beaches and estuaries are often important subsistence areas and reducing the buffers in these areas would reduce the level of protection and could have long-term impacts on subsistence users. In addition, the Old-Growth Habitat LUD and its management prescription would be eliminated under Alternative 7. Under Alternative 4, there would be Old-Growth Reserves would be limited to four high risk-biogeographic provinces. In other areas, 30 percent of old-growth would be reserved in each VCU.

   Subsistence use is addressed specifically in a Forest-wide standard and guideline, and subsistence resources are covered by the Forest-wide standards and guidelines for wildlife, fish, riparian areas, and biological diversity, among others. Fish and wildlife habitat productivity would be maintained at the highest level possible under all alternatives, consistent with the overall multiple-use goals of the current Forest Plan, with improved protection under the Proposed Forest Plan. Alternatives 1, 2, 3, and 6 would harvest less productive old-growth than Alternative 5 (No Action) and maintain a larger proportion of original old-growth on the Tongass. Alternatives 4 and 7 would harvest more productive old-growth than Alternative 5. There would be less deer habitat maintained in old-growth reserves under Alternative 4 than under Alternatives 1, 2, 3, 5, and 6. Alternative 7 would not include old-growth reserves and would have the largest potential long-term effects on the availability of deer for subsistence purposes. The potential effects of the alternatives on wildlife productivity are discussed in more detail in the *Wildlife* section of this EIS.

A final determination was made in the Record of Decision for the 1997 Tongass Forest Plan Revision Final EIS, which was consistent with the analysis above. A summary of the evaluation, findings, and determination for the alternative selected following this EIS process will be presented in the Record of Decision for this EIS.

Heritage Resources and Sacred Sites

Affected Environment

Heritage Resources

Heritage resources located within the Tongass National Forest include a diverse range of ancient and historic sites and artifacts that span approximately 10,000 years of human occupation and resource use. Ancient remains include campsites, village sites, graves, resource areas, rock art, portages, and rockshelters. Historic sites include houses, cabins, mines, trails, portages, canneries, boatworks, shipwrecks, and military installations. Many of these heritage remains provide the only record of former human occupation, work areas, and lifestyles.

The Tongass has implemented a Forest-wide heritage database (INFRA) to provide a more definitive tracking system for heritage surveys and sites. Based on this database, as of the end of Fiscal Year 2005, approximately 295,567 acres of National Forest System (NFS) lands have been inventoried for heritage resources and 2,096 heritage resource sites have been identified. As of the end of Fiscal Year 2005, 22 heritage resource sites or properties are listed in the National Register of Historic Places (National Register), while 878 sites or properties have been determined eligible for listing either through concurrence with the Alaska State Historic Preservation Office (SHPO) or by a decision of the keeper of the National Register. The Forest has added 421 newly discovered sites to the Alaska Heritage Resource Survey (a state-wide listing of heritage resources) in the last 4 years. Only a small portion of the Tongass National Forest has been surveyed; therefore, additional heritage sites are expected to be located within the Forest in the future. Information gathered from these inventory efforts provides information about heritage resource distribution and sensitivity to damage. Specific locations associated with Alaska Native traditional and religious use (sacred sites) are identified on an ongoing basis, with site-specific data kept confidential.

Certain types of heritage resources, such as sites, artifacts, and other observable results of human activity, have a greater probability of being located in specific areas, which create patterns of human use across the landscape through time. The environmental characteristics that invited human use and habitation in ancient times are often the same factors that invite use today. These high sensitivity areas, which are not evenly distributed across the landscape, are often below 100 feet in elevation and/or are areas of animal, plant, or mineral resource abundance. In addition, because of elevation and sea level changes after deglaciation, the locations of the earliest human activity areas may be farther inland and at higher elevations than more recent activity areas.

The Forest has established and maintains a heritage resource management program to identify, evaluate, protect, and enhance significant heritage resources on a Forest-wide and project-specific level in compliance with the National Historic Preservation Act (NHPA), as amended, as well as a number of other acts and implementing regulations. The Forest's ability to protect its heritage resources is affected by four factors: the location of the heritage property, the type of management activity conducted in that location, the environmental characteristics of the locality, and an active, effective heritage resource management program. Impacts to the resource may result from natural forces, public use, or project-related activities. Future management options will vary and are likely to be influenced by increased demands for scientific study, educational interpretation, public enjoyment, and preservation of traditional resources and sacred sites.

Inventory of these heritage resources is an ongoing process. Information gathered from inventories will provide insight into resource distribution and the sensitivity of sites to damage. Further scientific study will increase knowledge about early human migration, later exploration and development of the region, and human behavior in response to social and environmental change. Once data are collected, the Forest has the responsibility to curate artifacts and conserve records, photographs, and other data specific to heritage resource projects and sites under the 2005 Curation Agreement with the University of Alaska-Fairbanks Museum.

Sacred Sites

Sacred sites are places that have traditional spiritual values for Alaska Native people (Indian tribes or Indian religious practitioners) that are reverently dedicated to a person, object, event, or activity, and are secured against violation or infringement or interference.

In order to protect and preserve Indian religious practices, Executive Order 13007 and other laws and Executive Orders of the U.S. Government require the Forest Service, to the extent practicable, permitted by law, and not clearly inconsistent with essential agency functions to:

- Accommodate access to, and ceremonial use of, Indian sacred sites by Indian religious practitioners,
- Avoid adversely affecting the physical integrity of sacred sites, and
- Where appropriate, maintain the confidentiality of sacred sites.

Alaska Native groups or an appropriately authoritative representative of an Indian religion shall be responsible for identifying such sites to the Forest Service as the managing agency.

The Forest has developed Sacred Sites Protection Activities within the Heritage Resources Forest-wide standards and guidelines for the management of sacred sites as an integral part of its land management. The Forest also seeks to accommodate access to, and ceremonial use of, sacred sites by Indian religious practitioners, and to avoid adversely affecting the physical integrity of these sites. As early as possible, the Forest consults with tribes and their representatives on a government-to-government basis to provide notice of proposed actions or policies that may restrict access to or adversely affect the physical integrity of sacred sites.

The Forest is developing a knowledge base about sacred sites and tribal protocols, management recommendations, proposed guidelines, policies, or concerns about proposed actions that may affect sacred sites. Management includes undertaking government-to-government consultations with Alaska Native tribes and corporations and their representatives to monitor and protect sites from public access or other disturbance as needed. The Forest is also providing information and assistance on Alaska Native rights, trust responsibilities, preserving traditional beliefs and practices, and the laws and policies affecting management of historical, cultural, and traditional uses of NFS lands.

Heritage Resource and Sacred Sites Management Program

According to Forest-wide Heritage Resource Standards and Guidelines, the Forest maintains a heritage resource and sacred sites management program to identify, evaluate, protect, and enhance ancient heritage resources on a Forest-wide and project-specific level in compliance with federal legislation, their amendments, and implementing regulations. This includes coordinating management of heritage resources with the Alaska SHPO, Advisory Council on Historic Preservation (ACHP), and neighboring Alaska Native tribes and corporations. ACHP outlines this historic preservation review process in the Code of Federal Regulations (CFR) (36 CFR 800). Public involvement is a cornerstone of successful Section 106 review, and 1992 amendments to the NHPA place major emphasis on the role of Indian tribes. Subsequent revisions to ACHP's regulations, published December 12, 2000, incorporate specific provisions for federal agencies to involve Indian tribes throughout the Section 106 review process.

Heritage resource activities also include identifying and developing appropriate interpretive messages for heritage resource sites and activities; coordinating the management, access, and use of forest products to perpetuate Alaska Native culture and art forms; and developing a heritage resource management assessment that provides a framework for management decisions. The Forest annually reports upon all activities of the Heritage Program to the Alaska SHPO and the ACHP as stipulated in their Programmatic Agreement.

The Programmatic Agreement between the Forest Service – Alaska Region, ACHP, and Alaska SHPO regarding heritage resource management on National Forests was first signed in 1995, with amendments in 1999 and 2002. The purpose of this Agreement is to expedite compliance with the ACHP's regulations (36 CFR 800) implementing Section 106 of the NHPA. In lieu of the individual undertaking procedural requirements of the regulations, implementation of the Agreement enables the Forest Service to fufill some of its Section 110 responsibilities, such as the continuation of preservation and fostering appreciation of heritage resources through inventory, evaluation, protection, research, enhancement, education, restoration, stewardship, and interpretation programs. These programs are part of an effective heritage resource management program focused on heritage stewardship and public outreach. Section 110 of the NHPA and Executive Order 13287 directs federal agencies to use, to the maximum extent feasible, historic properties available to the agency. This direction must be taken into account as the agency considers the future of its administrative and recreation facilities in light of decreasing budgets. The Agreement recognizes the role of consultation with Alaska Native tribes and corporations on a government-to-government basis as well as the public.

The active participation of Alaska Native tribes and corporations and Alaska Native religious practitioners is critical to the success of sacred sites management. Heritage resource and tribal government relations specialists will collaborate to provide the Forest's line officers information necessary to make decisions related to sacred sites management. Tribal consultation will be conducted in a professional manner with tribal government officials, recognized Tribal Elders, and authoritative representatives. The consultation process will include regular review of proposed federal actions, development of a sacred sites knowledge base, protection of the physical integrity of sacred sites, and use alternative dispute resolution processes, if needed. The Forest will implement procedures to protect confidential information related to sacred sites.

If a tribal government chooses not to consult, the Forest will rely on the best available information to make decisions about sacred sites.

Environmental Consequences

Direct and Indirect Effects

Erosion and other environmental processes may deteriorate heritage sites through decomposition or mechanical destruction. Decomposition is most evident in objects or structures made of wood. Stabilization, regular maintenance, rehabilitation, and data recovery are means for preventing the loss of such objects or structures and the information they contain.

Public use may destroy heritage sites or sacred sites inadvertently or by intent. Inadvertent damage results from accessing sites resulting in compaction, or from other ground-disturbing activities. Intentional damage is looting and vandalism, including relic collecting, theft, and defacement, which result in the loss of information and destruction of the resource. Significant sites may be protected from destructive public uses by establishing public education programs, maintaining confidentiality about site-specific locations, monitoring, and directing public use away from the most vulnerable sites.

Areas managed for recreation provide opportunities for heritage resource protection and interpretation to promote public education and enjoyment. Active educational and interpretive programs can create a greater awareness of the importance of heritage resources and foster a sense of stewardship, while adding to the recreational experience. At the same time, protective measures must be implemented to control or eliminate intentional destruction of these areas by relic collecting, theft, and other forms of vandalism.

While multiple-use activities have benefited heritage resources by providing opportunities for inventory, evaluation, and interpretation in remote areas of the Forest, ground-disturbing activities have the most potential to adversely affect these resources and their environmental settings. The amount of impact an activity has is determined largely by the location and nature of the activity, the characteristics of the soils, and the degree of use.

Heritage resource and sacred sites management may increase the cost of project implementation. Some areas may need to be avoided entirely in order to protect the resource. This may increase the cost of site access and result in some loss of commercial products, such as timber. Protection of significant heritage resources or sacred sites often precludes ground-disturbing activities within a designated site boundary. When preservation of heritage resources in place is not desired or possible, mitigation of adverse effects to the resources may be necessary, and this in turn may delay projects and increase project costs. Normally, when the Section 106 process of the NHPA is completed early in the planning process, project delays and additional costs are minimal.

Under all of the alternatives, the preferred management of heritage resource sites eligible for, nominated to, or listed in the National Register is avoidance and protection. When this is not possible or feasible, it may be necessary to implement a mitigation program in order to achieve a finding of no adverse effect. Mitigation plans are developed in consultation with the Alaska SHPO, ACHP, Alaska Native tribes and corporations, and, possibly, other consulting parties. The potential for adverse effects, and therefore the need for mitigation, is diminished when the physical settings around significant heritage resources are maintained in a natural state.

Management of sacred sites includes early consultation with Indian religious practitioners and Indian tribes, development of site-specific protection strategies and enforcement mechanisms, and protection of the confidentiality of site-specific information. If sacred sites are identified during a project, the surrounding natural environment should be maintained and protected while consultation takes place and a protection plan is developed. If a sacred site is inadvertently disturbed or sacred or burial objects are exposed by natural causes, affiliated tribal governments will be notified within 24 hours.

LUDs allowing timber harvesting, mining, and road construction are most likely to affect heritage resources or sacred sites through alteration of environmental settings or damage to unknown sites as projects are implemented. However, existing standards and guidelines (e.g., those for riparian and beach and estuary buffer zones) result in the protection of most of the Forest's heritage resources. Recreation and special uses pose the greatest threat to heritage resources or sacred sites today, simply because people want to recreate and use the forest in the same places people have for thousands of years. In many instances, retention of a natural setting is crucial to imparting and protecting the values that qualify a heritage resource for National Register status or allow the undertaking of religious practices at sacred sites. Conversely, the opportunity for identifying new heritage resource sites is greater within these areas because such developments require more intensive heritage resource inventory efforts. ACHP, in their direction on sacred sites, point to the possibility that a sacred site (per Executive Order 13007) may not meet the eligibility criteria for the National Register. For example, a property with poor integrity might not be eligible to the National Register, but it may still be an important sacred site worthy of protection and other future management under EO 13007. An indirect effect common to all alternatives and prescriptions is that the discovery of new sites can lead to vandalism if locations become known to the public. An indirect effect specific to alternatives with proposed Wilderness designations is that such designation can indirectly lead to adverse effects to historic structures.

Potential effects to heritage resources and the differences in risk between the alternatives are difficult to measure. Table 3.18-1 identifies the maximum estimated acres of old growth and second growth that can be harvested and miles of road likely to be constructed under each alternative. These acreages and mileages provide relative indicators of potential adverse effects, with the alternatives having the most acreage and mileage are likely to produce the highest risk of effects. Under this scenario, Alternatives 4 and 7 have the highest risk because they include more area where development would be permitted. They would be followed by Alternatives 5, 6, 3, 2, and 1, in decreasing order of risk level. However, because project areas are inventoried for ancient and historic heritage resource sites and tribal consultation for sacred sites should occur prior to implementation and avoidance of impacts is the preferred option for resource protection, the levels of risk are considered relatively low for all alternatives. In addition, existing standards and guidelines should result in the protection of most heritage resources and sacred sites in those areas.

Table 3.18-1
Approximate Maximum Acres Likely to be Disturbed over 100+ Years

Alternative	Estimated Maximum Acres of Old Growth to be Harvested	Estimated Maximum Acres of Second Growth to be Harvested	Estimated Maximum Miles of New Road Construction
1	85,972	58,293	774
2	214,511	179,426	2,079
3	313,426	200,250	2,799
4	656,473	235,513	4,890
5	462,556	224,027	3,874
6	445,103	218,368	3,744
7	807,396	262,228	5,825

While it is true that increased project activity might accelerate the loss of heritage resources, primarily by improving public access and increasing the probability for looting and vandalism of heritage resource sites, there are potential positive effects as well. Over time, decay, neglect, and natural landscape changes threaten the preservation of significant heritage resources. By expanding the Forest's inventory of its heritage resources, development projects result in identification of many sites that might otherwise decay unnoticed. Once sites are known, the Forest is better able to protect and encourage collection of information from a greater number of them. By providing sufficient staff and funding to monitor known heritage resources and sacred sites, the Forest should be able to minimize looting and vandalism.

The Forest Plan and all of the alternatives include requirements for inventory, protection, preservation, and interpretation, and for consultation with Indian tribes or Indian religious practitioners and the Alaska SHPO as described in the Heritage Resource Standards and Guidelines. Effects are avoided or mitigated through a variety of measures at the project level. Avoidance measures may include protective enclosures, systematic monitoring of project activities, or mandatory restrictions on project design. Mitigation at heritage resources is undertaken when impacts cannot be avoided, and includes systematic recovery of the information through excavation, collection of materials, and detailed documentation as determined through consultation with the Alaska SHPO, ACHP, Indian tribes, and others. Protection of significant heritage resource sites and sacred sites from damage through public use includes establishing public education programs, maintaining confidentiality about specific locations, monitoring, and directing public use away from the vulnerable sites. The Forest is also required to consult with Alaska Native tribes and corporations when effects may involve sites of religious and/or cultural importance to them.

Cumulative Effects

The vast majority of Southeast Alaska (16.8 million acres) is occupied by the Tongass National Forest, so the disturbances described above for the Tongass are the major disturbances affecting heritage resources. However, Glacier Bay National Park, Haines State Forest, and other ownerships in the Haines/Skagway area occupy 3.6 million acres, while state, Native corporations, and other ownerships inside the Forest boundary occupy a combined 1.1 million acres. Therefore, activities on these lands contribute to Southeast Alaska cumulative effects. Disturbances in Glacier Bay and Haines/Skagway National Parks are generally very minor and contribute insignificantly to cumulative effects. However, extensive timber harvest, road construction, and urban development occur on these other ownerships. Because of the level of inventory required prior to development and the level of heritage resource protection required for discovered resources on Tongass National Forest lands, none of the alternatives should contribute significantly to the cumulative effects on heritage resources of Southeast Alaska.

Extensive landscape changes and ground disturbance have occurred and will continue to occur on many non-federal lands in Southeast Alaska. Federal laws requiring consideration for the protection of heritage resources do not apply to non-federal lands. Heritage resources are nonrenewable, and once disturbed they are permanently damaged or destroyed; their information and values are lost and cannot be recovered. Preservation of these resources and values on federal lands is critical so that future generations can continue to enjoy the heritage and knowledge about our past that we enjoy today.

Roadless Areas

Affected Environment

This section addresses inventoried roadless areas. The discussion is divided into three parts: the current roadless area inventory, the roadless area conservation rule, and the current situation on the Tongass.

Roadless Area Inventory

Roadless Area Terms

Roadless Area: For purposes of this EIS, this is a generic term that includes inventoried roadless areas and unroaded areas.

Inventoried Roadless Area: An undeveloped area typically exceeding 5,000 acres that meets the minimum criteria for wilderness consideration under the Wilderness Act.

Unroaded Area: An undeveloped area typically less than 5,000 acres but of a size and configuration sufficient to protect the inherent characteristics associated with its roadless condition.

The 1996 Tongass roadless inventory was updated following the March 2001 U.S. District Court of Alaska ruling (*Sierra Club v. Lyons*), which ordered the Forest Service to prepare a Supplemental EIS (SEIS) to evaluate roadless areas and to consider wilderness recommendations. As part of that effort, the Analysis of the Management Situation relative to roadless areas and their relative contribution to the National Wilderness Preservation System was completed.

This process involved a comprehensive update of the inventory of existing roads (including all classified and unclassified roads), harvest units, and land ownership on the Tongass National Forest. Developed areas were subsequently identified by buffering existing roads and harvest units. All areas within 1,200 feet of an existing road and within 600 feet of an existing harvest unit were considered developed; however, in order to be more inclusive, isolated beach-logged and helicopter units were not identified as developed areas. Narrow stringers of land between developed areas were also included as developed. All National Forest System (NFS) lands outside of areas defined as developed were identified as roadless areas. These roadless areas were then divided into two groups: areas greater than 5,000 acres and areas less than 5,000 acres. Inventoried roadless areas were identified as all roadless areas greater than 5,000 acres, as well as all inventoried roadless areas identified in previous inventories, which included some areas less than 5,000 acres. In addition, all other areas less than 5,000 acres were examined to determine if they were eligible for wilderness consideration. These included small roadless areas adjacent to existing wilderness.

The final inventory identified in the Final SEIS included 109 inventoried roadless areas covering 9.6 million acres. These inventoried roadless areas and other unroaded areas on the Tongass are identified on the roadless inventory map produced as part of this assessment and currently available on the SEIS Web site at www.tongass-seis.net.

Detailed descriptions of each individual roadless area that include an overview and a description of the capability, availability, and need for each area to be designated as wilderness are included as Appendix C to the Final SEIS (USDA Forest Service 2003b) and are also available on the SEIS Web site. These descriptions reflect current conditions and Forest Service Manual and Handbook direction. They also include an updated rating for each roadless area called the Wilderness Attribute Rating System (WARS), as well as a description of how each individual roadless area could contribute to the National Wilderness Preservation System.

The roadless area inventory displays the extent of the roadless resource and provides data for use by managers, legislators, and others to formulate land management proposals. Roadless areas may retain their roadless character by being managed in a way that emphasizes relatively large undeveloped or natural areas, such as areas usually required for old-growth habitat, scenic backdrops, or primitive recreation. Roadless areas identified in the inventory that are outside of existing the Wilderness Land Use Designation (LUD) may be considered for wilderness recommendation, or managed for a wide range of other resource management activities.

On the Tongass, the goals for a number of LUDs include the maintenance of areas in a primarily roadless state. One of these is called LUD II; these areas are to be managed in a roadless state to retain their wildland character. LUD II is a permanent LUD that was used by Congress in the Tongass Timber Reform Act (TTRA). TTRA established 12 permanent LUD II areas totaling 730,463 acres (including 2,701 acres of non-NFS land) (Table 3.19-1).

Table 3.19-1
National Forest System Land, Non-National Forest System Land, and Productive Old Growth within Each of the Legislated LUD II Areas Designated by the Tongass Timber Reform Act (in acres)

Name of LUD II Area	Total	National Forest System	Non-National Forest System	Productive Old Growth
Yakutat	139,045	139,035	10	72,312
Berners Bay	45,233	45,233	0	15,390
Anan	38,313	38,313	0	16,426
Kadashan	34,441	34,281	160	20,609
Lisianski/Upper Hoonah	149,088	147,132	1,956	44,178
Mt. Calder-Holbrook	60,863	60,863	0	38,682
Nutkwa	21,723	21,723	0	13,102
Outside Islands	75,720	75,342	378	45,999
Trap Bay	6,595	6,595	0	4,297
Pt. Adolphus/Mud Bay	116,877	116,695	182	38,249
Naha	31,365	31,350	15	17,875
Salmon Bay	11,200	11,200	0	4,811
Total	**730,463**	**727,762**	**2,701**	**331,930**

Roadless Area Conservation Rule

In May 2001, the Forest Service issued the Roadless Area Conservation Rule (Roadless Rule). This rule established prohibitions on road construction, road reconstruction, and timber harvest in inventoried roadless areas on NFS lands. In May 2001, the U.S. District Court for the District of Idaho enjoined the Forest Service from implementing the Roadless Rule, a decision that was subsequently appealed. In December 2002, a three-justice panel of the Ninth Circuit Court of Appeals reversed the Idaho ruling. The case was returned to the Idaho District Court for evaluation of the merits, and the State of Idaho then requested review by the full Ninth Circuit. Several other states, including the State of Alaska, filed lawsuits similar to that filed by the State of Idaho.

The litigation with the State of Alaska was settled in June 2003 and resulted in the July publication of a proposal to temporarily exempt the Tongass National Forest from the prohibitions of the Roadless Rule. On December 30, 2003, the Department of Agriculture adopted a final rule that withdrew the Tongass National Forest from the Roadless Rule, and the management of inventoried roadless areas on the Tongass is currently governed by the 1997 Forest Plan.

In May 2005, in response to legal challenges and the ongoing controversy surrounding the Roadless Rule, the Forest Service issued the Special Areas; State Petitions for Inventoried Roadless Area Management Final Rule, and decision memo (State Petitions Rule), which amended the Roadless Rule and established a petitioning process that provides Governors an opportunity to seek establishment of or adjustment to management requirements for NFS inventoried roadless areas within their states. Governors had until November 2006 to submit petitions.

Three states—California, Oregon, and New Mexico—filed a lawsuit in August 2005 challenging the May 2005 amendment, with Washington State later joining the case. In addition, Earthjustice filed a similar lawsuit in October 2005 on behalf of 20 environmental groups. The U.S. District Court, Northern District of California ruling on this case in October 2006 overturned the State Petitions Rule and reinstated the Roadless Rule, including the Tongass Amendment. (Updated information on the Roadless Rule is regularly posted on the Forest Service's Roadless Area Conservation Web site [www.roadless.fs.fed.us]).

The inventoried roadless areas included in the 2001 Roadless Rule are identified in a set of maps, contained in the Forest Service Roadless Area Conservation, Final Environmental Impact Statement, Volume 2, dated November 2000. For the Tongass, these maps represent 9.3 million acres and correspond closely with the 1996 roadless area inventory that was done for the 1997 Forest Plan Revision. Table 3.19-2 compares the areas protected by the Roadless Rule with the areas included in inventoried roadless areas for the 2003 Final SEIS, which covers 9.6 million acres. The differences are due to additional road building between 1996 and 2003, refinements of boundaries in 2003, and projects that were expected to be built in 1996 that were never implemented. Approximately 9.1 million of the 9.6 million acres in the Final SEIS inventoried roadless areas are also included under the Roadless Rule.

Current Situation

The Tongass National Forest, the largest Forest in the NFS, is more than 90 percent roadless, including wilderness. Only small areas where communities are developing, or where road construction and timber harvest have occurred, are "developed" to any noticeable degree. At various times in the past, "boom and bust" development (associated with fox farming, salmon canneries, mining, and military activity) resulted in the temporary development and occupation of small areas, mostly near the shoreline, that have since been largely reclaimed by nature. Developed areas cover about 1.3 million acres, or about 8 percent, of the Tongass (based on the updated roadless mapping described above). Southeast Alaska residents (approximately 71,000) are, for the most part, surrounded by land that has many of the characteristics of wilderness. Routine travel and ordinary outdoor recreation activities typically require a higher degree of skill, risk-taking, and self-reliance than is usually required of adventurous backcountry visitors on other National Forests. This wildness and the lifestyles associated with it are highly prized by residents and visitors alike.

Summary information is presented for the 109 inventoried roadless areas evaluated in the 2003 Final SEIS in Table 3.19-3 (USDA Forest Service 2003b). This information includes the size of each area in 2003, the amount of each area that is in productive old growth (POG), and the amount of each area that is considered suitable for timber harvest. The table also lists the WARS score for each of the roadless areas as a general indication of the wilderness attributes of the area. There are currently 9,514,105 acres in Inventoried Roadless Areas (IRAs) on the Tongass. This represents about a 44,000-acre reduction since the 2003 analysis, which is due to land adjustments, refinements to boundaries, additional road construction and harvest activity, and mapping corrections. If the additional 5,749,083 acres of the Tongass in Wilderness and Wilderness National Monument are combined with the IRA acreage, the total of 15,263,188 acres represents 91 percent of the Tongass.

	Total Acres	**9,558,266**	**2,684,657**	**307,465**	

[1] The estimated suitable acreage is based on the 1997 Tongass Forest Plan and was adjusted by the Model Implementation Reduction Factor (MIRF) and a Scheduling factor (see the *Timber* section of this chapter).

[2] The Wilderness Attribute Rating System (WARS), which was developed as part of the Roadless Area Review and Evaluation (RARE) II process in 1977, has a potential range from a minimum of 4 to a maximum of 28. WARS considers four main attributes and several supplemental ones. The main attributes are natural integrity, apparent naturalness, opportunity for solitude, and opportunity for primitive recreation.

[3] When more than one number is given, the roadless area was rated once for the entire roadless area and separate rating(s) were done for identified portions of the area. The ratings for portions of the roadless area are in parentheses.

Several characteristics of roadless areas on the Tongass are rather unique relative to other areas in the NFS. The Tongass has very large undeveloped land areas that could potentially be managed as wilderness or in an unroaded condition. Several portions of the Forest constitute contiguous roadless areas exceeding 1 million acres, and thus represent large, unfragmented wildlife habitats and exceptional opportunities for solitude.

Many of the Tongass roadless areas represent wildlife habitats, ecosystems, and visual character, such as coastal islands facing the open Pacific, extensive beaches on inland saltwater, old-growth temperate rain forests, ice fields, and glaciers that exist nowhere else in the NFS. Many of these areas are remote and difficult to access for primitive recreation, and many contain other important resources, such as timber, minerals, and salmon-producing streams. Of the slightly over 1 million acres of forest land that is mapped as suitable for timber production, approximately 763,000 acres are POG forest. Approximately 307,000 acres, or 40 percent, is within roadless areas.

Environmental Consequences

Direct, Indirect, and Cumulative Effects

There are currently 9,514,103 acres in IRAs on the Tongass. The allocation of these acres by LUD is presented for each alternative in Table 3.19-4. The individual LUDs are grouped into one of four categories: Wilderness and National Monument, Natural Setting, Moderate Development, and Intensive Development. The percent of IRA acres allocated to each category is summarized for each alternative in Table 3.19-5.

In general, management prescriptions for LUDs that allow moderate to intensive development include timber harvest with associated road and log transfer facility construction. There are guidelines for the extent and visual impact of such activities. LUDs that emphasize maintaining the natural setting and undeveloped character of the area generally do not allow timber harvesting or the development of major recreation facilities, although roads linking transportation systems, particularly major state corridors, may occur.

Not all areas allocated to LUDs that allow development would actually be developed. Development would occur mainly in areas with suitable forest lands. Some of the road construction would occur in areas already roaded. Some of the road construction would fragment existing roadless areas, either creating new roadless areas (if more than 5,000 acres remains) or simply resulting in small blocks of undeveloped land surrounded by roads and harvest areas. In addition, not all of the effects of the alternatives would occur at once.

Effects of Alternatives

The roadless lands allocated to Natural Setting LUDs would essentially remain roadless for the life of the current/proposed Forest Plan and, therefore, there would be no effect on the roadless values in these areas unless a vital transportation linkage or major utility system was constructed. Site-specific environmental analysis would be undertaken if this type of development were proposed.

Roadless lands allocated to moderate and intensive development LUDs would likely change over time. The amount of acres allocated to development LUDs and acres of forest land suitable for harvest are presented in Table 3.19-6.

It should be noted that the discussion below for each alternative assumes that the current/proposed Forest Plan is in effect and does not assume any effects of the Roadless Rule that was originally promulgated in January 2001 and has since been the subject of a number of lawsuits. As noted in the Affected Environment section,

[1] Table lists only Non-wilderness National Monument in this LUD group because Wilderness and Wilderness National Monument are not identified as Inventoried Roadless Areas (IRAs), even though they are roadless. In addition to the 9,514,105 acres of IRAs, the Tongass has 5,749,083 acres of Wilderness and Wilderness National Monument , for a total of 15,,263,188 acres (representing 91% of the Tongass).

Table 3.19-5
Allocation of Inventoried Roadless Area Acreage by LUD and Alternative (percent)

	Alternative 1	2	3	4	5	6	7
Wilderness and National Monument[1]	2%	2%	2%	2%	2%	2%	2%
Mostly Natural Setting	98%	90%	81%	62%	73%	74%	60%
Moderate Development	0%	2%	5%	11%	8%	7%	13%
Intensive Development	0%	6%	13%	25%	18%	17%	26%
Total	**100%**	**100%**	**100%**	**100%**	**100%**	**100%**	**100%**

[1] Only Non-wilderness National Monument is included in this LUD group because Wilderness and Wilderness National Monument are not identified as Inventoried Roadless Areas (IRAs), even though they are roadless. The Tongass currently contains 15,263,188 acres (representing 91 percent of the Tongass) of roadless lands if IRAs are combined with Wilderness and Wilderness National Monument.

Table 3.19-6
Acres of Development LUDs and Forest Land Suitable for Harvest within Current Inventoried Roadless Areas[1] by Alternative

Alternative	Acres of Development LUDs (includes Experimental Forests)		Acres of Forest Land Suitable and Scheduled for Harvest[2]	
	Acres	Percent of IRA Acres	Acres	Percent of IRA Acres
1	27,018	<0.5%	0	0.0%
2	811,680	9%	88,773	0.9%
3	1,672,442	18%	185,647	2.0%
4	3,428,299	36%	497,596	5.2%
5	2,430,802	26%	315,674	3.3%
6	2,314,147	24%	306,592	3.2%
7	3,667,166	39%	583,094	6.1%

[1] Inventoried Roadless Areas (IRAs) do not include Wilderness and Wilderness National Monument, even though they are roadless. In addition to the 9,514,105 acres of IRAs, the Tongass has 5,749,083 acres of Wilderness and Wilderness National Monument, for a total of 15,263,188 acres (representing 91 of the Tongass).
[2] Incorporates a reduction of 33 to 51 percent from mapped suitable, based on old-growth falldown and scheduling factors.

the Roadless Rule including the Tongass Ammendment, was reinstated in October 2006 by the U.S. District Court, Northern District of California.

Alternative 1

This alternative would keep virtually all existing IRAs in a natural condition. Less than 0.5 percent of the IRAs would be allocated to development LUDs under this alternative, compared to 26 percent under Alternative 5 (No Action). Less than 0.1 percent of the IRAs (less than 200 acres) would potentially be harvested (Table 3.19-6).

Alternative 2

This alternative keeps most IRAs in a natural condition, with timber harvest featured on lands outside of these roadless areas except for some areas where roads could logically be extended. Approximately 9 percent of the IRAs would be allocated to development LUDs under this alternative, compared to 26 percent under Alternative 5 (No Action). Approximately 0.9 percent of the IRAs (89,000 acres) would potentially be harvested under this alternative (Table 3.19-6).

Alternative 3

This alternative would keep the 23 areas proposed for wilderness in House Resolution 987 and the 18 Areas of Special Interest in the 1999 ROD in a natural condition. Approximately 18 percent of the IRAs would be allocated to development LUDs under this alternative, compared to 26 percent under Alternative 5 (No Action). Approximately 2.0 percent of the existing IRAs would potentially be harvested under this alternative (Table 3.19-6).

Alternative 4

Alternative 4 would provide for a mix of National Forest uses, with a greater emphasis on timber production relative to Alternatives 1, 2, 3, 5, and 6. Timber management would occur in some IRAs not managed for timber production in the current Forest Plan. Approximately 36 percent of the IRAs would be allocated to development LUDs under this alternative, compared to 26 percent under Alternative 5 (No Action). Approximately 5.2 percent of the existing IRAs would potentially be harvested under Alternative 4 (Table 3.19-6).

Alternatives 5 and 6

Alternative 5 (No Action) is the current Forest Plan (1997 ROD, as amended) and provides for a moderately high level of timber production along with strong resource protection measures. Alternative 6 (Proposed Action) is similar to Alternative 5 (No Action), but includes an expansion of the old-growth reserves and other adjustments to the Plan based on information generated during the recent 5-Year Plan Review, minor clarifications, and updates.

Approximately 26 and 24 percent of existing IRAs would be allocated to development LUDs under Alternatives 5 and 6, respectively. Approximately 3.3 and 3.2 percent would potentially be harvested under Alternatives 5 and 6, respectively.

Alternative 7

Alternative 7 would emphasize timber production relative to the other alternatives. Timber would be managed on a larger land base than under Alternative 4. Approximately 39 percent of the IRAs would be allocated to development LUDs under this alternative and approximately 6.1 percent would potentially be harvested (Table 3.19-6).

Cumulative Effects

This section considers the incremental effects of the alternatives when added to other past, present, and reasonably foreseeable actions. The effects of past and present actions on roadless areas are included in the affected environment portion of this section, which discusses the existing IRAs on the Tongass. IRAs are identified based on past actions—specifically, timber harvest and road development, with all areas on the Forest within 1,200 feet of an existing road or within 600 feet of an existing harvest unit considered developed. Present actions include the impacts of current management policies on roadless areas.

Reasonably foreseeable actions on NFS lands include the projected levels of future timber harvest and road construction. The direct and indirect effects analysis assesses the impacts of these actions on roadless areas under each alternative in terms of the percent of the IRAs that would be allocated to development LUDs and considered suitable for harvest.

Other reasonably foreseeable actions include transportation and utility developments proposed by the State of Alaska. These proposals are summarized in the *Transportation and Utilities* section of this document and in the *Introduction* to Chapter 3. A total of 2,657 miles of roads are projected to be constructed on non-NFS lands throughout all of Southeast Alaska after full implementation of the plan (100+ years) under each of the alternatives (see Table 3.12-3). Most of the projected non-NFS roads are forest roads that would be developed for timber harvest, but the total miles also include road corridors that would connect different communities and connect additional areas in Southeast Alaska to the continental highway system. A number of these state-proposed corridors covered by Public Law 109-59, would, if approved under NEPA and funded, cross IRAs. The Lynn Canal Highway corridor, for example, crosses IRAs 301-Juneau-Skagway Icefield and 305-Juneau Urban, north of Juneau. The Sitka to Baranof Warm Springs road corridor crosses IRAs 331-Sitka Urban and 330-North Baranof. The Bradfield Canal road corridor crosses a number of IRAs, including 208-Bradfield and 207-Harding.

If one or more of these or the other state-proposed corridors that cross IRAs were developed, the overall effect would be a reduction in the existing IRAs. It is not possible at this time to predict exactly which roads would be developed. None of the alternatives is expected to affect this type of future road development, which would be expected to go or not go forward regardless of the selected alternative. The overall cumulative effect of these regional road corridors viewed in conjunction with the proposed Forest Plan alternatives would be a reduction in existing IRAs. This trend would be would be most pronounced under Alternative 7 and least pronounced under Alternative 1, which, with the exception of potential regional transportation corridors, would virtually all remaining IRAs in a natural condition.

New utility line projects, if they were to go forward, would have similar effects. Potential utility projects include power lines between Juneau and Skagway, Juneau and Hoonah, Hoonah and Tenakee Springs, Tenakee Springs and Angoon, Angoon and Sitka, Sitka and Kake, Kake and Petersburg, Thorne Bay and Ketchikan, and Klawock and Hydaburg. Also planned are powerlines between the proposed Lake Dorothy, Otter Creek, Thayer Lake, and Sunrise Lake Hydroelectric Projects and existing powerlines or communities. A powerline from the Tyee hydropower site along a potential Bradfield Canal/Craig River road corridor route to Canada is also a potential route that has been considered. None of the alternatives would affect these developments, which would be expected to go or not go forward regardless of the selected alternative. The overall cumulative effects if one or more of the utility projects that cross IRAs were developed would be a reduction in the existing IRAs; this would be most pronounced under Alternative 7 and least pronounced under Alternative 1.

The Tongass National Forest comprises about 78 percent of the land area of Southeast Alaska. Over 90 percent of the Tongass is currently roadless or wilderness. The other major land ownership in Southeast Alaska is Glacier Bay Park and Preserve (12.5 percent of Southeast Alaska), the vast majority of which is managed as wilderness by the National Park Service. In addition, the State of Alaska and the Bureau of Land Management manage another 6 percent of Southeast Alaska, a large portion of which is roadless. Combining all ownerships, approximately 90 percent of Southeast Alaska is currently roadless. In addition, it is estimated that at least 70 percent of all existing IRAs would remain roadless under any of the alternatives after 100+ years of Forest Plan implementation. As a result, it is estimated that at least 73 percent of Southeast Alaska would remain in wilderness or roadless after 100+ years (assuming all non-NFS lands become roaded, except for Glacier Bay and 50 percent of non-NFS lands in the Haines/Skagway area). Although these percentages remain high, it is likely that a higher proportion of lower elevation lands containing POG forest would become roaded over the long term.

Wilderness

Affected Environment

Introduction

This section provides a general overview of wilderness, describes existing wilderness in Alaska and on the Tongass National Forest, discusses the relative contribution of Tongass wilderness to the National Wilderness Preservation System, and addresses wilderness management direction in Alaska. The only other National Forest in Alaska, the Chugach National Forest, currently has no designated wilderness, but includes 2 million acres of wilderness study area.

Roadless areas within the Tongass National Forest were evaluated for recommendations as potential wilderness in the 2003 Forest Plan Supplemental EIS (SEIS) (USDA Forest Service 2003b). The 2003 SEIS evaluated eight alternatives that ranged from no new recommended wilderness to 9.6 million acres (all inventoried roadless areas) of new recommended wilderness. None of the alternatives evaluated in this EIS includes new Wilderness or LUD II recommendations.

Wilderness Overview

The Wilderness Act of 1964 defines wilderness “as an area where the earth and its community of life are untrammeled by man, where man himself is a visitor who does not remain.” The Act further elaborates on the definition to mean:

> an area of undeveloped federal land retaining its primeval character and influence, without permanent improvements or human habitation, which is protected and managed so as to preserve its natural conditions and which 1) generally appears to have been affected primarily by the forces of nature, with the imprint of man’s work substantially unnoticeable; 2) has outstanding opportunities for solitude or a primitive and unconfined type of recreation; 3) has at least five thousand acres of land or is of sufficient size as to make practicable its preservation and use in an unimpaired condition; and 4) may also contain ecological, geological, or other features of scientific, educational, scenic, or historical value.

Wilderness Character

The Wilderness Act does not define wilderness *character*, but according to Landres et al. (2005), wilderness character may be described as the “combination of biophysical, experiential, and symbolic ideals that distinguish wilderness from all other lands.” Landres et al. identify four qualities of wilderness that may be used to approximate wilderness character for the purposes of monitoring changes to wilderness character over time. These qualities, which were identified based on the Definition of Wilderness, Section 2(c) from the 1964 Wilderness Act, and are described below, are equally important and reinforce one another.

Untrammeled—The Wilderness Act states that wilderness is “an area where the earth and its community of life are untrammeled by man” and “generally appears to have been affected primarily by the forces of nature.” This quality refers to wilderness being essentially unhindered and free from modern human control or manipulation.

Natural—The Wilderness Act states that wilderness is “protected and managed so as to preserve its natural conditions.” This quality refers to the intended and unintended effects of modern people on ecological systems inside wilderness since the time of designation.

Undeveloped—The Wilderness Act states that wilderness is “an area of undeveloped federal land retaining its primeval character and influence, without permanent improvements or human habitation.” The undeveloped quality refers to the presence of structures, construction, habitations, and other evidence of modern human presence or occupation, including the development level of trails and campsites.

The undeveloped quality also refers to the absence of mechanical transport and motorized equipment. Wilderness was partly established “in order to assure that…growing mechanization, does not occupy and modify all areas within the United States…” (Wilderness Act, Section 2a).

Outstanding opportunities for solitude or a primitive and unconfined type of recreation—The Wilderness Act states that wilderness has “outstanding opportunities for solitude or a primitive and unconfined type of recreation.” This quality includes the values of inspiration and physical and mental challenge. Primitive recreation in wilderness has largely been interpreted as travel by nonmotorized and nonmechanical means. It also encompasses reliance on personal skills to travel and camp in an area. Unconfined encompasses attributes such as self-discovery, exploration, and freedom from societal and managerial controls.

The existing wilderness on the Tongass was established under the 1980 Alaska National Interest Lands Conservation Act (ANILCA) and the 1990 Tongass Timber Reform Act (TTRA), which subsequently amended ANILCA. In ANILCA, Congress reaffirmed and expanded upon the purposes of wilderness as stated in the 1964 Wilderness Act, specifically for wilderness established in Alaska. In recognition of unique situations and established uses in Alaska, ANILCA also provided a number of important specific exceptions to the prohibitions of the Wilderness Act. These included exceptions related to subsistence, access, and public use cabins among others. These exceptions are addressed in detail in the final part of this Affected Environment section and also apply to wilderness established under TTRA.

Wilderness Values

People value wilderness for a variety of reasons, but most reasons involve three central themes: the *experiential* value, the *scientific* and *ecological resource* value, and the *symbolic* and *spiritual* values (slightly modified from Hendee and Dawson 2002). The *experiential* value is the direct value of the wilderness experience. The experience is seen as valuable in its own right because of its primitive recreation, aesthetic, closeness to nature, education, freedom, solitude, simplicity, spiritual, and mystical dimensions. The value of wilderness as a *scientific* and *ecological resource* includes the importance of wilderness to science, including its importance in preservation of fauna and flora, particularly those species requiring large tracts of unmodified habitats. Finally, the *symbolic* and *spiritual* values of wilderness are represented by the high values some people place on the knowledge that wilderness exists, whether they use it or not. In a world characterized by rapid change and complexity, wilderness symbolizes comforting stability and simplicity to many.

Wilderness in Alaska and the Tongass

Congress has the sole authority for designating additions to the National Wilderness Preservation System. Congressionally designated wilderness on the Tongass National Forest comes from two pieces of legislation: ANILCA of 1980 and TTRA of 1990. Fourteen wildernesses totaling 5.5 million acres were established under ANILCA. Two of these areas, Admiralty Island and Misty Fiords, are also designated as National Monuments. Prior to ANILCA, there was no designated wilderness on the Tongass. TTRA subsequently amended ANILCA and designated five new wildernesses and one wilderness addition totaling 296,080 acres. As a result of these two pieces of legislation, there are currently 5.8 million acres of wilderness on the Tongass in 19 separate wildernesses (Table 3.20-1).

Wilderness recommendations were not considered in the 1997 Forest Plan Final EIS and Record of Decision (ROD) because additional wilderness had been created under TTRA. In March 2001, the U.S. District Court of Alaska ruled in response to a lawsuit filed by the Sierra Club (*Sierra Club v. Lyons*) and other environmental groups that the 1997 Final EIS should have considered making additional wilderness recommendations and ordered the Forest Service to prepare a Supplemental EIS (SEIS) to evaluate wilderness recommendations and update the Analysis of the Management Situation (AMS) relative to roadless areas and their relative contribution to the National Wilderness Preservation System. The Forest Service subsequently updated the AMS and determined the eligibility of each of the inventoried roadless areas for wilderness recommendation. Eight alternatives that identified roadless areas within the Tongass for recommendation as potential wilderness were evaluated in a Final SEIS to the 1997 Forest Plan Final EIS in 2003 (USDA Forest Service 2003b). The ROD for the Final SEIS concluded that it was not “the appropriate time for significantly changing land use designations on the Tongass National Forest” and did not recommend any additional wilderness on the Tongass at that time (USDA Forest Service 2003b).

The wilderness acreages summarized in Table 3.20-1 reflect the legal descriptions as reported to Congress. These acres are not exactly the same as those generated by the geographic information system (GIS) used in the analysis for the 1997 Tongass Forest Plan Revision Final EIS or for this Final EIS. The differences are due to different resolutions in mapping and the method of generating acres. The 1997 Final EIS used a point grid system to measure acreage using the GIS, based on the legal descriptions. This Final EIS measures the area based on the mapped GIS polygons. In addition, there were slight differences in mapping small islands or large rocks in saltwater. These differences in measurement and mapping result in a total wilderness acreage of 5,756,472, compared to the legal description total of 5,752,221. This represents a difference of less than 0.1 percent. The slightly higher total is used in this document for the purposes of analysis.

Table 3.20-1
Existing Wildernesses on the Tongass National Forest

Name	Total Acres	Non-National Forest Acres	National Forest Acres
Wildernesses Established December 2, 1980, by ANILCA			
Kootznoowoo Wilderness (Admiralty Island National Monument)	988,050[1]	32,129	955,858[1]
Coronation Island Wilderness	19,232	0	19,232
Endicott River Wilderness	98,729	0	98,729
Maurelle Islands Wilderness	4,937	0	4,937
Misty Fiords National Monument Wilderness	2,142,907	600	2,142,307
Petersburg Creek-Duncan Salt Chuck Wilderness	46,849	0	46,849
Russell Fiord Wilderness	348,701	0	348,701
South Baranof Wilderness	319,568	0	319,568
South Prince of Wales Wilderness	91,018	50	90,968
Stikine-LeConte Wilderness	449,951	1,025	448,926
Tebenkof Bay Wilderness	66,839	27	66,812
Tracy Arm-Fords Terror Wilderness	653,179	0	653,179
Warren Island Wilderness	11,181	0	11,181
West Chichagof-Yakobi Wilderness	265,529	1,038	264,491
Wildernesses Established November 28, 1990, by TTRA			
Chuck River Wilderness	74,990	692	74,298
Karta Wilderness	39,894	5	39,889
Kuiu Wilderness	60,581	0	60,581
Pleasant-Lemusurier-Inian Islands Wilderness	23,151	55	23,096
South Etolin Wilderness	83,371	752	82,619
Total Acreage	**5,788,657**	**36,436**	**5,752,221**

[1] Kootznoowoo Wilderness includes 18,486 acres, including 24 acres of Non-National Forest System lands in the Young Lake Addition established by TTRA, November 28, 1990.

Source: Total acreages are as reported to Congress with official boundary maps. These wildernesses include only the public lands above mean high tide.

Relative Contribution of Tongass Wilderness

General Perspective

The National Wilderness Preservation System includes almost 105 million acres. More than half of this acreage is in Alaska (Figure 3.20-1). In addition to having the largest land area in wilderness, Alaska also has the highest percentage of its land area in wilderness among the 50 states (Figure 3.20-2). The states with both the greatest land area and highest percent land area in wilderness are Alaska, California, Washington, Idaho, and Arizona (Landres and Meyer 2000).

In addition to having the greatest amount of land and the highest percentage of its land base in wilderness, Alaska also has the highest number of wilderness acres per resident, with almost 90 acres per resident. This ratio increases to slightly more than 120 acres per resident when only Southeast Alaska is considered. The next closest state is Wyoming with about 6 acres of wilderness per resident.

Existing wilderness on the Tongass, approximately 5.8 million acres, represents about 34 percent of the forest land base and 28 percent of the land in Southeast Alaska. Viewed on a national basis, existing wilderness on the Tongass represents 17 percent of all wilderness on National Forest System (NFS) lands and 5.5 percent of all lands in the National Wilderness Preservation System (USDA Forest Service 2000a).

Two of the largest wildernesses on the Tongass, Misty Fiords National Monument Wilderness (2.1 million acres) and Kootznoowoo (Admiralty Island) Wilderness (almost 1 million acres), contain vast, virtually intact ecosystems. Five other wildernesses are each more than 250,000 acres. The wildernesses of the Tongass are mostly in a pristine condition, with the imprint of humans generally not noticeable. They offer outstanding opportunities for solitude and primitive recreation.

In the remainder of this section, the Tongass National Forest is evaluated in terms of how well its landforms and ecosystems are represented in existing wilderness (and LUD II areas). Four ways of classifying the Tongass landforms and ecosystems are considered, ranging from very broad (e.g., ecoregions, with two categories covering the Tongass) to fairly detailed (e.g., ecological subsections, with 73 categories covering the Tongass).

Ecoregions

DeVelice and Martin (2001) provide a national summary of acreage in National Forest roadless areas versus designated wilderness, National Parks, and other areas primarily managed to maintain natural values (i.e., conservation reserves). In Alaska, all but 1 of 15 ecoregions (as defined by Ricketts et al. 1999) have greater than 12 percent of its area in reserves. No other region in the country surpasses Alaska in ecological representation in reserves.

Two ecoregions cover the Tongass National Forest: the Northern Pacific Coastal Forest and the Pacific Coastal Mountain Tundra and Ice Fields (Ricketts et al. 1999). These two ecoregions extend from eastern Kodiak Island to the southern end of the Alaska panhandle. Approximately 19 percent of the Northern Pacific Coastal Forest and 37 percent of the Pacific Coastal Mountain Tundra and Ice Fields ecoregions are in reserves (DeVelice and Martin 2001). The portions of both of these areas protected in wilderness are well above the 12 percent threshold considered by some authorities (e.g., World Commission on Environment and Development 1987) as the minimum area for representation (DeVelice and Martin 2001).

Figure 3.20-1. Acres of Wilderness by State

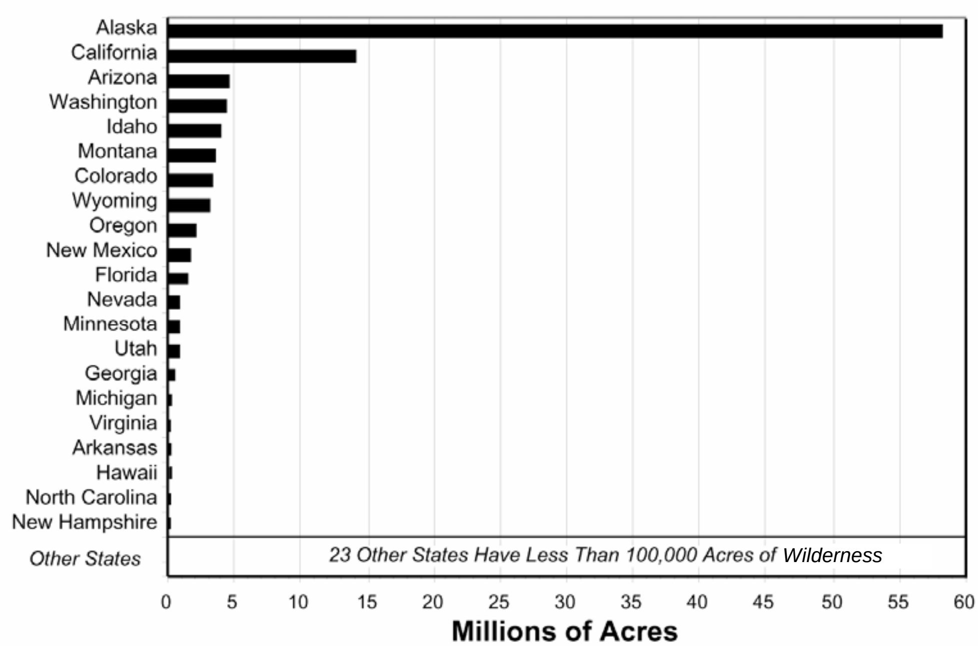

Figure 3.20-2. Percentage of Land Area in Wilderness by State

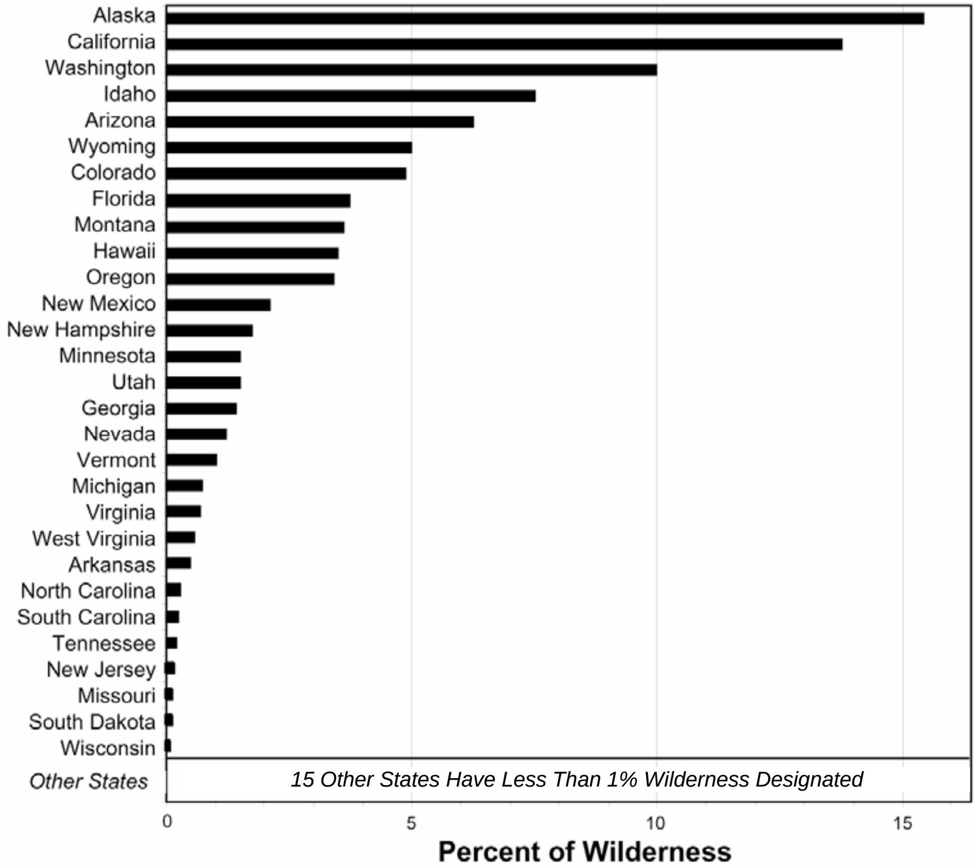

When the acreage of inventoried roadless areas is added to the acreage of conservation reserves in the two ecoregions, the percentage increases to 64 percent for the Northern Pacific Coastal Forest and 66 percent for the Pacific Coastal Mountain Tundra and Ice Fields ecoregions (DeVelice and Martin 2001). These values are in the 25 to 75 percent range that Noss and Cooperrider (1994) argue is required to achieve representation and are substantially higher than the 12 percent threshold.

When one considers only NFS lands, the percentage of NFS lands area in wilderness in these ecoregions is 25 percent for the Northern Pacific Coastal Forest and 21 percent for the Pacific Coastal Mountain Tundra and Ice Fields. If all inventoried roadless areas are counted along with wilderness, the total area of wilderness plus inventoried roadless areas on the Tongass in these ecoregions increases to 69 percent and 79 percent, respectively (DeVelice and Martin 2001).

Land Cover Classes

The various wildland ecosystems of Southeast Alaska are generally represented within the Tongass' wilderness. These areas include glaciers and ice fields, off-shore islands and seacoasts facing both the open Pacific Ocean and inland passages, major river systems, and 1.5 million acres of old-growth temperate rain forests. Viewed in terms of broad National Forest land cover classes, designated Wilderness on the Tongass exceeds 12 percent of the area in five land cover classes that are prevalent in Southeast Alaska. These five classes are: 1) Evergreen Forest (23 percent), 2) Tundra (15 percent), 3) Barren Land (37 percent), 4) Water (23 percent), and 5) Glaciers-Snow (15 percent). Designated

Wilderness does not exceed 12 percent of the area for Deciduous Forest (0 percent), Mixed Forest (0 percent), and Shrub-Brush (9 percent) (Martin et al. 2000). However, these latter three land cover types are not prevalent in Southeast Alaska.

Biogeographic Provinces

The extent to which identifiable landform types and ecosystems are represented in the wildernesses (and other natural setting LUDs) of the Tongass National Forest is addressed by reviewing the extent to which the biogeographic provinces of Southeast Alaska are represented. The Tongass can be subdivided into 21 biogeographic provinces characterized by similar species composition, similar patterns in distribution for many species, similar geologic barriers and historic events (such as glaciation), and similar climatic conditions. These provinces are discussed in the *Biodiversity* section of this chapter. Table 3.20-2 identifies the percentage of each biogeographic province that is included in existing wilderness. This table also identifies the percentage in LUD II areas because these are Congressionally designated areas managed for long-term protection to retain their wildland character. It also includes the percentage of each biogeographic province in other natural setting LUDs.

Table 3.20-2
Percent of Each Biogeographic Province in Wilderness, LUD II, or other Natural Setting LUD (within the Tongass National Forest boundary)

	Province	Percent in Wilderness or National Monument	Percent in LUD II	Percent in Other Natural Setting LUDs[1]	Total Percent in Wilderness or Natural Setting LUDs[1]
1	Yakutat Forelands	2%	39%	38%	79%
2	Yakutat Uplands	37%	0%	62%	100%
3	East Chichagof Island	6%	25%	16%	47%
4	West Chichagof Island	81%	6%	12%	99%
5	East Baranof Island	23%	0%	50%	73%
6	West Baranof Island	29%	0%	55%	84%
7	Admiralty Island	90%	0%	5%	96%
8	Lynn Canal	15%	6%	58%	78%
9	North Coast Range	23%	0%	48%	71%
10	Kupreanof/Mitkof Island	6%	0%	27%	32%
11	Kuiu Island	26%	1%	38%	64%
12	Central Coast Range	38%	0%	37%	75%
13	Etolin Island	16%	0%	25%	41%
14	North Central Prince of Wales	3%	5%	28%	35%
15	Revilla Island/Cleveland	18%	5%	35%	58%
16	South Outer Islands	16%	33%	23%	72%
17	Dall Island and Vicinity	0%	0%	51%	51%
18	South Prince of Wales	22%	5%	33%	61%
19	North Misty Fiords	82%	0%	14%	96%
20	South Misty Fiords	100%	0%	0%	100%
21	Ice Fields	33%	0%	62%	95%
	Total	**33%**	**4%**	**37%**	**74%**

[1] Note that totals may not add due to rounding.

Seventeen of the 21 biogeographic provinces on the Tongass have 20 percent or more of their lands within the National Forest boundary, in Wilderness, National Monument, or LUD II areas; 18 of the 21 have 15 percent or more. Three provinces—Dall Island and Vicinity, Kupreanof/Mitkof Island, and North Central Prince of Wales—have from 0 to 8 percent in Wilderness, National Monument, or LUD II areas. However, these areas have from 32 to 51 percent of their land areas within wilderness or natural setting LUDs. Overall, 17 of the 21 provinces have more than 50 percent of their land areas in either wilderness or natural setting LUDs. The remaining four have 32 to 47 percent.

Ecological Subsections

The extent to which identifiable landform types and ecosystems are represented in wilderness LUDs (and other natural setting LUDs) of the Tongass can also be evaluated by reviewing the extent to which the ecological subsections of Southeast Alaska are represented (Nowacki et al. 2001). These subsections are discussed in the Biodiversity section of this chapter. Table 3.20-3 identifies the percentage of each subsection that is covered by existing Wilderness (or National Monument), LUD II areas, and other natural setting LUDs.

Table 3.20-3
Percent of Each Ecological Subsection in Wilderness, LUD II, or Other Natural Setting LUD (within the Tongass National Forest boundary)

[1] Note that totals may not add due to rounding.

Forty-two of the 73 ecological subsections on the Tongass National Forest have 20 percent or more of their lands inside the National Forest boundary within Wilderness, National Monument, or LUD II areas; 47 of the 73 subsections have 15 percent or more. Twenty-six of the subsections are not represented in Wilderness, National Monument, or LUD II areas. All of these subsections are represented in natural setting LUDs. Sixteen of the 17 ecological subsections with no Wilderness, National Monument, or LUD II representation have more than 20 percent of their areas in natural setting LUDs. The Klawock Inlet Till Lowlands has only 7 percent in natural setting LUDs.

Wilderness Management in Alaska

Monitoring has been minimal in most of the wilderness, but some resource damage and user conflicts have been observed in localized concentrated use areas. Monitoring in some of the more remote areas, such as the South Prince of Wales and Coronation Island wildernesses, indicates very little use but some resource damage and occupancy trespass. The areas with the greatest use and most management activities tend to have the greatest need for additional management direction to help resolve user conflicts and preserve the wilderness resource.

Implementation of existing direction has varied greatly between the various wildernesses. Some areas, such as Kootznoowoo (Admiralty Island) and Misty Fiords Wildernesses, have had significant management programs and accomplishments, while others have had minimal management activities. Some of these activities, such as fisheries enhancement projects and the authorization of temporary facilities for the taking of fish and wildlife, have resulted in administrative appeals by user groups who view these activities as conflicting with their use or wilderness values.

Management under the Wilderness Act

The Wilderness Act of 1964 mandates that designated "wilderness areas … shall be administered for the use and enjoyment of the American people in such a manner as will leave them unimpaired for future use and enjoyment as wilderness, and so as to provide for the protection of these areas, the preservation of their wilderness character, and for the gathering and dissemination of information regarding their use and enjoyment as wilderness."

Subject to existing private rights, the Act prohibits permanent roads and, except as necessary for realizing the recreation and other wilderness purposes of the area, commercial enterprises. Temporary roads, the use of motor vehicles, motorized equipment, other mechanized equipment, motorboats, the landing of aircraft, and structures and installations are prohibited except as necessary to meet minimum requirements for the administration of the area as wilderness. The Act provides that the use of aircraft or motorboats, where these uses have already become established, may be permitted to continue subject to restrictions by the Secretary of Agriculture. Wildernesses were withdrawn from mineral entry as of December 31, 1983, and patenting of valid claims is limited to subsurface mineral rights.

Management under the Alaska National Interest Lands Conservation Act

In ANILCA, Congress reaffirmed and expanded upon the purposes of wilderness as stated in the Wilderness Act of 1964, specifically for wilderness established in Alaska. In recognition of unique situations and established uses in Alaska, ANILCA also provided a number of important specific exceptions to the requirements of the Wilderness Act. These apply equally to TTRA Wilderness.

Subsistence Policy

Section 811 mandates that the Secretary "shall ensure that rural residents engaged in subsistence uses shall have reasonable access to subsistence resources on public lands." This section further directs that, other laws (including the Wilderness Act) notwithstanding, the Secretary "shall permit on the public lands appropriate use for subsistence purposes of snowmobiles, motorboats, and other means of surface transportation traditionally employed for such purposes by local residents, subject to reasonable regulation."

Transportation and Utility Systems

Section 1105 provides that in any case in which there is no applicable law with respect to a transportation or utility system, the head of the federal agency concerned shall make recommendations to authorize the system within the Conservation Unit concerned (including Wilderness) if he determines that the system would be compatible with the purposes for which the unit was established, and there is no economically feasible and prudent alternative route for the system. ANILCA (Section 506) includes specific exceptions for Admiralty Island National Monument Wilderness regarding the right to develop hydroelectric resources and public access and use.

Special Access

Section 1110(a) requires that the Secretary "shall permit" on Conservation Units, which include Wilderness, "the use of snowmachines (during periods of adequate snow cover or frozen river conditions, in the case of Wild or Scenic rivers), motorboats, airplanes, and nonmotorized surface transportation methods for traditional activities (where such activities are permitted by this Act or other law) and travel to and from villages and homesites." Such use is subject to reasonable regulation, but shall not be prohibited unless after notice and hearing the Secretary finds that such use would be detrimental to the resource values of the area.

Inholding Access

Section 1110(b) assures adequate and feasible access to state and private land and to valid occupancies, including valid mining claims.

Navigation Aids and Facilities

Section 1310(a) provides that reasonable access to, and operation and maintenance of, existing air and water navigation aids, communication sites, facilities for national defense, and related facilities and existing facilities for weather, climate and fisheries research, and monitoring shall be permitted. "Nothing in the Wilderness Act shall be deemed to prohibit such access, operation and maintenance within wilderness areas designated by this Act." Section 1310(b) provides that the establishment, operation, and maintenance of new such facilities shall be permitted within wilderness after consultation with the Secretary and in accordance with mutually agreed upon terms and conditions to minimize the adverse effects within the unit.

Aquaculture

Section 1315(b) provides that the Secretary may permit fishery research, management, enhancement, and rehabilitation activities within National Forest System Wilderness, in a manner that adequately assures protection, preservation, enhancement, and rehabilitation of the wilderness resource. Subject to reasonable regulations, permanent improvements and facilities such as fishways, fish weirs, fish ladders, fish hatcheries, spawning channels, stream clearance, egg planting, and other accepted means of maintaining, enhancing, and rehabilitating fish stocks may be permitted.

Public Use Cabins

Section 1315(c) provides for the continued use, maintenance, and replacement of existing public use cabins within wilderness. Section 1315(d) authorizes the construction and maintenance of a limited number of new public use cabins and shelters, if necessary, for public health and safety, and also requires the Secretary to notify Congress of his intention to remove an existing or construct a new public use cabin or shelter.

Beach Log Salvage

Section 1315(f) allows the Secretary to permit or otherwise regulate the recovery and salvage of logs from the coastlines of National Forest Wilderness and National Monuments.

Temporary Hunting and Fishing Facilities

Section 1316(a) provides that the Secretary shall permit, subject to reasonable regulation to ensure compatibility, the continuation of existing uses and future establishment and use of temporary campsites, tent platforms, shelters, and other temporary facilities and equipment directly and necessarily related to the taking of fish and game. Facilities and equipment shall be constructed, used, and maintained in a manner consistent with the protection of the area where they are located. New facilities shall be constructed of materials that blend with and are compatible with the surrounding landscape. Section 1316(b) allows the Secretary to deny new facilities and equipment upon making a determination, after public notice, that the establishment and use of new facilities or equipment would constitute a significant expansion of existing facilities or uses that would be detrimental to the purposes for which the unit was established, including “wilderness character.”

Other Forest Plan Restrictions

In spite of its many exceptions to the Wilderness Act, ANILCA defines “wilderness” as having the same meaning as when it is used in the Wilderness Act (Sec. 102(13)). Further, Section 707 states that, except as expressly provided in ANILCA, Alaskan wilderness “shall be administered in accordance with applicable provisions of the Wilderness Act governing areas designated by that Act as Wilderness.” Some of the additional restrictions identified for Tongass wilderness by the current Forest Plan include the following:

- New roads and airstrips are not permitted, except to access state and private inholdings and valid mining claims, subject to stipulations for protection of natural and other values of the land.
- Helicopter use is generally not permitted, except on a case-by-case basis. In the 1997 Record of Decision for the Helicopter Landings in Wilderness Final EIS, the Regional Forester decided not to allow establishment of helicopter access areas within wilderness on the Tongass National Forest for use by individuals and helicopter companies transporting the general public.
- There is a party size limitation for outfitter/guide operations of no more than 12 persons for any one site or activity.
- No new permanent administrative facilities are allowed, except as consistent with ANILCA.

Environmental Consequences

None of the alternatives involves recommending new areas for Wilderness or LUD II designation. Roadless areas within the Tongass National Forest were evaluated for recommendations as potential wilderness in the 2003 Forest Plan SEIS (USDA Forest Service 2003b). The 2003 SEIS evaluated eight alternatives that range from no new recommended wilderness to 9.6 million acres (all inventoried roadless areas) of new recommended wilderness. This evaluation and the ROD for the 2003 SEIS are incorporated here by reference.

Direct and Indirect Effects

Existing wilderness on the Tongass, which encompasses approximately 5.8 million acres and represents about 34 percent of the forest land base and 28 percent of the land in Southeast Alaska, would remain unchanged under all of the alternatives. The existing 19 wildernesses on the Tongass are identified in Table 3.20-1. The acres of each biogeographic province and ecological subsection presently in Wilderness or LUD II areas on the Tongass would also remain unchanged (see Tables 3.20-2 and 3.20-3).

Alternatives 1 through 4, 6, and 7 would, however, differ from Alternative 5 (No Action) because under these alternatives wilderness on the Tongass would be managed under the updated and edited version of the current Forest Plan presented as Volume II to this EIS. The updated version of the Forest Plan includes substantial edits and clarifications to the Wilderness and Wilderness National Monument LUD prescriptions. These edits emphasize that wilderness should remain untrammeled and free from modern human control or manipulation, including actions taken to manage wilderness. The edits also modify the objectives of both LUD prescriptions to emphasize primitive Recreation Opportunity Spectrum (ROS) classes, rather than both primitive and semi-primitive ROS classes. Areas managed as semi-primitive within a wilderness are an exception and are not encouraged. In addition, new standards and guidelines that address forest health with respect to non-native, invasive species, sacred site protection activities, and karst management are included in the revised Wilderness and Wilderness National Monument LUD prescriptions. These edits and others are shown in the revised Forest Plan included in Volume II.

The updated Forest Plan also provides more specific standards and guidelines with respect to managing recreation activities to meet appropriate levels of social encounters. This includes limiting group sizes to no more than 12 persons for commercial and general public use of a wilderness, limiting the length of stay at one location to 14 days, and limiting commercial recreation use to two groups of 12 people from a single vessel (or other form of transportation), with the groups required to disperse out of sight and sound from each other. Implementation of these standards and guidelines is expected to help preserve outstanding opportunities for solitude and emphasize primitive recreation opportunities.

These edits and revisions are not intended to change the management of Wilderness or Wilderness National Monument areas. Rather, the intent is to ensure that the objectives of the LUD prescriptions laid out in the current Forest Plan are met. As a result, with the possible exception of the revised Recreation and Tourism Standards and Guidelines (discussed above), there is not expected to be a substantial difference between Alternative 5 (No Action) and the other alternatives in this respect.

Cumulative Effects

There would be no change in the number of acres with Wilderness or LUD II designations on the Tongass under any of the alternatives. While there are edits and clarifications to the Wilderness and Wilderness National Monument LUD prescriptions under six of the alternatives, these would not substantially change the management of these areas.

The Tongass National Forest comprises about 78 percent of the land area of Southeast Alaska. The other major land ownership is Glacier Bay Park and Preserve, the vast majority of which is managed as wilderness by the National Park Service. Combining the Glacier Bay Wilderness with the wildernesses on the Tongass, nearly 40 percent of Southeast Alaska is in wilderness under existing conditions. Thus, the proportion of lands in wilderness in Southeast Alaska is substantially higher than the statewide average for Alaska (15 percent). Further, the State of Alaska contains more wilderness, on both an acreage and percentage basis, than any of the other 49 states. In addition, as discussed in the *Roadless* section of this EIS, at least 60 percent of all existing inventoried roadless areas would remain roadless after 100+ years of Forest Plan implementation. As a result, it is estimated that at least 73 percent of Southeast Alaska would remain in wilderness or roadless after 100+ years (assuming all non-NFS lands become roaded, except for Glacier Bay and 50 percent of non-NFS lands in the Haines/Skagway area). Thus, the potential for cumulative effects associated with precluding options for future wilderness is considered low.

Other Special Land Use Designations

A number of specific areas on the Tongass National Forest that have not been designated as Wilderness or Land Use Designation (LUD) II areas are given special LUDs because they possess outstanding resources, research opportunities, or other factors of special interest. These areas include experimental forests, research natural areas, Special Interest Areas, and wild and scenic rivers. Each of these special areas is described, as are the effects of the alternatives on these areas, in this section.

Affected Environment

Experimental Forests

Experimental forests provide areas for conducting manipulative research that serves as a basis for forest management. Natural resources in experimental forests are used or altered under controlled scientific studies. The Tongass currently has two experimental forests, Maybeso and Young Bay, with a combined area of 17,260 acres. Their locations are indicated on the alternative maps.

Maybeso

Established in the early 1950s as a part of an intensive research program to document the effects of large-scale clearcutting on hydrology, fisheries, and timber productivity, the Maybeso Experimental Forest (10,600 acres) is located in a large steep-sided alluvial valley with a south to southeast-facing aspect near the central-eastern coast of Prince of Wales Island. By the early 1960s, most of the suitable forest land on the experimental area had been harvested. Permanent research plots were established and monitored to study hillslope erosion, movement of large woody debris in and through streams, forest regeneration, and silvicultural responses to precommercial thinning. Most of these plots are still monitored. The upper slopes of the Maybeso watershed are included in Roadless Area 510.

Because nearly all of the old-growth timber on the Maybeso Experimental Forest has been harvested, the timber in the area is primarily young growth. Consequently, there are limited opportunities to design new harvest-related experiments, except potential experiments concerning second-growth timber of up to 45 years in age. Only a limited variety of vegetation and timber types are now available within the area.

Young Bay

The Young Bay Experimental Forest (6,660 acres) is located just south of Juneau on northern Admiralty Island. Originally selected for long-term hydrologic and fisheries monitoring with a paired comparison between streams, this site was used extensively for fisheries and hydrology research in the 1960s and 1970s.

The Young Bay Experimental Forest has an extensive terrace, or bench, underlain by poorly drained marine silt (the Gastineau Formation) that extends across its lower slopes between sea level and an elevation of 100 feet. As a result of this formation, part of the experimental forest is open and relatively unproductive, which is atypical of areas normally managed for timber production in Southeast Alaska. Young Bay exhibits little forest vegetation-type diversity, making its use for studies not related to timber production difficult. High winds often limit access to the area during winter. There are no roads and, to date, no experimental vegetation treatments have occurred. The Young Bay Experimental Forest is located entirely within the Greens Creek Roadless Area 307.

The Tongass Timber Reform Act (TTRA) designated lands to the east of the Young Bay Experimental Forest as the "Young Lake Addition" to be managed as part of the Admiralty National Monument and Kootznoowoo Wilderness.

Young Bay has been considered for delisting as an experimental forest. This area has limited research opportunity, and limited applicability to other areas of the Forest. Manipulative research may not be compatible with the adjacent Monument/Wilderness addition.

Because of the TTRA legislation or other resource conflicts, Shaheen Creek, Trap Bay, Staney Creek and Chicken Creek watersheds, previously identified as possible experimental forests in the 1990 DEIS, are no longer appropriate for consideration and these areas were not included in the 1997 Forest Plan.

Research Natural Areas

Research Natural Areas (RNAs) are part of a national network of ecological areas designated for research and education and/or to maintain biological diversity of representative ecosystems on National Forest System (NFS) lands. RNAs are used for non-manipulative research, observation, and study. They also may serve to carry out provisions of special acts, such as the Endangered Species Act and the monitoring provisions of the National Forest Management Act.

Current Situation

Six RNAs were established within the Tongass National Forest prior to 1996. One of the six, Pack Creek, was declassified in the Record of Decision (ROD) for the 1997 Tongass Land Management Plan due to a long history of human presence related to viewing brown bears. At the same time, Pack Creek was re-designated as a zoological area to be managed under the Special Interest Area LUD. Seven additional areas were classified as RNAs by the 1997 ROD. That action resulted in the current total of 12 Tongass RNAs incorporating a total area of 66,059 acres. Brief descriptions of each follow below.

Cape Fanshaw RNA

Established in 1965, this 614-acre RNA is located at the junction of Frederick Sound and the Stephens Passage in Roadless Area 201. This area was established to represent undisturbed old-growth yellow-cedar and western hemlock forests. It represents a good example of cedar decline on the mainland, and has been used for long-term monitoring of changes in species composition and stand dynamics.

Dog Island RNA

Established in 1976, this 705-acre RNA is located on Dog Island in Roadless Area 521. The area represents a small island ecosystem containing the northern limit of

Pacific yew (*Taxus brevifolia*), associated scrub timber, and low-volume, mixed-conifer sites of southern Southeast Alaska.

Kadin Island RNA

Established in 1997, this 1,623-acre RNA is located just north of Wrangell in Roadless Area 225. Kadin Island experiences high winds blowing down through the Stikine River corridor. The high winds pick up silt from the unvegetated glacial river floodplain and cause the deposition of loess on the island at the river's mouth. The continuing rain of loess onto the upper soil layers provides a supply of unleached, nutrient-rich soil material to the forests of the island. The loess deposition overcomes the process of acid bog formation (paludification) that overtakes most stable sites of moderate topographic relief on the Tongass National Forest. Few areas in the world have a combination of high rainfall and recent loess deposition, so the properties of the soils here are of special interest. The fringe of the island is subject to tidal influence and changes in water level because of shifts of the river. Wetland marsh communities are included in this area. The bald eagle nest concentration on Kadin Island is second only to parts of Admiralty Island, according to the U.S. Fish and Wildlife Service.

Marten River RNA

Established in 1997, this 6,213-acre RNA is located within the Misty Fiords National Monument Wilderness adjacent to the Red River RNA. The Marten River RNA contains riparian spruce stands and has excellent habitat for brown bears along its major mainland streams.

Limestone Inlet RNA

Established in 1951 and expanded in 1971, this 9,102-acre RNA is located in Stephens Passage in Roadless Area 302. The area represents typical vegetation types common to the Juneau mainland, including many avalanche chutes and a mainland stream with a good fish population. In 1951, Limestone Inlet was considered the most pristine drainage in the northern mainland coast, making it an excellent area for documenting baseline conditions on the mainland. Alaska Department of Fish and Game has altered the native salmon runs since 1980 by operating a hatchery in nearby Snettisham Lake; however, upland areas remain intact.

Old Tom Creek RNA

Established in 1951, this 4,544-acre RNA is located on central Prince of Wales Island in Roadless Area 519. Situated in a low-site, cedar-dominated watershed, this RNA was established as an example of cedar-hemlock old-growth forest. It also includes some examples of riparian spruce forest, extensive tidal meadows, and dense bald eagle and black bear populations.

Red River RNA

Established in 1980, this 8,031-acre RNA is located in Misty Fiords National Monument Wilderness. This RNA represents the northern range of Pacific silver fir (*Abies amabilis).*

Rio Roberts RNA

Established in 1997, this 1,560-acre RNA is located on central Prince of Wales Island in Roadless Area 511. This area contains riparian flood plain spruce stands, upland old-growth and natural young-growth stands, and upland hemlock on drumlin fields. A high level of recreation use occurs in the area, including hiking, camping, boating, and fishing in the Thorne River near this RNA.

Robinson Lake RNA

Established in 1997, this 4,297-acre RNA is located in the Misty Fiords National Monument Wilderness. This RNA focuses on a natural slump lake, forest types typical of the southern portion of mainland Southeast Alaska, and some uncommon plants of restricted distribution in Alaska. Robinson Lake formed in recent years when a natural earthslide dammed Robinson Creek. The area extends to the shore of Behm Canal in order to include habitat diversity associated with the shoreline and proximity to deep water.

Tonalite Creek RNA

Established in 1997, this 9,515-acre RNA is located south of Tenakee Springs across Tenakee Inlet in Roadless Area 311. This RNA includes pristine examples of Sitka spruce, western and mountain hemlock, and yellow cedar forest types. The Tonalite drainage is a narrow glacial valley that supports runs of pink, chum, and coho salmon. The drainage is prime brown bear, Sitka black-tailed deer, and beaver habitat.

Warm Pass Valley RNA

Established in 1997, this 8,306-acre RNA is located along the U.S.-Canada border between the Taku River and Chilkat Pass in Roadless Area 301; the valley includes the northernmost example of subalpine fir in Alaska. The valley is also an important migration corridor for interior vegetation species that mix with the coastal forest and tundra. The Warm Pass Valley RNA has a very different climate caused by a pronounced rain shadow effect. The valley supports a good population of moose that use both the alpine shrub belt and riparian shrubs at lower elevation.

West Gambier Bay RNA

Established in 1997 to replace the Pack Creek RNA, this 11,549-acre RNA is located at the head of the west arm of Gambier Bay in Admiralty Island National Monument-Kootznoowoo Wilderness. The area includes long, narrow Pybus Lake and several smaller lakes; productive wildlife habitat; an anadromous fish stream; and a variety of geological features, including karst. West Gambier Bay contains forest and nonforest vegetation types typically found on the islands of northern Southeast Alaska.

Special Interest Areas

Special Interest Areas are areas possessing unique or unusual scenic, historic, prehistoric, scientific, natural, or other characteristics. The objective of designating and managing such areas is to protect their unique values and, where appropriate, to foster public use and enjoyment of these areas. Special Interest Areas may be designated as scenic, recreation, historic, archaeological, geological, botanical, zoological, or paleontological areas. Special Interest Areas differ from RNAs in that management may promote public use as well as scientific study.

Special Interest Area designations are intended to maintain natural to near-natural conditions in most cases; the Recreation Area designation may include developed facilities within a natural or near-natural setting. The resources contained within these areas are not available for development, except for public facilities designed to allow recreation use while protecting the values of the area, or for interpretation and scientific study. Each area may require unique management direction determined through individualized study and planning. Special Interest Areas may be withdrawn from mineral entry. The LUD for Special Interest Areas applies to all the designated areas.

Current Situation

Twenty-four Special Interest Areas have been designated within the Tongass National Forest. They occupy a total area of 629,782 acres (it should be noted that many of these acres are sometimes tabulated under another LUD category when the Special Interest Area occurs within a Congressionally designated area, e.g., Wilderness, National Monument, and LUD II). Eight of the 24 areas were designated prior to the 1997 Land Management Plan Revision. These include the following:

- Mendenhall Glacier Recreation Area (5,791 acres)
- Ward Lake Recreation Area (440 acres)
- Walker Cove-Rudyerd Bay Scenic Area (93,540 acres)
- Admiralty Lakes Recreation Area (8,710 acres)
- New Eddystone Rock Geological Area (1 acre)
- Hubbard Glacier Geological Area (46,000 acres)
- Tracy Arm-Fords Terror Scenic Area (283,000 acres)
- Naha Recreation Area (2,363 acres)

The remaining 16 Special Interest Areas, plus 1 expansion, were identified and designated with the 1997 Land Management Plan Revision as the following:

- Arena Cove/Cape Felix Geological Area (9,465 acres)
- Bailey Bay Hot Spring Recreation Area (3,510 acres)
- Blind Slough Recreation Area (8,150 acres)
- Blue River Lava Flow Geological Area (13,520 acres)
- Clear River Zoological Area (11,530 acres)
- Duke Island Zoological Area (44,650 acres)
- Falls Creek Windthrow Botanical Area (820 acres)
- Fish Creek Hotsprings Recreation Area (100 acres)
- Karst Areas Geological Areas (multiple areas totaling 13,635 acres)
- Keku Islet Geological and Scenic Area (2,300 acres)
- Mt. Edgecumbe Geological Area (49,050 acres)
- North Hamilton River Red Cedar Cultural and Botanical Area (80 acres)
- Pack Creek Zoological Special Interest Area (5,837 acres)
- Patterson Glacier Geological and Botanical Area (13,900 acres)

- Pike Lakes Recreation Area (2,340 acres)
- Soda Springs Geological Area (3,515 acres)
- Ward Lake Recreation Area Expansion (7,535 acres)

Eight of the Special Interest Areas have been designated within Wildernesses and/or National Monuments, or LUD II areas. These areas are already managed in a way that accounts for the Wilderness, National Monument, or LUD II area surrounding them. They include the following:

- Admiralty Lakes (Admiralty Island National Monument and Kootznoowoo Wilderness)
- Blue River Lava Flow (Misty Fiords National Monument and Wilderness)
- Hubbard Glacier (Russell Fiord Wilderness)
- Naha Recreation Area (Naha LUD II)
- New Eddystone Rock Geological Area (Misty Fiords National Monument and Wilderness)
- Pack Creek Zoological Special Interest Area (Admiralty Island National Monument and Kootznoowoo Wilderness)
- Tracy Arm-Fords Terror (Tracy Arm-Fords Terror Wilderness)
- Walker Cove-Rudyerd Bay (Misty Fiords National Monument and Wilderness)

Because the National Monument, Wilderness, and LUD II designations recognize and protect the same values for which the areas were originally designated, the Special Interest Area designation may have become redundant, and the possibility of declassifying these areas as Special Interest Areas is being explored by the Forest Service. No proposals for declassification are being made at this time.

The Tongass also contains a small portion of the 5-acre Fort Durham National Historic Landmark (most of which is on private land).

Special Interest Areas are not available for timber harvest, and roads would be allowed only if they are compatible with the interpretive goals of a particular area. Other restrictions may be imposed on a case-by-case basis to protect an area's unique values. These could include closures to off-highway (or off-road) vehicle (OHV) use, and withdrawals from mineral entry. Currently, the Mendenhall Glacier, Ward Lake, and Naha Recreation Areas are withdrawn from mineral entry. The need for such restrictions for newly designated or expanded areas may be determined during Forest Plan implementation.

Wild and Scenic Rivers

This section describes the process for Wild and Scenic River designation, and the rivers on the Tongass National Forest that are currently managed as wild and scenic rivers.

Background

The Wild and Scenic Rivers Act of 1968, as amended, provides a means for recognizing and protecting the "outstandingly remarkable" scenic, recreation, geologic, fish and wildlife, historic, cultural, ecological, and other values of selected rivers. The intent of including a river in the National Wild and Scenic Rivers System is to preserve the free-flowing condition of the river itself, as well as the characteristics of the river's immediate environment for the enjoyment and benefit of present and future generations. The U.S. Congress is responsible for final designation of rivers to be included in the National Wild and Scenic Rivers System.

ANILCA designated 26 rivers in central and northern Alaska as components of the National Wild and Scenic Rivers System under the Wild and Scenic Rivers Act of 1968. No rivers in Southeast Alaska or the Tongass National Forest were designated under ANILCA. An additional 12 rivers were designated as “study rivers” by ANILCA, of which only one, the Situk River near the community of Yakutat, is in Southeast Alaska and in the Tongass National Forest.

The Situk River, including the West Fork and Old Situk Creek, was studied in 1983 and was found to possess outstandingly remarkable fish, wildlife, and recreational values of national significance, but was not recommended for designation. The community of Yakutat, the local and regional Native corporations, the Citizens Advisory Council of Federal Areas, the Governor of the State of Alaska, and the Regional Forester on behalf of the Forest Service, signed an agreement to recognize each others’ responsibility in cooperative management of the Situk River corridor in lieu of designation as a Wild and Scenic River. The Alaska Land Use Council supported development of a management plan for the Situk River, rather than designation as a Wild and Scenic River (USDA Forest Service 1993a)) and the Secretary of the Interior formally determined to not recommend designation of the Situk River. The Situk River corridor continues to be managed through a cooperative process among the signatories to that agreement.

The National Park Service initiated an evaluation to determine the eligibility of the rivers within the National Parks and Preserves in Alaska. The Alsek River near Yakutat is included in that evaluation. The Tongass National Forest includes the surface and west bank of an 18-mile segment that was found to be eligible and meeting a “Scenic” classification.

The analysis and planning that led to the 1997 Forest Plan included a process for identifying rivers that could be eligible for inclusion in the National Wild and Scenic Rivers System. The process started with an inventory and evaluation to determine the eligibility, potential classification, and suitability for inclusion in the National Wild and Scenic Rivers System.

Rivers are eligible to be considered for inclusion in the National Wild and Scenic River System if they are essentially free-flowing (without major dams, diversions, or channel modifications), and if they possess at least one “outstandingly remarkable” scenic, recreational, geologic, fish and wildlife, historic, cultural, or other similar value. These values should be a unique or exceptional representation for the area studied, and must be related to the river or its immediate environment.

The potential classification for each eligible stream segment was done according to the criteria in the Wild and Scenic Rivers Act into either Wild, Scenic, or Recreational Rivers defined as follows:

- Wild River areas are defined as those rivers or sections of rivers that are free of impoundments and generally inaccessible except by trail, with watersheds or shorelines essentially primitive in character and waters unpolluted. These represent vestiges of primitive America.
- Scenic River areas are defined as those rivers or sections of rivers that are free of impoundments with shorelines or watersheds still largely primitive and shorelines largely undeveloped, but accessible in places by roads.
- Recreational River areas are defined as those rivers or sections of rivers that are readily accessible by road or railroad, that may have undergone some development along their shorelines, and that may have undergone some impoundment or diversion in the past.

Eligible rivers are further evaluated for “suitability.” Generally this analysis considers the appropriateness of Congressional designation as a Wild, Scenic, or Recreational

River in light of social and economic values, or the resource opportunities enhanced, curtailed, or foregone, and the effect on private lands and other uses of the area. Suitable rivers may be recommended to Congress by the administration for designation. If designation occurs, a final boundary is established and a management plan developed.

There are nearly 900 watersheds on the Tongass National Forest containing some 42,500 miles of perennial stream. All of the rivers and streams on the Forest were examined and evaluated for eligibility for the National Wild and Scenic Rivers System. An initial evaluation identified 300 rivers and streams for further study. Of these, 112 rivers with 1,394 stream miles were determined to be eligible for consideration as components of the National Wild and Scenic Rivers System. More detail about the process that was used and the individual rivers studied is available in the 1997 Tongass Forest Plan Revision Final EIS.

Based on a suitability analysis, the Regional Forester recommended 32 of the 112 eligible rivers for inclusion in the National Wild and Scenic Rivers System as either Wild, Scenic, or Recreational (Table 3.21-1). Appendix E of the 1997 Tongass Land Management Plan Revision Final EIS provides descriptions of each river. The 1997 ROD contains the rationale for the decision made for each river. The recommendation was a preliminary administrative recommendation that would be forwarded to the Chief of the Forest Service. It could receive further review and possible modification by the Secretary of Agriculture and the President of the United States. Congressional action is necessary to designate rivers as part of the National Wild and Scenic Rivers System.

Because this was a preliminary administrative recommendation, the 1997 Forest Plan directs that the rivers be managed, within the existing authorities of the Forest Service, to retain their free-flowing character and outstandingly remarkable values. Three LUDs were created for these rivers, one for each classification: Wild River, Scenic River, and Recreational River. The 1997 Forest Plan includes goals, objectives, desired conditions, and specific management prescriptions for each LUD. The Wild and Scenic Rivers Act provides that the study boundary includes, at a minimum, the area within 0.25 mile of the ordinary high water mark on each side of the river (USDA Forest Service 1993b). Final boundaries can and do vary from this minimum, but generally follow the 0.25-mile guideline. The area of the recommended rivers managed under the Wild, Scenic, and Recreational River LUDs were determined so as to maintain the eligibility of the total miles of river for each classification.

Subsequent to the Regional Forester's 1997 Wild and Scenic River recommendations, the Acting Forest Supervisor determined that the recommendation for Niblack Lakes and Streams was based on incorrect information related to the anadromous fish productivity of the system. In November 1998, a non-significant of the 1997 Forest Plan rescinded the Wild and Scenic River recommendation and associated LUDs for Niblack Lakes and Streams (USDA Forest Service 1999c); therefore, Niblack Lakes and Streams is not included in this analysis.

Table 3.21-1
Rivers (Segments) Recommended for Inclusion in National Wild and Scenic River Program (in miles)

River Name	Wild	Scenic	Rec.	Outstandingly Remarkable Values: Fish	Wildlife	Recreation	Scenic	Hist./Cult.	Geology	Ecology

Current Situation

Congress has not yet designated any rivers on the Tongass National Forest to be included in the National Wild and Scenic Rivers System.

The goal for management of the rivers that were recommended for Wild and Scenic designations is to maintain their outstandingly remarkable values and their free-flowing conditions. The objective is to manage the 31 rivers (or segments), pending designation by Congress as Wild, Scenic, or Recreational Rivers, to maintain the eligibility of the total miles of river for the Wild, Scenic, or Recreational classification.

The goal is to be achieved through the management of the rivers (or segments) under the LUD of Wild River, Scenic River, or Recreational River and implementation of the standards and guidelines specified for the LUD. These are summarized below and described in more detail in the 1997 Forest Plan.

Wild River LUD. This is the most restrictive of the three LUDs. Scheduled timber harvest and construction of major recreation facilities, roads, and hydroelectric power projects are not allowed. Mining may be allowed or the area may be withdrawn from mineral entry by Congress at the time of designation as a Wild River. Some fish and wildlife habitat enhancement are permitted. This is a Transportation and Utility Systems "Avoidance Area," but corridors will be allowed in accordance with ANILCA, Title XI. Twenty-three river segments, or 359.5 river miles, are currently managed under this LUD.

Scenic River LUD. Hydroelectric power projects are not allowed, but timber harvest is allowed if the adjacent LUD allows timber harvest. Major recreational developments may be compatible with this LUD and minor developments are allowed. The construction of NFS roads is allowed and bridges may occasionally span the river. Mining and some fish and wildlife habitat enhancement are permitted. This is a Transportation and Utility Systems "Avoidance Area" but corridors will be allowed in accordance with ANILCA, Title XI. Twelve river segments, or 87.5 river miles, are currently managed under this LUD.

Recreational River LUD. Although hydroelectric power projects are not allowed, many other management activities are permitted. Timber harvest is allowed if the adjacent LUD allows timber harvest. Major and minor recreational developments and NFS roads that make the river easily accessible are allowed. Mining and some fish and wildlife habitat enhancement are permitted. This is a Transportation and Utility Systems "Avoidance Area," but corridors will be allowed in accordance with ANILCA, Title XI. Seven river segments, or 89 river miles, are currently managed under this LUD.

The LUD(s) for adjacent land can have significant influence on the management of resources inside Wild, Scenic, or Recreational River LUDs. Many of the corridors designated to the Wild River, Scenic River, or Recreational River LUD are narrow and include the width of the river plus 0.25 mile on each side. The most obvious example of the adjacent LUD influence is that the ability to harvest timber in Scenic or Recreational River LUDs is dependent on the management prescription for timber in the LUD(s) of the adjacent land. In a more indirect way, it may influence other resources, such as scenery, recreation, or road building. For example, if the surrounding land is designated Remote Recreation where no new roads are allowed, it is less likely that a road will be proposed for a Scenic or Recreational River area.

Of the 536 miles of recommended Wild, Scenic, or Recreational Rivers, 221 miles of seven rivers, or 41 percent of the river miles in Wild, Scenic, or Recreational River LUDs, are already in areas allocated to Wilderness or National Monument Wilderness. Most of the remaining Wild, Scenic, or Recreational River miles outside of designated wilderness are surrounded by land currently in non-development LUD designations. Although there are differences in specific management prescriptions for each of the LUDs, there are some common directions. In general, timber harvest is not suitable in the non-development LUDs, and new roads are not allowed or are restricted to specific uses. Minor recreational development is consistent with most non-development LUDs and major recreational development is consistent only with Semi-Remote Recreation. Generally, the non-development status and resulting management prescriptions in these adjacent lands may reduce the likelihood of development in the Scenic or Recreational River LUD.

Wild and Scenic Rivers and Wilderness Management

According to the Wild and Scenic Rivers Act, any portion of a component of the Wild and Scenic Rivers System that is within a wilderness shall be subject to the provisions of both the Wilderness Act and the Wild and Scenic Rivers Act. In the case of conflict between the provisions of these Acts, the more restrictive provisions shall apply (USDA Forest Service 1993b). Thus, there are the dual, but overlapping goals of the preservation of the wilderness resources while at the same time preserving the river and its immediate environment. Because the two laws differ somewhat, legislative action should address specific issues in a particular river corridor.

A variety of recreation types are allowed by managing the rivers as Wild, Scenic, or Recreational. Wild River designation is compatible with wilderness designation because they both provide primitive and semi-primitive recreation opportunities. Scenic and Recreational River designations provide other opportunities that are more developed than those allowed in areas designated as Wild River.

Environmental Effects

Direct and Indirect Effects

Experimental Forests

The primary proposed change involving experimental forests under the action alternatives is the recommended replacement of one of the two existing experimental forests with a management unit better suited to this purpose. As indicated in the Affected Environment discussion, the Young Bay Experimental Forest provides limited opportunities for forestry research and has not been used for experimental purposes in recent decades. Therefore, all alternatives except Alternative 5 propose to eliminate the Young Bay Experimental Forest and designate the Cowee-Davies area as a new experimental forest. Alternative 5, No Action, continues the current designations and retains the Young Bay Experimental Forest.

The current Forest Plan provides standards and guidelines to maintain research opportunities within the two existing experimental forests. Those standards and guidelines have been updated for the Forest Plan Amendment, primarily to include protection for sacred sites and to address inventory and interpretation activities for minerals and geologic resources. Those changes would have no substantive effects on resources present within the experimental forest areas, other than to provide updated management direction for protection of sacred sites, minerals, and geologic resources. The updated standards and guidelines would be applied to the experimental forests designated under all of the action alternatives.

The potential effects associated with the land use allocations of the alternatives on existing and proposed experimental forest areas are described below.

Maybeso Experimental Forest

The Maybeso Experimental Forest offers limited opportunities in the near term to design new experiments (except relative to thinning regimes and management of very young second-growth timber) because most of the suitable forest land had been harvested by the 1960s. Monitoring of research plots established in this area some time ago would continue under all alternatives. New experiments could be conducted in the future. If so, they would likely be rather limited in scope and would probably occur in areas that had previously been harvested.

Young Bay Experimental Forest

The Young Bay Experimental Forest has for some time been considered for delisting as an experimental forest because of the vegetative and access conditions that limit the value of the area for research. The primary reason to retain Young Bay as an experimental forest is to maintain options in light of the Alaska Region's Ecosystem Management Strategy. Potential research could include alternative silvicultural systems and/or manipulating vegetation to create desired wildlife habitat conditions.

If or when such research activities are undertaken, any silvicultural activity would likely use a helicopter yarding method with no road construction, and would likely focus on alternatives to clearcutting. Vegetative manipulation for desired wildlife habitat conditions would likely result in small openings or single tree selection harvesting, also using a helicopter with no roads. This type of research activity would be a possible occurrence under Alternative 5.

Under Alternatives 1, 2, 3, 4, 6, and 7, the Young Bay area would no longer be designated as an experimental forest. Under these alternatives, the Young Bay area would be changed to the Semi-Remote Recreation LUD, consistent with the adjacent NFS lands to the northwest on the Mansfield Peninsula of Admiralty Island. While this is a non-development, mostly natural LUD that is nominally more restrictive of management activities than the Experimental Forest LUD, there would actually be little tangible change in management of the area given the lack of research activities conducted in this area under the past designation.

Cowee-Davies Experimental Forest

Alternatives 1, 2, 3, 4, 6, and 7 include changing the LUD of approximately 22,300 acres in the Cowee-Davies watershed to experimental forest and recommending this area for official designation as an experimental forest. This area comprises Value Comparison Units 230 and 240 and is located on the east side of Lynn Canal approximately 40 to 50 miles north of Juneau. The southwestern side of the proposed experimental forest follows the Lynn Canal shoreline but is set back a few miles, and the northern edge abuts the Berners Bay LUD II designation. The current LUD for the proposed Cowee-Davies Experimental Forest is Scenic Viewshed which, like the Experimental Forest designation, is a moderate development LUD. There would be little change in the type and intensity of management activities in this area under the proposed designation compared to current management.

Research Natural Areas

This section focuses on the effects of the alternatives on current RNAs. All seven alternatives include continued RNA designation for the 12 existing RNAs at their current respective acreages. Likewise, none of the alternatives includes proposed designation of any new RNAs. Therefore, none of the alternatives would have any direct effects on RNAs. Any potential effects of the proposal would be indirect effects associated with changes in LUDs in areas adjacent to RNAs.

Table 3.21-2 summarizes the types of LUDs surrounding RNAs under each alternative. Alternatives 1 and 2 are the same with respect to the distribution of LUDs in areas adjacent to RNAs. Both alternatives maintain current management practices that would have little to no effect on 10 of the 12 RNAs. In both cases, the only changes from current management direction are that the Limestone Inlet and Tonalite Creek RNAs would be entirely surrounded by LUDs in the natural setting group, while those areas currently have LUDs in the natural setting, moderate development, and intensive development groups. Alternatives 1 and 2 would slightly reduce the chance that management activities in adjacent areas would indirectly affect research activities in those two RNAs.

LUDs surrounding the 12 RNAs under Alternative 3 are very similar to those currently in effect (Alternative 5) and to what would occur under Alternatives 1 and 2. Limestone Inlet would also be surrounded by natural setting LUDs under Alternative 3, instead of the current mix of natural setting, moderate development, and intensive development LUDs. Both natural setting and intensive development

Table 3.21-2
Summary of LUDs Surrounding Research Natural Areas by Alternative

Research Natural Area	Alternative						
	1	2	3	4	5	6	7
Cape Fanshaw	N	N	N	M	N	N	M
Dog Island	-	-	-	-	-	-	-
Kadin Island	-	-	-	-	-	-	-
West Gambier Bay	W	W	W	W	W	W	W
Marten River	W	W	W	W	W	W	W
Limestone Inlet	N	N	N	M/I	M/I/N	M/N/I	M/N/I
Old Tom Creek	N/I	N/I	N/I	N/I	N/I	N/I	I
Red River	W	W	W	W	W	W	W
Rio Roberts	N	N	N	M/I	N	N	N/M/I
Robinson Lake	W	W	W	W	W	W	W
Tonalite Creek	N	N	N/I	N/I	N/I	N/I	N/I
Warm Pass Valley	N	N	N	N	N	N	N

Note: Letter symbols represent the following: N = Natural Setting LUD group; W = Wilderness LUD group; M = Moderate Development LUD group; I = Intensive Development LUD group.

LUDs would adjoin the Tonalite Creek RNA under Alternative 3 because they do under current management.

Under Alternative 4, management designations would change for some lands adjacent to three of the RNAs. The Rio Roberts RNA would be surrounded by LUDs in the moderate and intensive development groups. This would be a change from current management, under which natural setting LUDs surround the RNA. Similarly, the Limestone Inlet RNA would be surrounded by LUDs in the moderate and intensive development groups, while a natural setting LUD (old-growth habitat) currently abuts the west and south sides of this RNA. Finally, the NFS lands adjacent to the Cape Fanshaw RNA would be changed from a natural setting LUD (old growth) to a moderate development LUD (scenic viewshed). Based on these changes, Alternative 4 would increase the chance that management activities in adjacent areas would indirectly affect research activities in these three RNAs.

Alternative 6 would maintain the current LUDs in areas adjacent to all 12 RNAs. Therefore, Alternative 6 would have no direct or indirect effects on RNAs.

Similar to Alternative 4, Alternative 7 would intensify management designations adjacent to three RNAs. As with Alternative 4, the NFS lands adjacent to the Cape Fanshaw RNA would be changed from a natural setting LUD (old growth) to a moderate development LUD (scenic viewshed). The Rio Roberts RNA would be surrounded by LUDs in the natural setting and moderate and intensive development groups, while under current management only natural setting LUDs surround the RNA. Similarly, the Old Tom Creek RNA would be adjoined by an intensive development LUD (timber production), rather than the current mix of natural and intensive development LUDs. Overall, Alternative 7 would increase the chance that management activities in adjacent areas would indirectly affect research activities in these three RNAs.

The West Gambier Bay, Marten River, Red River, and Robinson Lake RNAs are already part of designated wildernesses, and the management situation for these areas would not change under any alternative. Similarly, the Dog Island and Kadin Island RNAs are surrounded by water and would not be affected by any LUD changes among the alternatives.

The current Forest Plan provides standards and guidelines to preserve areas of ecological importance and maintain research opportunities within the existing RNAs. Those standards and guidelines have been updated for the Forest Plan Amendment, primarily to include consultation and protection for heritage and sacred sites and to address inventory and interpretation activities for minerals and geologic resources. The updated standards and guidelines also direct that designation of motorized routes for OHVs in RNAs is generally not allowed. Those changes would have no substantive effects on resources present within the RNAs, other than to provide updated management direction for protection of sacred sites, minerals, and geologic resources. The updated standards and guidelines would be applied to the RNAs designated under all of the action alternatives.

Special Interest Areas

This section focuses on the effects that each alternative would have on existing or proposed Special Interest Areas. Alternative 5 (No Action) would maintain the 24 existing Special Interest Areas at their current acreages, and would result in no direct effects on these areas. Alternatives 1 through 4 and 6 and 7 would also continue the current designations and acreages for 23 of the 24 existing Special Interest Areas, modify the acreage of one geologic area, and add new geologic Special Interest Areas in nine regions of the Tongass.

Under Alternative 5, the total acreage within Special Interest Areas (outside of Wilderness, National Monument, and LUD II) would remain at approximately 174,000 acres. Under all other alternatives this figure would be approximately 221,000 acres, an increase of 47,000 acres. Alternatives 1 through 4 and 6 and 7 would provide increased management protection for sensitive geologic resources on the Tongass, primarily karst and cave areas, and would result in a reduced chance that these resources would be damaged by development activities.

The proposed acreage reduction among geologic Special Interest Areas involves the Arena Cove/Cape Felix area on Suemez Island. The current boundary of this area includes approximately 9,700 acres; the revised boundary encompasses approximately 7,400 acres, which is sufficient to protect the volcanic features that are the primary interest for this area. This change in the LUD represents a technical adjustment to correct a mapping error from the 1997 Tongass Land and Management Plan.

Increased acreage in proposed Special Interest Area LUDs under Alternatives 1, 2, 3, 4, 6, and 7 reflect both designation of new areas and expansion of existing areas. These changes are summarized as follows:

- Eastern Chichagof Geological Areas – 12 new areas encompassing approximately 23,900 acres, primarily to protect alpine karst areas, except for one that includes the Kook Lake cave system.
- Kosciusko Island Geological Areas – two new areas including approximately 9,400 acres with intense karst development.
- Northern Prince of Wales Geological Areas – three new areas and one expanded area (part of the Karst Areas Geological Area) covering approximately 2,800 acres (adding to 11,100 existing designated acres in this region), primarily to protect several cave systems in karst areas.
- Heceta Island Geological Area – one new area of approximately 4,100 acres that includes a number of karst-related caves.
- North-central Prince of Wales Geological Areas – two new areas including approximately 700 acres with similar cave systems.

- Dall Island Geological Areas – minor reductions to two existing areas (part of the Karst Areas Geological Area), based on improved inventory work on cave systems, and one new area for a net increase of approximately 9,100 acres.
- Big Creek Geological Area – one new area of alpine karst near Big Creek, just south of the West Arm of Cholmondeley Sound on southern Prince of Wales Island, incorporating approximately 2,000 acres.
- Calamity Creek Caves Geological Area – one new area of approximately 200 acres on Revillagigedo Island, to protect the Calamity Creek Caves and associated karst features.
- Blake Channel Geological Area – one new area of approximately 700 acres near Aaron Creek, to protect a karst and cave system.

The current Forest Plan provides standards and guidelines for managing the existing Special Interest Areas. Those standards and guidelines have been updated for the Forest Plan Amendment, primarily to include direction to inventory and manage karst resources and minerals and geologic resources. The updated standards and guidelines also direct that designation of motorized routes for OHVs in Special Interest Areas is generally not allowed. Those changes would have no substantive effects on resources present within the Special Interest Areas, other than to provide additional specific direction for protection of resources in those areas. The updated standards and guidelines would be applied to the Special Interest Areas designated under all of the action alternatives.

The acreage allocated to the existing and proposed Special Interest Areas is believed to be sufficient to include and protect the resources of interest for each respective unit. Therefore, none of the alternatives are expected to result in indirect effects associated with management activities that might occur in LUDs adjacent to Special Interest Areas.

Wild and Scenic Rivers

All seven alternatives include continued Wild, Scenic, and/or Recreational River LUD designation for the 31 existing river segments designated as potential Wild, Scenic, and/or Recreational Rivers under the current Forest Plan, and at their current respective acreages. These river segments would continue to be managed to protect the outstandingly remarkable values that make them eligible for designation as Wild, Scenic and/or Recreational Rivers by Congress. Likewise, none of the alternatives include proposed designation of any new Wild, Scenic, and/or Recreational Rivers. Therefore, none of the alternatives would have any direct effects on the potential future status of any Wild, Scenic, and/or Recreational Rivers. Any potential effects of the proposal would be indirect effects associated with changes in LUDs in areas adjacent to RNAs.

The current Forest Plan provides standards and guidelines for managing the existing Wild, Scenic, and Recreational River LUDs. Those standards and guidelines have been updated for the Forest Plan Amendment, primarily to include consultation protection for heritage and sacred sites and direction to inventory and manage karst resources and minerals and geologic resources. The updated standards and guidelines also direct that designation of motorized routes for OHVs in Special Interest Areas is generally not allowed in Wild River LUDs, but is allowed in Scenic and Recreational rivers. Those changes would have no substantive effects on resources present within the Wild, Scenic, and Recreational River LUDs, other than to provide additional specific direction for protection of resources in those areas. The updated standards and guidelines would be applied to the Special Interest Areas designated under all of the action alternatives.

Management Provisions

The kinds and amounts of activities and changes acceptable within a river corridor depend on whether it was recommended as a Wild, Scenic, or Recreational River and, to some extent, the LUDs of areas adjacent to the river segment. Variations in management restrictions among Wild, Scenic, and Recreational River LUDs are summarized below.

Recreation. The recreational objectives for management of Wild, Scenic, and Recreational River LUDs are substantially different. While the Wild River LUD ROS class is the same as Wilderness, there are small differences in specific implementation guidelines. Wilderness management has much more restrictive management than Scenic and Recreational River LUDs. LUD II management is less restrictive than Wild River or Wilderness, but more restrictive than Scenic or Recreational River.

Timber Harvesting. Timber harvesting and associated roads and log transfer facilities are presently only allowed in the Scenic and Recreational Rivers when they are adjacent to LUDs that allow timber harvest. There are only 13 miles of rivers in this situation. Costs of harvest in the Scenic and Recreational River LUDs may be higher than other LUDs as a result of standards to maintain identified values.

Water Project Development. New diversions, water supply dams, and hydroelectric power development are not allowed under the Wild, Scenic, and Recreational River LUDs.

Transportation and Utility Corridors. All three river designations are in Transportation and Utility System “Avoidance Areas.” Thus, transportation and utility sites or corridors may be located within these LUDs only after an analysis of potential sites shows that there is no feasible alternative outside these LUDs.

Mining. Mineral entry is not denied in Wild, Scenic, or Recreational River LUDs, but it does need to be consistent with the purposes of the LUD so the eligibility for Congressional designation is maintained. Costs of mining in these areas may be higher than in other LUDs as a result of standards to maintain identified river values. Congressional designation of a river as Wild under the national program would then deny mineral entry, subject to valid claims, but would not affect Scenic or Recreational Rivers.

Roads. New road construction is not allowed in the Wild River LUD. Roads are allowed in the Scenic and Recreational River LUDs and bridges can span the river. If road construction is not allowed in the adjacent area, it is less likely that roads would be planned in the river area. Only 13 miles of the river corridors in roadless areas are within LUDs that allow road construction for forest development.

Fish Improvement Projects. Fish habitat improvements are generally more restricted under Wild, Scenic, and Recreational River designations than under Wilderness or LUD II. In the three Wild and Scenic River LUDs, the free-flowing characteristic and outstandingly remarkable values must be maintained, which limits the projects that can be implemented. Weirs and other stream obstructions are either prohibited or discouraged. However, weirs are a tool of state management of fisheries, installed seasonally, and are not considered to be stream obstructions in the same vein as dams and permanent facilities.

Wildlife Habitat Improvements. In Wild, Scenic, and Recreational River designations, the wildlife habitat improvements are limited to those with the objective of protecting or restoring the river resource and enhancing the outstandingly remarkable value. Manipulation of vegetation or improvements, such as fencing or artificial nest structures, would likely be incompatible with Wild classification. Other improvements might be compatible with a Scenic designation, as long as the undeveloped character was maintained. Most improvements would be acceptable in a Recreational classification, consistent with the outstandingly remarkable values.

Area-Specific Considerations

In addition to the general issues for the Forest activities described above, there are specific resource issues associated with some individual rivers (segments).

Aaron, Oerns, Berg Creeks – Approximately 4 miles of Aaron and Berg creeks are within and adjacent to a corridor with known mineral potential for zinc, copper, silver, and lead. The Bureau of Land Management (BLM) lists this area's potential for mineral development at its highest level (USDA Forest Service 1997a). It has a Mineral LUD overlay that encourages mineral development and may allow road building for mining purposes. There are no existing mineral claims on the river corridor, but the claims in adjacent land may require roads through the river corridor. This corridor has been recommended as Scenic or Recreational River, and designation by Congress as such would not deny mineral rights.

Glacial River – This is not an area of identified high mineral potential for known resources, but the upper half of the river is in a Class 3 tract of undiscovered mineral resources, as mapped by the U.S. Geologic Survey (USGS). This area was recommended to be included in the National Wild and Scenic Rivers System as Wild. Congressional designation as a Wild River would close the corridor to mineral entry, subject to valid existing claims.

Gokachin-Mirror-Low-Fish Creeks – The area within and adjacent to the corridor near Gokachin Creek has been identified by the BLM as having high priority for minerals development. There are several unpatented mine claims within the corridor. This area was recommended to be included in the National Wild and Scenic Rivers System as Wild, which, with Congressional action, would withdraw it from mineral entry.

Kadake Creek – The timber sale schedule identifies numerous entries in and adjacent to this corridor. The river was recommended as a recreational river, thus preserving the ability to harvest timber on most of the corridor's 23 miles (USDA Forest Service 1997a).

Kah Sheets Creek and Lake – Approximately 5 miles of this area are in the Wild River LUD, where timber production is not allowed. Approximately 2 miles are in a Scenic River LUD and are adjacent to a Timber Production LUD. Timber production is allowed in those 2 miles.

Orchard Creek and Lake – The lower portion of the river was recommended as Recreational River to allow the construction of the Swan Lake-Lake Tyee transmission line (USDA Forest Service 1997a). The transmission line has since been located outside this area.

Sarkar Lakes – This area is extremely popular for recreation, with an emphasis on fishing (USDA Forest Service 1997a). Portions of it were recommended as Scenic and Recreational Rivers. The area on the south side of Sarkar Cove is known to have potential mineral development. BLM has not identified the area as having high potential for mineral development and no mining claims exist (USDA Forest Service 1997a).

Virginia Lake – USGS estimates the undiscovered mineral resource to have a moderate value. BLM lists this area as having potential for mineral development. There are no existing claims in the river corridor in the Recreational River LUD (USDA Forest Service 1997a). The timber sale schedule identifies two sales for this management area that could occur within and adjacent to this corridor, consistent with the Recreational River prescription (USDA Forest Service 1997a).

Ecological, scenic, and recreational attributes within the Wild, Scenic, and Recreational River LUDs could be indirectly affected by activities permitted within adjacent LUDs. Table 3.21-3 summarizes the types of LUDs adjacent to Wild, Scenic, and Recreational River LUDs under each alternative.

For most of the river segments, all seven alternatives are identical with respect to the LUDs for lands adjacent to the rivers. Six of the river LUDs (Blue River, Chickamin River, Hasselborg River and Lakes, King Salmon River, LeConte Glacier and Petersburg Creek) are within designated wilderness areas. Similarly, five river LUDs (Anan Creek, Kadashan River, Lisianski River, Naha River, and Salmon Bay Lake and Stream) are entirely or predominantly within LUD II areas. Aside from these river segments within Congressionally designated units, lands adjacent to nine other Wild, Scenic, or Recreational River LUDs remain the same for all seven alternatives. In almost all cases, these adjacent LUDs are in the mostly natural setting LUD group.

Differences among the alternatives with respect to LUDs adjacent to Wild, Scenic or Recreational Rivers apply to 11 of the river LUDs. In most cases, Alternatives 1 and 2 would result in more lands adjacent to river segments in natural setting LUDs. Alternative 7 and, to a lesser extent, Alternative 4 would result in more extensive areas of moderate and intensive development LUDs adjacent to river segments.

Table 3.21-3
LUDs Adjacent to Wild, Scenic, and Recreational Rivers by Alternative

River Name	Alternative						
	1	2	3	4	5	6	7
Aaron, Oerns, Berg Creeks	N	N	N	N	N	N	N
Anan Creek	N	N	N	N	N	N	N
Blind River	N	N	N	N	N	N	N/M

Virginia Lake and Creek	N	N	M	M	M	M	M
Wolverine Creek-McDonald Lake	N	N	I	N	N	N	N

Note: Letter symbols represent the following: N = Natural Setting LUD group; W = Wilderness LUD group; M = Moderate Development LUD group; I = Intensive Development LUD group.

Cumulative Effects

There would be no change in the number of units or acres with RNA or Wild, Scenic, or Recreational River LUDs under any of the alternatives. As a result, there would be no cumulative effects associated with these types of special LUDs under the Forest Plan Amendment. With respect to both Experimental Forests and Special Interest Areas, Alternative 5 would maintain the current acreage within these LUDs, while all other alternatives would recommend increases in the acreage. The net effect of these proposed changes would be a minor increase in the total acreage within mostly natural setting LUDs, and a slight decrease in the extent of developmental activities within the Tongass. As a result, there would be no cumulative effects associated with special LUDs under Alternative 5, and a slightly reduced potential for cumulative effects to Tongass resources under all other alternatives.

This page is intentionally left blank.

Economic and Social Environment

Affected Environment

Introduction

The Tongass National Forest stretches roughly 500 miles from Ketchikan in the southeast to Yakutat in the northwest and includes approximately 80 percent of the land area in Southeast Alaska. The region is sparsely settled with more than 70,000 people living in 32 towns and villages located in and around the Forest. The communities of Southeast Alaska depend on the Tongass National Forest in various ways, including employment in the wood products, commercial fishing and fish processing, recreation, tourism, and mining and mineral development sectors. Many residents depend heavily on subsistence hunting and fishing to meet their basic needs. In addition, natural amenities, subsistence resources, and recreation activities associated with the Tongass National Forest form an important part of the quality of life for many residents of Southeast Alaska. Since there is very little private land in the region to provide these resources and opportunities, appropriate management of the Tongass National Forest is extremely important to local communities and the overall regional economy.

The Tongass National Forest is also an important national and international resource, with an estimated 948,000 cruise ship passengers visiting Juneau in 2005 (McDowell Group 2005), representing a 48 percent increase since 2000. For many, a visit to the Tongass is a once-in-a-lifetime experience and the spending by these visitors drives the recreation and tourism sector, which is the largest natural resource-based sector in the regional economy. The Tongass National Forest contains large areas of essentially undisturbed forest lands, which represent increasingly scarce and, therefore, increasingly valuable ecosystems. These lands have value for many people who may never visit Southeast Alaska, but benefit from knowing that the Tongass National Forest is there. This type of value, often referred to as non-use value, includes existence, option, and bequest values. These values represent the value that individuals obtain from knowing that the Forest exists, knowing that it would be available to visit in the future should they choose to do so, and knowing that it would be left for future generations to inherit.

The economic and social assessment prepared for this EIS is divided into two main sections: 1) Regional and National Economy, and 2) Subregional Overview and Communities. This section—*Economic and Social Environment*—evaluates the potential regional and national economic impacts. The next section—*Subregional Overview and Communities*—also assesses impacts to the economic and social environment, but at the subregional and community level.

Southeast Alaska is divided into five boroughs and three census areas. The five boroughs correspond with the county governments found elsewhere in the United States. Three of these boroughs, Juneau, Sitka, and Yakutat, are city/boroughs. The other two, Ketchikan Gateway and Haines, have independent incorporated communities within their boundaries. The remaining areas that are not part of a borough are allocated to three census areas: Prince of Wales-Outer Ketchikan, Skagway-Hoonah-Angoon, and Wrangell-Petersburg. While census areas are only statistical units, they are widely recognized from a data reporting standpoint by federal agencies and most state agencies as county equivalents.

More than 70,000 people live in the towns, communities, and villages of Alaska's southeastern panhandle, most of which are located on islands or along the narrow coastal strip. Only four of Southeast Alaska's 32 communities met the U.S. Census Bureau's 2000 definition of an urban cluster (population greater than 2,500) in 2005 (Juneau, Sitka, Ketchikan, and Petersburg). Juneau, which is the state capital and a regional trade center, accounted for 43 percent of Southeast Alaska's total population in 2005 (Alaska Department of Labor [DOL] 2006a). Ketchikan Gateway Borough, the second largest borough in Southeast Alaska, accounted for about 19 percent of the region's population in 2005. Ketchikan is a smaller regional trade center that serves Prince of Wales Island and the surrounding area. Population is discussed in more detail in the *Subregional Overview and Communities* section of this EIS.

The remote nature of the region is reflected in a population density of approximately two persons per square mile, which is much lower than the United States' average of 80 persons per square mile. Population densities by borough/census area in 2000 ranged from 0.4 in the Skagway-Hoonah-Angoon census area to 11.4 in Ketchikan Gateway Borough (U.S. Census Bureau 2001). Many locations are accessible only by boat or plane, and landing strips or seaplane facilities are located in virtually all communities. The Alaska State ferry system transports people and vehicles between several ports in Southeast Alaska, and Prince Rupert, British Columbia, and Bellingham, Washington. Haines and Skagway, at the northern end of the Forest, and Hyder at the southern end, offer access to interior and Southcentral Alaska via the Alaska Highway, and Canada via the Cassiar Highway.

The following sections provide an overview of the social and economic conditions in Southeast Alaska and provide a baseline against which the potential effects of the proposed alternatives are measured.

Regional Economic Overview

The Tongass National Forest plays an important role in the formal and informal economies of Southeast Alaska. The formal economy includes those economic activities that are recorded in official statistics. The informal economy includes activities that are not typically recorded in official statistics, such as subsistence, in-kind contributions, non-cash income, unpaid labor and labor exchanges, and care giving to the young and old (Ratner 2000).

Summary economic data are presented for Southeast Alaska for 1996 and 2005 in Table 3.22-1. Annual rates of growth are presented for this period. These data indicate that employment in Southeast Alaska increased by approximately 2 percent over this period (Table 3.22-1). Data compiled by the Alaska DOL indicate that employment in Southeast Alaska has fluctuated over the last decade with a year of job growth often followed by a year of net job loss (Gilbertson 2006).

Adjusted for inflation, total personal income in Southeast Alaska was almost the same in 2005 as it was in 1996 ($2,598 million versus $2,587 million). Total personal income in Alaska and the U.S. increased over this period with respective annual growth rates of 2.2 percent and 2.7 percent. Per capita income in Southeast Alaska was higher in 2005 than 1996, but increased at a slower rate than the Alaska and U.S. averages. Average earnings per job in Southeast Alaska, adjusted for inflation, were 7 percent lower in 2005 then 1996, a decrease of 0.8 percent per year, compared to state and U.S. annual growth rates of 0.2 percent and 1.4 percent over the same time period (Table 3.22-1).

Per capita income in Southeast Alaska was similar to the statewide average in 2005, and six percent higher than the national average. Average earnings per job, which were higher than the national average in 1996 were lower in 2005, with average earnings per job in Southeast Alaska equal to 88 percent of the national average (Table 3.22-1). The region's unemployment rate (7.9 percent) was higher than the state (6.9 percent) and national (5.1 percent) averages in 2005.

Table 3.22-1
Southeast Alaska Economic Overview

	SE AK		1996 to 2005			
	1996	2005	SE AK Percent Change	SE AK Growth Rate (%)	Alaska Growth Rate (%)	U.S. Growth Rate (%)

Notes:
SE AK = Southeast Alaska
1. Income and earnings figures for 1996 are adjusted for inflation and presented as the amount they would be worth in 2005.
2. Full and part-time employment includes self-employed workers. Employment data are by place of work, not place of residence, and therefore include people who work in Southeast Alaska but do not live there. The nonresident share of total private employment in Southeast Alaska was estimated to be approximately 28.1 percent in 2004 (Hadland et al. 2006). Employment is measured as the average annual number of jobs, full-time plus part-time, with each job that a person holds counted at full weight.

Source: Alaska DOL 2007a, 2007b, 2007c; U.S. Department of Commerce, Bureau of Economic Analysis 2007a, 2007b, 2007c, 2007d; U.S. Department of Labor, Bureau of Labor Statistics 2007

Southeast Alaska employment is summarized by sector in Table 3.22-2. State and local government, consumer services, and retail trade were the largest employers in 2001 and 2005, accounting for 21, 14, and 12 percent of total employment in 2005, respectively. Total employment increased by about 1,630 jobs or 3 percent between 2001 and 2005, with self-employed workers (proprietors) accounting for 66 percent of this increase. The largest increases in absolute terms were in the health care (1,235 jobs), retail trade (510 jobs), and real estate and rental and leasing (444 jobs) sectors. The largest absolute decreases occurred in the construction (-346 jobs) and the professional and technical services (-242) sectors. These gains and losses were not evenly distributed throughout the region, as discussed in the *Subregional Overview and Communities* section.

[1] See Table 3.22-1, note 2.
[2] Nine 2-digit North American Industry Classification System (NAICS) categories are combined into these three divisions for ease of presentation. Consumer service includes: other services; arts, entertainment, and recreation; and accommodation and food services. Producer services includes: information; professional and technical services; management of companies and enterprises; and administrative and waste services. Social services includes: educational services; and health care and social assistance.
[3] The location quotient is a relative measure of industry specialization that compares the percentage of employment concentrated in each sector in the study region with a benchmark region, in this case the State of Alaska. A location quotient of 1.0 indicates that the study region has the same percentage of employment in this sector as the benchmark region does. Location quotients above or below 1.0 indicate that the study region is over or under represented in this sector, respectively.
Source: U.S. Department of Commerce, Bureau of Economic Analysis 2007b.

The location quotients in Table 3.22-2 (see note 3) compare the regional employment distribution with the state average and indicate Southeast Alaska's economy is specialized in the state and local government and retail trade sectors (Table 3.22-2). The relative concentration in the government sector largely reflects the location of the state capital in Juneau, but the relatively high proportion of government employment in the other Southeast Alaska communities also plays a part. With the exception of manufacturing, transportation and warehousing, and consumer services, which have location quotients of 1.0, all other sectors in Southeast Alaska are relatively underrepresented.

The government sector is the main source of year round employment in all the communities in Southeast Alaska. In addition to direct employment in the government sector, many of the area's private sector jobs are also dependent on government funding and contracts. Private sector activities dependent on government funding include road construction and even health services, with the region's largest private employer, Southeast Alaska Regional Health Corporation, relying heavily on government funding (Gilbertson 2004).

Recreation and tourism are heavily represented in the economy of Southeast Alaska. This is not readily apparent from Table 3.22-2 because recreation and tourism-related activities are distributed over a number of standard economic sectors, mainly retail trade and consumer services. The percent of the total workforce that is self-employed in Southeast Alaska is slightly higher than the state average, 24 percent compared to 22 percent (location quotient of 1.1), and higher than the national average of 19 percent. Much of this self-employment is associated with the retail trade and consumer services sectors and is sensitive to recreation and tourism activity. Commercial fishing also accounts for a large share of self-employment in Southeast Alaska.

The following section discusses the relative contribution of natural resource-based industries to the regional economy, and more specifically those industries that could be potentially affected by the proposed alternatives.

Natural Resource-Based Industries

Overview

Wood products, recreation and tourism, and mining are the primary natural resource-based industries that could be affected by the alternatives. The following discussion focuses on these industries, but also provides summary information on commercial fishing and seafood processing to provide a more complete overview of the contribution of natural resource-based industry to the regional economy of Southeast Alaska.

In most cases, the employment, income, and revenue figures derived for these industries required a series of steps, each involving assumptions and potential sources of error. Where possible, these assumptions are stated and the nature of the associated problems discussed.

Direct Employment

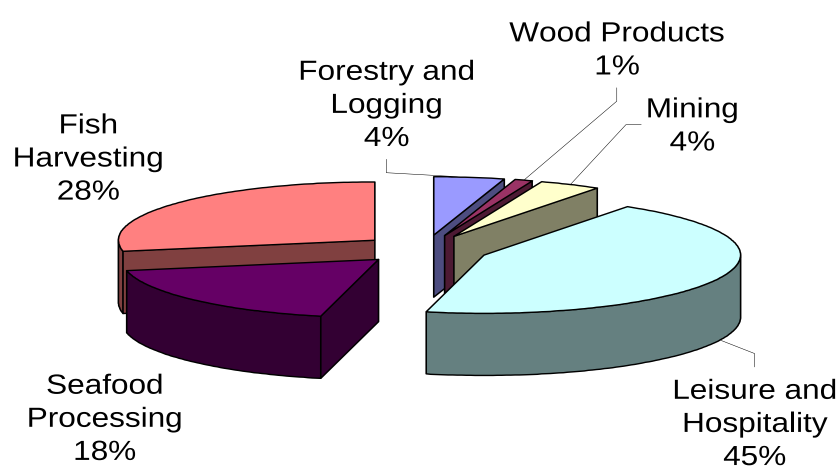
Direct employment in natural resource-based industries accounted for 21 percent of total employment in Southeast Alaska in 2005 (Table 3.22-3). The distribution of resource-dependent employment is shown by industry in Figure 3.22-1. The leisure and hospitality sector, used here to represent recreation and tourism, accounted for 45 percent of direct resource-dependent employment in 2005. Fish harvesting and seafood processing accounted for an estimated 28 percent and 18 percent, respectively. Forestry and logging and wood products together accounted for 5 percent of natural resource employment, with mining accounting for the remaining 4 percent (Figure 3.22-1).

Table 3.22-3
Natural Resource-Based Industry Employment, 2005

Industry	2005 Direct Employment	Direct Employment as a Percent of SE Alaska Total[4/]	2005 Total Employment	Total Employment as a Percent of SE Alaska Total
Forestry and Logging	351	1%	674	2%
Wood Products	105	0%	219	1%
Mining	312	1%	462	1%
Leisure and Hospitality[1/]	3,586	9%	4,339	11%
Seafood Processing	1,500	4%	2,460	6%
Resource Dependent Total[2/]	5,854	15%	NA	NA
Total Wage and Salary Employment[3/]	**36,700**	94%	**36,700**	93%
Fish Harvesting (proprietors)	2,281	6%	2,806	7%
Southeast Alaska Total[4/]	**38,981**	**100%**	**39,506**	**100%**

1/There are no recent available estimates of recreation and tourism employment available for Southeast Alaska. The Leisure and Hospitality sector is used here as a relative indication of the importance of this industry. This sector includes the Arts, Entertainment, and Recreation and Accommodation and Food Services sub-sectors.
2/There is no total provided for 2004 Total Employment because indirect employment for the seafood processing sector includes salmon harvesting and summing the totals for these sectors would result in some salmon harvesting employment being double counted.
3/This total and the direct employment numbers for the above sectors represent non-agricultural wage and salary employment and do not include proprietors or self-employed workers.
4/This total includes proprietors employment for the fish harvesting sector only.
Sources: Alaska DOL 2006a, 2006b, 2007d.

Figure 3.22-1
Direct Resource-Dependent Employment by Sector 2005



Total = 8,135 Employees (Average Annual Employment)
Source: see Table 3.22-3

Total Employment and Earnings

Economic activity in one sector generates activity in others as firms purchase services and materials as inputs (termed "indirect" effects) and employees spend their earnings within the local economy ("induced" effects). In what is known as the multiplier effect, each industry possesses a multiplier that represents its impact on the regional economy given its particular distribution of local purchases and payments. The total effects (i.e., direct, indirect, and induced) generated by an industry are calculated by multiplying employment within that industry ("direct" effects) by the appropriate multiplier.

The analysis presented in this EIS uses industry-specific multipliers to assess the total employment and income effects of the alternatives. These multipliers are also used to estimate total natural resource-based employment in 2005 (Table 3.22-3). The multipliers used in this analysis are presented in Table 3.22-4. These multipliers were estimated using IMPLAN, an input-output model commonly used in this type of application. Total employment and income estimates derived using these multipliers include both indirect and induced effects.

Table 3.22-4
Employment and Income Multipliers

	Employment	Income
Sawmills	2.09	1.51
Logging	1.92	1.39
Mining	1.48	1.25
Recreation and Tourism	1.21	1.32
Salmon Harvesting	1.23	2.37
Seafood Processing	1.64	1.32

Notes:
1. These multipliers were estimated using the 1998 IMPLAN model.
2. The multipliers shown in this table are for total (direct, indirect, and induced) employment or income. Ten direct sawmill jobs would, for example, result in total (direct, indirect, and induced) employment of approximately 21 jobs.

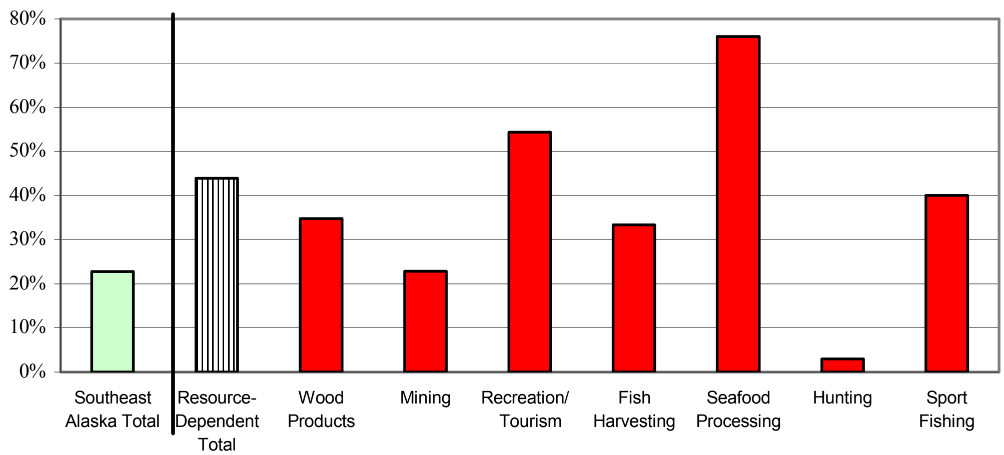
The software and databases necessary to run IMPLAN are available commercially from the Minnesota IMPLAN Group. The IMPLAN system adjusts national level data to fit the economic composition and estimated trade balance of a chosen region and can be used to construct county or multi-county models for any region in the United States. The model used for this analysis consists of the boroughs and census areas that comprise Southeast Alaska. The data used to estimate the multipliers in Table 3.22-4 were obtained from standard data sets produced and maintained by the Minnesota IMPLAN Group. Concerns have been raised with respect to the ability of IMPLAN and similar input-output models to accurately predict indirect and induced effects. Alternate techniques for estimating these effects are, however, subject to the same, or similar, criticisms and more accurate estimates are not readily available for this analysis. While the multipliers presented here should be viewed with caution, the resulting estimates of indirect and induced employment provide a basis for comparison between alternatives.

The estimates of resource-dependent employment shown in Figure 3.22-1 are only for direct employment and, as a result, do not fully illustrate the role that resource-dependent industries play in the regional economy. Adding indirect and induced employment effects alters the relative contribution of the various sectors because employment multipliers vary by industry, but provides a more complete picture of the economic importance of resource dependent industries. The relative contribution is also different when measured in terms of income because wage rates vary by sector, with higher average wages paid in the mining and wood products sectors. Total employment estimates are presented in Table 3.22-3 to provide perspective on the overall contribution of natural resource-based industries to the region's economy, as well as the relative significance of each sector.

Nonresident and Seasonal Employment

Nonresident and seasonal employment are two important and related aspects of resource-dependent employment in Southeast Alaska. Nonresident employment shares are shown for each resource-dependent industry and the region as a whole in Figure 3.22-2. Nonresident workers accounted for 44 percent of employment in the resource-dependent sector as a whole in 1994, approximately twice the regional average. Seafood processing and recreation and tourism had the largest nonresident shares, but all of the resource-dependent industries, with the exception of guided hunting, had nonresident shares above the regional average. Many nonresidents work a relatively short time in Alaska, often for just 2 or 3 months, generally spend the bulk of their earnings elsewhere, and, as a result, contribute less to the regional economy than resident workers.

Figure 3.22-2
1994 Nonresident Share of Direct Employment in Southeast Alaska, Total and Resource-Dependent Industries



Note: All employment figures are standardized to annual average employment.
Source: USDA Forest Service 1997a (Figure 3-16).

Figure 3.22-2 was prepared for the 1997 Forest Plan EIS using data compiled by the Alaska DOL. More recent comparable data are not available. However, statewide nonresident data suggest the nonresident shares shown in Figure 3.22-2 are generally representative of current patterns. Seafood processing had the highest percentage of nonresident workers in Alaska in 2004, with almost three quarters of the labor force (72 percent) comprised of nonresidents. This is comparable with the 1994 data, which showed that 75 percent of workers in the seafood processing sector in Southeast Alaska were nonresidents. Similarly, statewide in 2004, nonresident workers comprised 33 percent of statewide employment in the logging and wood products sector in 2004, compared to 35 percent in Southeast in 1994 (Hadland et al. 2006).

Nonresidents accounted for approximately 28.1 percent of private sector employment in Southeast Alaska in 2004, compared to 21.3 percent for the state as a whole. Within Southeast Alaska, the nonresident share of employment ranged from 18.9 percent in Juneau to 44.3 percent and 49.7 percent in Haines and Skagway-Hoonah-Angoon, respectively. The relatively low level of nonresident employment in Juneau reflects the importance of the government sector, which accounted for 42 percent of employment in Juneau in 2005 (Alaska DOL 2006b).

Average annual seasonal variations in employment are shown for resource-dependent industries and the region as a whole in Figure 3.22-3. As shown in this figure, seasonal variations in resource-based employment—the difference between peak levels of employment in the summer and dips in the winter—are often quite pronounced. The measure shown in the figure is calculated by dividing the difference between summer maximum and winter minimum employment by annual average employment. Expressed as a percentage, this figure allows comparison between different industries and the regional economy as a whole. Seafood processing shows a very high degree of seasonal variation. Data for 2000 through 2004 for salmon harvesting are not shown in Figure 3.22-3, but using the same measure show an annual degree of seasonal variation that is slightly more than twice the variation for seafood processing, with employment ranging from about 100 people in January to as many as 18,700 in July (Patton and Robinson 2006).

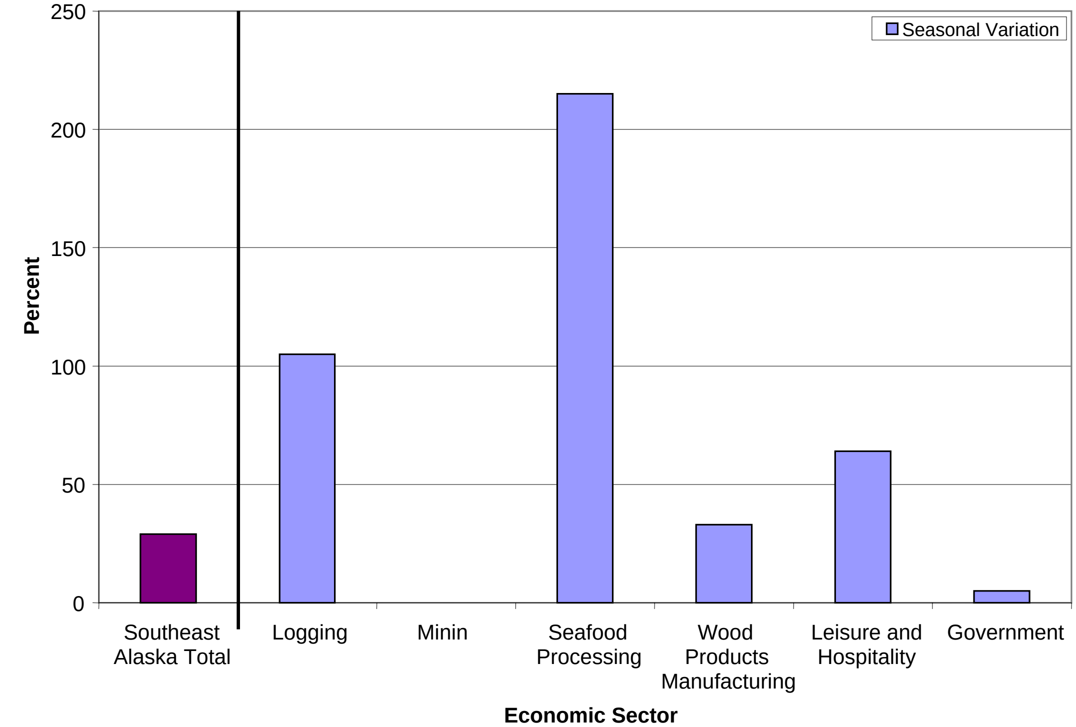
Although not reported here, it is safe to assume, based on the distribution of visitors throughout the year among other things, that recreation and tourism also shows a high degree of seasonal variation. Data are presented for the Leisure and Hospitality sector in Figure 3.22-4 as a proxy for recreation and tourism and show a degree of variation substantially lower than the salmon harvesting and seafood processing sectors, but more than twice the Southeast Alaska average. Data for the logging sector also show a high degree of seasonal variation; about half the variation for the seafood processing sector. Seasonal variation for wood products manufacturing was generally comparable with the Southeast Alaska average. The mining sector showed no seasonal variation, with 300 people reported in this sector for the entire three year period that data are available. Data are also presented for the government sector, which showed much less seasonal variation than the Southeast Alaska average (Figure 3.22-4). There is, however, some variation by type of government employment, with the seasonal variation for federal government employment more than twice the variation for state and local government, but still less than the Southeast Alaska average.

These data indicate that much of the employment in resource-based industries in Southeast Alaska is seasonal and typically relies on a transient labor force. Communities that rely on this type of employment often have difficulty attracting other service providing industries that rely upon year round customers. Gilbertson (2004) suggests that Juneau has experienced relatively large private sector growth over the last decade or so because the stable year round government employment there attracts service providing industries. This is not, unfortunately, the case with many smaller Southeast Alaska communities.

Industry-Specific Descriptions

The following subsections contain more detailed descriptions of each resource-dependent industry.

Figure 3.22-3
Average Annual Seasonal Variation in Employment 2001-2005 (percent)



Notes:
1. Average seasonal variation is calculated here by dividing the difference between summer maximum and winter minimum employment by annual average employment. The resulting measure is expressed as a percentage.
2. The estimates for logging and mining are based on three years data only (2001 to 2003). The wood products manufacturing estimate is based on just two years (2001, 2002). The other estimates are based on five years of data (2001 to 2005).
3. There was no seasonal variation in mining employment during 2001 through 2003.
4. Data for the salmon harvesting sector are available for 2000 through 2004. These data are not included in the graph because the degree of annual seasonal variation is an estimated 447 percent, slightly more than twice the variation for seafood processing.
5. Data for the Leisure and Hospitality sector are used here to represent the Recreation and Tourism sector.
Source: Alaska DOL 2006a, Patton and Robinson 2006

Wood Products

Overview

Direct employment in the wood products industry declined dramatically from its peak of 3,543 jobs in 1990 to 456 jobs in 2005, accounting for approximately 1 percent of total regional employment in 2004. Much of this job loss was associated with closure of the large pulp mills in Sitka (1993) and Ketchikan (1997), which collectively accounted for 899 jobs in 1990. These pulp mills accounted for about half of the federal timber harvest from 1970 up until their closure and also processed much of the chip by-products (manufacturing residues) from the region's sawmills over this period. Closure of the pulp mills had a major effect on the regional demand for timber and the market for wood chips, which has directly affected the region's remaining sawmills.

A larger absolute decline in wood products employment over this period occurred in the logging sector with a net decline of 1,842 jobs over the same period, a decrease from 2,144 jobs in 1990 to just 302 jobs in 2004. This decline in logging employment partly occurred due to a reduction in harvest from the Tongass National Forest, with annual harvest declining from 471 million board feet (MMBF) in 1990 to 46.3 MMBF in 2004, but large reductions in annual harvest also occurred on private lands, with annual private harvests declining from 506.1 MMBF to 98.9 MMBF over the same period.

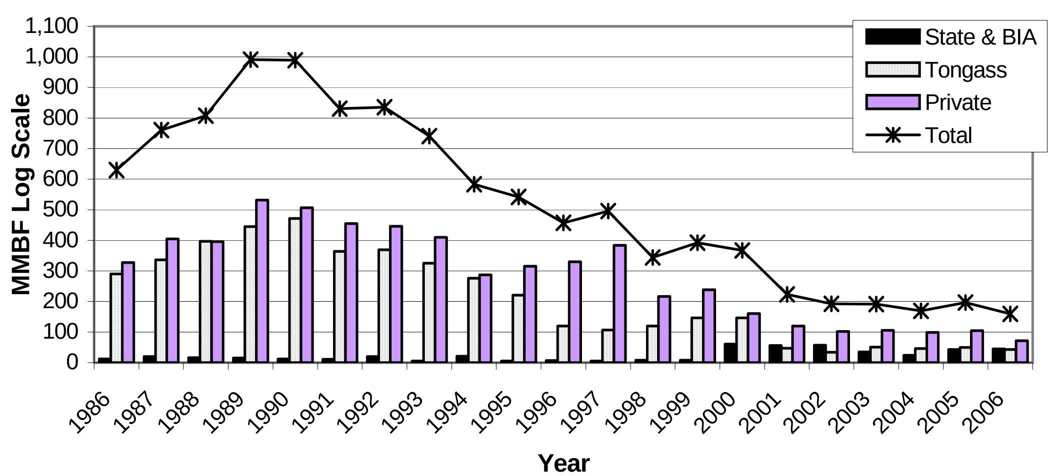
There have been major shifts in markets served by Alaska sawmills over the past decade. Up to 95 percent of production was exported to Japan prior to 1997. Foreign exports have fallen since 2000 and the proportion of volume shipped to domestic markets in the lower 48 states has increased, ranging from 60 percent to 83 percent of total production. Shipments to domestic markets are primarily shop lumber or niche specialty products. Western hemlock is the main species processed by Alaska mills, accounting for 50 to 56 percent of total production (Brackley et al. 2006a). Sawn wood products, like any other commodity, will be sold in the markets that create the most profit for the seller. Domestic markets for Southeast Alaskan sawn wood products are often more attractive at present than foreign markets. Changes in demand, prices, and cost structures have had dramatic effects on the Southeast Alaskan timber industry and on the profitability of the remaining facilities.

Harvest

Timber harvest within Southeast Alaska is the main source of raw materials for the region's wood products industry. Raw material imports averaged just two percent of Southeast Alaska's total round wood consumption from 1983 through 1994 and there have been no notable saw log or utility log imports into the region in recent years (USDA Forest Service 2007d). The Ketchikan veneer mill restarted in 2007 using timber imported from British Columbia. More recently, the mill has acquired timber from a logging contractor that purchased timber from several Southeast Alaska timber sales (Brackley and Haynes, in press; Damstedt 2007). Annual Southeast Alaska timber harvest is shown by landowner for 1986 through 2005 in Figure 3.22-4. Total harvest levels ranged from peak levels of just under 1,000 MMBF in 1989 and 1990 to a low of 169 MMBF in 2004. Total annual harvest increased to about 197 MMBF in 2005, with an increase in harvest on State lands accounting for much of this increase. Total harvest decreased in 2006, with much of the decline (33 MMBF) attributable to further reductions in harvest on Native Corporation lands (USDA Forest Service 2007d).

The overall pattern of harvest levels shown in Figure 3.22-4 generally reflects broader trends in the wood products market. These include the global recession in the wood products industry that depressed output in the early to mid 1980s, the following boom, and the subsequent decline. In Southeast Alaska, harvest levels have shown an overall pattern of decline since 1990 (Figure 3.22-4).

Figure 3.22-4
Southeast Alaska Total Timber Harvests by Ownership, 1986-2006



Notes: Harvests from Alaska Mental Health Trust and University of Alaska lands omitted prior to 2000.
BIA = Bureau of Indian Affairs
Source: USDA Forest Service 2002a, 2007d

The majority of the region's harvest has historically come from two ownerships: the Tongass National Forest and Native corporation (private) lands. Prior to 2000, harvest from these two ownerships ranged from 96 percent to 99 percent of total harvest in Southeast Alaska. The combined Tongass and Native corporation share dropped to 83 and 76 percent in 2000 and 2001, respectively, with the inclusion of the Alaska Mental Health Trust and University of Alaska harvests as part of the state total (Figure 3.22-5). Harvest from the Tongass and Native corporation lands comprised 78 percent of total harvest in 2005. Harvest from Native corporation lands accounted for the majority of this, with harvest from the Tongass accounting for 25 percent (49.5 MMBF) of the total. Harvest from state lands since 2000 has ranged from 59.9 MMBF in 2000 to 24.2 MMBF in 2004, with a total of 42.9 MMBF harvested from state lands in 2005. Most timber harvested from state lands is processed in Alaska. In recent years the state has sold above its annual projected harvest levels to help bridge the gap between national forest harvest and local industry needs.

Timber harvested from the Tongass and Native corporation lands largely flows into different markets which are not solely driven by price. In the case of the Tongass National Forest there are restrictions on shipments of raw materials that dictate how and to whom products can be sold. Yellow-cedar for example can be exported into foreign markets while western redcedar is appraised for local manufacture. Much of the Sitka spruce and western hemlock is processed locally, although under certain circumstances, those species can be shipped out of state. Low grade and small diameter Sitka spruce and western hemlock are appraised for shipment to markets in the lower 48 U.S. states. Once a timber sale is purchased, under certain circumstances, the purchaser can apply for a permit to ship logs to markets other than those they were appraised for. From 2001 to 2006, an average of 19 percent of the total volume harvested on the Tongass has been shipped in whole log form to domestic markets in other states or exported to foreign markets. Levels fluctuated greatly from year to year over this period, ranging from a low of 8 percent to a high of 39 percent. Virtually all of timber harvested on Native corporation land is sold as whole log exports.

Production and Employment

The 1997 Forest Plan EIS (USDA Forest Service 1997a) noted that log exports comprised 43 percent of total Southeast Alaska production on a volume basis from 1981 to 1995. At 36 percent of the total, pulp was the second largest production component over this period and far more stable than log exports. Lumber was noted as the smallest component of total production, averaging 19 percent of the total from 1981 to 1995. The Ketchikan Pulp Corporation (KPC) pulp mill closed in 1997 and brought pulp production in the region to an end. Since 2000, logging has comprised 70 percent of timber sector employment with sawmill employment accounting for the remaining 30 percent.

In 2000 the total annual active sawmill processing capacity in Southeast Alaska was 340 MMBF. A total of 87 MMBF was processed that year, utilizing 26 percent of the existing active capacity. Total active capacity has since declined to around 250 MMBF and the volumes processed from 2003 to 2006 ranged from 31 MMBF (2004) to 34 MMBF (2005), and 12 to 13 percent of total capacity (Brackley et al. 2006b, Juneau Economic Development Council 2006, 2007).

Employment in the Southeast Alaska wood products sector has declined substantially since the peak of 1990 (see Figure 3.22-6), decreasing by 3,093 jobs, or 87 percent, between 1990 and 2004. While this total includes the entire pulp mill labor force, which accounted for 899 jobs in 1990, a larger absolute loss occurred in the logging sector, with 1,842 jobs lost between 1990 and 2004. A total of 456 people were employed in the wood products sector in 2005. Wood products-related indirect and induced employment was estimated at 437 jobs, resulting in a total of 893 jobs supported by the wood products industry in that year (Table 3.22-3).

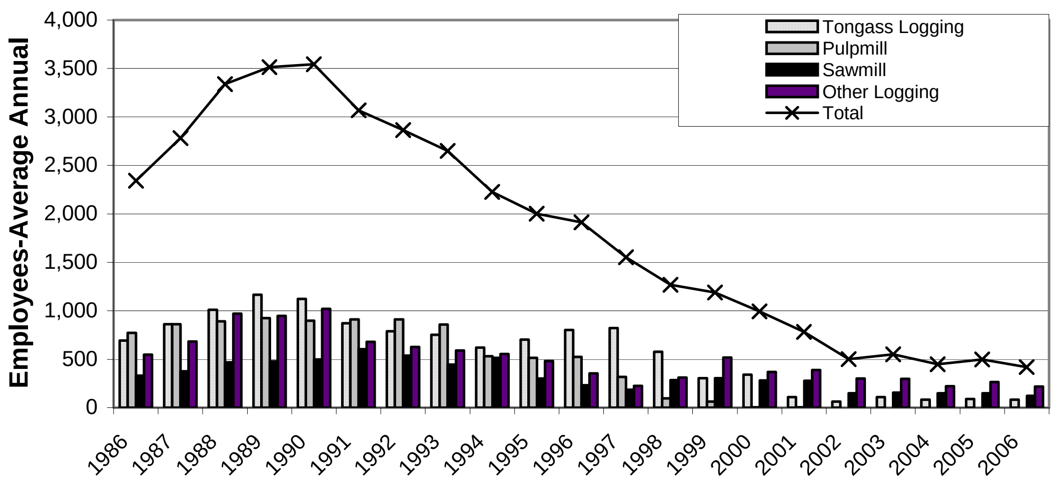
Employment increased slightly in 2005, with a total of 499 people employed in the wood products sector. Logging and sawmills accounted for 70 percent and 30 percent of the total, respectively (USDA Forest Service 2007d). This small increase was mainly associated with an increase in logging employment not related to the Tongass National Forest (Figure 3.22-6). Employment decreased to 421 wood products jobs in 2006, with decreases in employment in all three active categories (Tongass logging, sawmill, and other logging) shown in Figure 3.22-6 (USDA Forest Service 2007d).

Employment decreases tend to lag behind decreases in production, and further declines in employment levels are possible even if there are no further changes in harvest levels.

Current Status of the Industry

It is clear from the preceding sections that the wood products industry in Southeast Alaska has undergone considerable change over the past decade. The closure of the Alaska Pulp Corporation (APC) pulp mill in Sitka and the KPC pulp mill in Ketchikan in 1993 and 1997, respectively, had a substantial effect on the overall regional demand for timber. Wood consumption by these pulp mills accounted for about half of Tongass National Forest timber harvest from 1970 through the early 1990s and chip by-products from the region's sawmills were historically used in pulp production (Brooks and Haynes 1997). The KPC pulp mill, for example, required 190 MMBF of pulpwood and/or chips to operate at its reported full annual capacity of 210,000 tons of pulp (USDA Forest Service 1997a). The analysis prepared for the 1997 Forest Plan Revision Final EIS noted that, on average, 19 percent of Native Corporation harvests were reportedly used in pulp production. The 1997 Forest Plan Revision Final EIS also noted that an average of 17 percent of Tongass National Forest logs were classified as utility grade, meaning that they were more likely to be used for pulp or chips because they could not be made into boards.

Figure 3.22-6
Southeast Alaska Timber Sector Direct Employment by Type, 1986-2006



Sources: USDA Forest Service 2002a, 2007d

Recent harvest data indicate the utility share of total annual harvests on the Tongass decreased from approximately 19 percent in 1996 to around 12 percent in 2004 and 9 percent in 2006 (USDA Forest Service 2002a, 2007d). Approximately 46.1 MMBF of utility and low grade saw logs were chipped in 2000 (26.9 and 19.2 MMBF, respectively). The majority of these chips were shipped to pulp mills in the continental U.S. (61.6 percent) and Canada (31.3 percent), with just 7.1 percent consumed in

Alaska. While these data indicate that a market existed for chips in 2000, the market is limited for low-grade log chips at this time (Brackley et al. 2006a).

Utility logs are logs that are at least two-thirds defective and, therefore, do not meet sawlog specifications. Since utility logs and sawlogs are mixed in the same tree stands, the loss of the market for wood chips has important implications for the economic viability of timber sales on the Tongass. (This is discussed further in the environmental consequences part of this section). As a result, timber sales on the Tongass include an Optional Removal clause (Forest Service Handbook [FSH]: 2409.22 Chapter 630) that allows sale purchasers to leave behind utility logs. These logs still have to be purchased as part of the timber sale but the purchaser no longer has to remove them, saving on logging and haul costs.

The Alaska Regional Forester (Region 10) signed a new policy in March 2007 that approved limited interstate shipments of unprocessed Sitka spruce and western hemlock (Bschor 2007). The policy allows shipment to the lower 48 states of unprocessed Sitka spruce and western hemlock sawlogs smaller than 15 inches in diameter at the small end of a 40-foot log, and grade 3 or 4 logs of any diameter. Shipments are limited on each sale to a maximum of 50 percent of total sawlog contract volume harvested of all species, including western redcedar and Alaska yellow-cedar, unless the Regional Forester grants an exception in advance based on case-specific unusual circumstances.

This policy, referred to as the Limited Interstate Shipment Policy, is expected to increase the utilization of timber harvested on the Tongass and improve the economics of timber sales by providing a market for smaller diameter and low grade material that cannot be processed profitably by sawmills in Southeast Alaska (Alexander et al. 2007).

A federal grant program was approved in 2001 and 2002 to help Alaska operators purchase drying and secondary processing equipment and mills in Alaska now have the ability to dry about 6.6 MMBF annually, with about 3.9 MMBF or 59 percent of the total State capacity located in Southeast Alaska. Approximately 0.8 MMBF of dry, surfaced lumber was produced in Alaska in 2004, with slightly more than half (51 percent or 412 thousand board feet [MBF]) of this total produced in Southeast Alaska (Nicholls et al. 2006). In addition, the Ketchikan Wood Technology Center (KWTC), a nonprofit research and product development center that operates in partnership with the USDA Forest Service and the University of Alaska, was established in 2000. The center's projects include development of new lumber grades and structural design values for Alaska wood species. Yellow cedar, hemlock, Sitka spruce and white spruce have been accepted as unique species for grading purposes by the American Lumber Standards Committee, with new design values for the species. In addition, KWTC implemented a testing program to develop new glued laminated timber beam designs utilizing Alaskan species and has been conducting other tests with potential future benefits to the industry in Southeast Alaska. The increased ability to produce dry, planed wood and updated grading rules for Alaskan lumber has allowed Alaskan producers to sell dimension lumber in local markets.

Market shifts partly reflect the movement of smaller operators away from exporting round logs, chips, or rough-cut green lumber toward value added products and a movement toward direct marketing of finished products. Value-added products produced by small mills on Prince of Wales Island, for example, include molding, tongue-and-groove, log cabin-style paneling, and shingles (Petersen and Bruns 2005), as well as wood for musical instruments.

Utilization of Mill Capacity

Changes in demand and prices have affected the Southeast Alaskan wood products industry and the profitability of the remaining facilities. The 1997 Forest Plan Revision

Final EIS reported an average utilization rate of 66 percent during the 1985 to 1994 time period (USDA Forest Service 1997a, Table 3-133). Utilization rates have shown a consistent downward trend in recent years, with mills in Southeast Alaska using just 12 percent (31 MMBF) of total active capacity in 2004 and 13 percent (32.1 MMBF) in 2005 (Table 3.22-5). Not only has the utilization rate decreased since the 1985 through 1994 time period, but the total active capacity that production is measured against has also declined, stabilizing at 250 MMBF since 2002 (Brackley et al. 2006a). Actual mill output has, however, been fairly consistent over the past five years: 39.7 MMBF in 2002, 32.0 MMBF in 2003, 31.0 MMBF in 2004, 34.7 MMBF in 2005, and 32.1 MMBF in 2006 (Brackley et al. 2006b; Juneau Economic Development Council 2006, 2007).

The results of the utilization studies summarized in Table 3.22-5 include the larger mills and operators in Southeast Alaska. There are also a number of smaller mills not included in the study. According to Petersen and Bruns (2005), for example, there are 16 small operations on Prince of Wales Island and only six of the facilities are included in Table 3.22-5. Although they are relatively small, these facilities may be important sources of economic activity for the communities they are located in or nearby.

[1] Only mills that were active in 2005 are included here. Two inactive mills were identified in the 2006 mill survey: KPC/Annette Island Hemlock Mill (70 MMBF) and Gateway Forest Products Veneer Mill (30 MMBF), and (15 MMBF). Five mills were identified in the 2006 survey as "out-of-business": Chilkoot Lumber Co., Gateway Forest Products Sawmill, Herring Bay Lumber Co., Kasaan Mountain Lumber & Log, and Metlakatla Forest Products. There are also a number of smaller mills not included in this study.
[2] Annual capacity is estimated based on the volume of material used during 500 eight-hour shifts.
[3] Actual mill production is the net sawlog volume (Scribner log scale) that was used during the year to manufacture sawn products.
[4] The Northern Star Cedar Products and Alaska Fiber facilities did not process timber in 2006. Northern Star was subdivided among three owners and Alaska Fiber sold its primary processing equipment, but reportedly has plans to purchase and install new equipment.

Market Demand

Demand can be thought of as the different amounts of a product buyers are willing to purchase at different prices. Demand is not a single number, but instead a series of price-quantity relationships. The same is true of supply. It is the combination of supply and demand that determines the quantity and price of goods produced and consumed. When we talk about "timber" on the Tongass we are talking about a spectrum of products that are not necessarily freely exchangeable or replaceable with one another or other sources of timber. Thus, timber includes a mix of species, each with a potentially different demand and price. Timber also includes a range of log types from high quality saw logs to utility logs for which demand and price differ markedly. Finally, the ability of timber to satisfy demand will differ according to the location of that timber relative to mills and other existing infrastructure. Under current market conditions, standing timber in the northernmost portions of the Tongass is unlikely to satisfy the demand for timber by mill operators in Ketchikan almost 500 miles away.

Accurately projecting future demand is difficult and cannot be considered an exact science. Market demand for Southeast Alaska timber and wood products depends upon numerous difficult to predict factors, including changes in technology, growth and exchange rates in key markets, changes in consumer tastes and preferences, as well as developments in other producing regions whose products compete with those of Alaska. While demand is difficult to predict, industry relies on a stable timber supply in order to conduct long-term business planning.

This section examines a number of indicators of demand for Tongass timber for the planning cycle, and discusses the methodologies, limitations, and conclusions of each. The analysis then considers the extent of the timber land base likely to be necessary to satisfy differing levels of demand.

Demand Indicators

Pacific Northwest Research Station Projections

The Forest Service has commissioned the Pacific Northwest Research Station to prepare a number of projections of demand for Tongass timber over time, including Brooks and Haynes 1990, 1994, 1997. In connection with ongoing monitoring and preparation of this EIS, the Forest Service commissioned the Pacific Northwest Research Station to prepare a new set of projections, resulting in Brackley et al. 2006a. Brackley et al. prepared a “derived demand” analysis and projected various demand figures for four potential scenarios using different assumptions about future markets and future processing facilities in Southeast Alaska. Derived demand looks at the overall end-market demand in foreign and domestic markets, and considers what portion of that demand Alaska is likely to fill. An example of end market demand in this case would be projected demand for Southeast Alaskan lumber (a final timber product) from markets in Asia.

Brackley et al.’s model is a trend-based projection of quantities. Trends in consumption (e.g., sawn wood in Japan) and trends in exports (e.g., pulp to all destinations) constitute the basic structure of the model. In preparing this analysis, Brackley et al. used information about U.S. exports to Japan, and Japanese import and consumption data, as a benchmark for the historic data since those exports represented, until recently at least, the majority of sawn-wood production from Southeast Alaska. They considered about 40 years of historic data and trends in manufactured wood products exports to Japan to project 20 years into the future and adjusted projections to address recent shifts and potential additional shifts towards the continental U.S. and other parts of the entire Pacific Rim (including North America), as an end-market for Alaska wood products. Additional information on the Brackley et al. analysis is provided in an addendum report that addresses questions and concerns raised with respect to the original analysis (Brackley and Haynes, in press).

Brackley et al.’s analysis has a number of limitations. Because it is based on trends over a long historic period, it has “smoothed out” short-term fluctuations. The timber industry is currently in a period of transition, increasing the likelihood of volatile shifts. In addition, demand cannot be considered in a vacuum. Demand will be influenced by costs of production, which in turn will be influenced by the willingness of producers to invest in improvements to efficiency. Decisions made in the Forest Plan relating to the timber base are believed likely to also have an impact on the producers willingness to invest.

Although Brackley et al. (2006a) described the following four scenarios, those are not necessarily the only possible scenarios, and considerable variation is possible within any of the scenarios. Each scenario described below assumes the foundation of the preceeding scenario. In other words, Scenario 2, for example, describes an increase in demand beyond Scenario 1 and so forth.

Scenario 1, Limited Timber Production, was an approximation of the current status of the timber industry in Southeast Alaska in 2006 with no market for lower grade logs. The recent policy change (March 2007) that resulted in the Limited Interstate Shipment Policy is expected to change this situation, with timber sale purchasers now able to export lower grade logs to the continental U.S. The current status is believed to be largely the result of supply limitations and not necessarily related to market demand.

Scenario 2, Expanded Timber Production, assumes an increase in the Alaska share of the Pacific Rim markets, but no creation of facilities to process lower grade logs. However, a veneer plant could be a portion of the demand stimulation assumed in Scenario 2, as could the Limited Interstate Shipment Policy.

Scenario 3, Medium Integrated Industry, assumes a demand stimulation in 2008 that creates demand for lower grade logs. Potential forms of demand stimulus identified by Brackley et al. (2006a) included medium density fiberboard (MDF) plants or biomass facilities. The Limited Interstate Shipment Policy could also contribute to this demand stimulus.

Scenario 4, High Integrated Industry, assumes the demand stimulus in Scenario 3 plus an additional stimulus, such as another facility coming on line in 2012.

Scenarios 3 and 4 also assume a form of demand stimulation, such as a veneer plant, that uses medium and low-grade logs. Based on these scenarios, Brackley et al. developed the projections shown in Table 3.22-6. Brackley et al.'s projected volumes for the first two scenarios include decked sawlogs at the sawmills plus a portion of cedar logs that would be exported. They do not reflect the total amount of timber that needs to be sold to produce these decked sawlog timber and cedar volumes.

Table 3.22-6
Timber Production 1983 to 2002 and Demand Projections for 2003 to 2025 (MMBF)

	Brackley et al. Scenarios			
Period[1]	**Limited Lumber Production**	**Expanded Lumber Production**	**Medium Integrated Industry[2]**	**High Integrated Industry[2]**
1983-1987	281.0	281.0	281.0	281.0
1988-1992	414.0	414.0	414.0	414.0
1993-1997	200.2	200.2	200.2	200.2
1998-2002	93.3	93.3	93.3	93.3
2003-2007	**30.0**	**33.7**	**44.4**	**44.4**
2008-2012	**34.7**	**52.0**	**169.0**	**185.8**
2013-2017	**38.7**	**75.4**	**204.4**	**299.0**
2018-2022	**43.0**	**108.1**	**204.0**	**317.0**
2022-2025	**46.7**	**142.9**	**204.4**	**360.1**

[1] The projections are for 2003 through 2025 and shown in bold in this table. The data for 1983 through 2002 are the actual volumes processed in the years shown.
[2] These projections assume an industry (one or more facilities) will be created that uses pulp chips produced by Southeast Alaska sawmills, low grade logs, and other biomass products in fiber based board, chemical, or energy facilities. Medium density fiberboard is one possible alternative identified in Brackley et al. (2006a). Chemical and energy uses are also possible.
Source: Brackley et al. 2006a, Table 3

Annual projections are presented for all four scenarios in Table 3.22-7. In addition to Brackley et al.'s estimated volume projections, this table also includes the total timber sale volume that would be needed under Scenarios 1 and 2. The total sale volumes for 2022 for each scenario are used in the long-term effects analysis in the Environmental Consequences part of this section.

Installed Capacity and the McDowell Group et al. (2004) Southeast Conference Projections

Another way to consider the potential volumes that might be demanded by the timber industry in Southeast Alaska is to look at installed mill capacity and determine how much timber must be sold and harvested to run the mills at various rates of mill capacity utilization. While we can assume mill owners want to operate their mills at an efficient level if economic timber supply is available, a limitation to this type of analysis is that it assumes there is a purchaser willing to buy the product at a price equal to or greater than the cost of production. In the long run, a mill owner cannot be expected to operate a mill at an "efficient" rate if the mill owner cannot sell the product at a profit. It should also be noted that a mill may not be able to operate indefinitely at a utilization rate far below the economically efficient rate without risking bankruptcy.

Table 3.22-7
Projected Demand for National Forest Timber from Brackley et al. (MMBF)

	Limited Lumber Production		Expanded Lumber Production		Medium Integrated Industry	High Integrated Industry
Year	Estimated Volume[1]	Total Sale Volume[2]	Estimated Volume[1]	Total Sale Volume[2]	Estimated Volume[1]	Estimated Volume[1]
2005	31	47	35	53	45	45
2006	32	48	38	57	55	55
2007	33	50	41	62	67	67
2008	33	50	44	66	139	139
2009	34	51	48	72	151	151
2010	35	53	52	78	166	166
2011	35	53	56	85	184	184
2012	36	54	60	91	204	286
2013	37	56	65	98	204	291
2014	38	57	70	106	204	295
2015	39	59	75	113	204	299
2016	39	59	81	122	204	303
2017	40	60	87	131	204	308
2018	41	62	93	140	204	312
2019	42	63	100	151	204	317
2020	43	65	108	163	204	325
2021	44	66	116	175	204	333
2022	45	68	124	187	204	342
2023	46	69	133	201	204	351
2024	47	71	143	216	204	360
2025	48	72	153	231	204	370

[1] The projections for Scenarios 1 and 2 include sawlogs, cedar export, and chip volumes available from sawmill production. They do not include low grade material or utility logs. Scenarios 3 and 4 include sawlogs, cedar exports, chip volumes, low-grade material, and utility.
[2] The total sale volume projections represent the total harvest that would be necessary to produce the estimated volume under the first two scenarios. These total volumes include the low quality material (low grade material or utility logs) not included in the demand projections. These figures assume that the initial estimated volume would comprise 66 percent of the total required harvest.
[3] The data presented in this table were used to calculate the 4-year averages summarized in Table 3.22-6. The effects analysis uses the projected demand numbers for 2022 to compare scenarios and alternatives.
Source: Appendix G, Table 2

An analysis prepared for the Southeast Conference—"Timber Markets Update and Analysis of an Integrated Southeast Alaska Forest Products Industry" (McDowell Group et al. 2004)—considered installed capacity of Southeast mills, projected a harvest volume that would allow the mills to operate at an efficient level assuming the existence of an integrated industry, and concluded that a minimum of 200 MMBF total harvest would be required.[1] However, they concluded that the most efficient use of timber from the Tongass National Forest would most likely include other added-value manufacturing, such as a veneer mill. The industry would be most efficient with at least two of each type of manufacturing facility to foster competitive bidding for materials and labor. Depending upon the types of facilities, this could require an annual harvest of 350 MMBF or more from the Tongass (McDowell Group et al. 2004; McDowell Group 2006b).

Recent Sales and Harvest Figures

Another possible way to assess timber demand is to consider sale and harvest figures in recent years. Table 3.22-8 shows annual timber sale harvest since 1994.

Use of recent harvest figures as an indicator of demand has several limitations. Since 1997, much of the timber prepared for sale has been subject to appeal and litigation activities that have postponed our ability to offer the material. In recent years, Congressional Appropriation Act provisions have prohibited the Tongass National Forest from offering timber sales that do not appraise positively using the residual-value appraisal method. Many timber sales have not appraised positively and others have been delayed through litigation; it is unclear what the actual harvest levels would have been if these constrictions on supply were not present.

Table 3.22-8
Tongass National Forest ASQ compared to Actual Harvest, 1994 to 2006 (MMBF)

Fiscal Year[1]	ASQ	Actual Harvest
1994 (End of APC contract)[2]	549	276
1995[2]	549	221
1996[2]	549	120
1997 (End of KPC contract)[2]	549	107
1998	267	120
1999	267/187[3]	146
2000 (Last KPC harvest)	187[3]	147
2001	187/267[3]	48
2002	267	34
2003	267	51
2004	267	46
2005	267	50
2006	267	43

[1] Fiscal Year: October 1 to September 30 the following year.
[2] The Allowable Sale Quantity (ASQ) for 1994 through 1997 included 450 MMBF net sawlog volume and 549 MMBF total harvest.
[3] In May 1997, the Tongass Plan was revised, with a resulting allowable sale quantity of 267 MMBF. In April 1999, a new Record of Decision was issued with a resulting allowable sale quantity of 187 MMBF. In March 2001, the 1999 ROD was vacated by the US District Court, District of Alaska and the allowable sale quantity reverted back to 267 MMBF.

[1] Southeast Conference is a regional, nonprofit corporation and the State-designated Alaska Regional Development Organization, the federally designated Economic Development District, and the federally designated Resource Conservation and Development Council for Southeast Alaska (see http://www.seconference.org/index.html).

The Tongass Forest Plan assigns Land Use Designations (LUDs) to various portions of the Forest and designates the types of activities allowable within those LUDs. Suitable land in LUDs where timber management can be considered constitutes the “timber land base” of the Forest. As part of the Forest Plan development process, the Forest Service calculates the average decadal volume that could be produced from that timber base over the rotation period, observing all of the legal requirements and standards and guidelines associated with the Plan. The figure resulting from that calculation is the Allowable Sale Quantity (ASQ). The ASQ should not be equated with the ability of the Forest Service to satisfy timber demand alone. Additional volume, for example, can be produced from wildlife habitat enhancement thinning in young-growth forest in the beach fringe and old-growth reserves. Production of this type of additional volume may be appropriate to meet objectives other than timber production provided no irreversible damage would occur and restocking was assured.

Conversely, not all suitable land is likely to be harvested. Some lands within the suitable base may not be economically feasible to harvest for example. The Forest Plan distinguishes between two types (components) of lands within the suitable base as a function of logging system implications. The two non-interchangeable components (NICs) are referred to as NIC I and NIC II lands. NIC I includes lands that can be harvested with normal logging systems; NIC II, is comprised of lands with especially high logging costs usually due to isolation or special harvesting equipment requirements. Although NIC I timber does not exhibit the problems of NIC II timber, not all NIC I timber, is necessarily economic. The proportion of NIC I lands that would render economic timber sales could increase as the timber industry becomes more integrated. In the absence of a facility that utilizes utility and lower grade logs, a timber sale must be sustained solely on the profits made from the higher grade sawlogs, even though the operator must harvest and pay for the lower grade logs.

The Limited Interstate Shipment Policy increases the likelihood that timber sales in parts of the Tongass National Forest will have a positive appraisal under current market conditions. The policy is also expected to increase the utilization of timber harvested on the Tongass, by increasing the amount of material that can be economically removed from the woods, and concurrently decreasing the amount of material that formerly had to be chipped, stored, or disposed of by the mills (Alexander et al. 2007).

Logistics in Southeast Alaska also influence where and when timber is economic to harvest. Currently the timber base is spread throughout the entire Tongass National Forest, while most of the saw mills are located in the southern portions of the Forest. The high cost of access and transportation between the timber supply and processing mills reduces the likelihood of meeting the needs of mill owners where distances are great.

The ASQ reflects the maximum allowable level of timber harvest under each alternative and assumes every acre modeled and scheduled for timber harvest will actually be harvested. The preceding paragraphs describe the considerations and constraints that make it unlikely that every acre will be scheduled for harvest.

Juneau Economic Development Council and a Subcommittee of the Tongass Futures Roundtable

These groups have made estimates of the minimum timber volume required for the efficient operation of various processing facilities, as discussed later in the effects section and shown in Tables 3.22-17 and 3.22-18. The estimated minimum volume for efficient sawmill operation is approximately 66 percent of existing mill capacity (138 MMBF) based on the four largest existing sawmills in Southeast Alaska, with some allowance for smaller mills (see Table 3.22-17). The minimum estimated volume necessary to supply a veneer plant is 30 MMBF of mid-value logs, with 80 to 100 MMBF of No. 3 sawlogs and utility logs required to support an MDF or Bioenergy facility. Using these estimates a total of 248 MMBF to 268 MMBF is the minimum volume necessary to support an integrated industry. The limitations of this analysis are similar to those in the installed capacity discussion above, in that there must be an end purchaser willing to buy the product at a price equal to or greater than the cost of production.

Relationship between Demand over the Planning Cycle and Annual Demand

Section 705 (a) of the Tongass Timber Reform Act of 1990 states:

Subject to appropriations, other applicable law, and the requirements of the National Forest Management Act of 1976 (Public Law 94-558), except as provided in subsection (d) of this section, the Secretary shall, to the extent consistent with providing for the multiple use and sustained yield of all renewable forest resources, seek to provide a supply of timber from the Tongass National Forest which (1) meets the annual market demand for timber from such forest and (2) meets the market demand from such forest for each planning cycle.

The Tongass Timber Reform Act (TTRA) speaks of annual market demand and demand over each planning cycle (10 to 15 years into the future and beyond). The Forest Plan itself does not authorize any timber harvest. Such harvest is authorized by site-specific timber sale projects, which implement the plan. Thus, it could be said that the Plan itself does not directly meet demand for timber. Rather the Plan sets the conditions under which the Forest Service can seek to meet market demand through the cumulative sales of the annual timber sale program over the planning cycle.

The Forest Service seeks to meet market demand for Tongass timber on an annual basis by establishing annual timber sale objectives using a methodology developed by Morse (2000). This methodology uses a number of inputs including the Pacific Northwest Research Station projections, installed mill capacity, utilization rates, and market trends to determine annual sale offer levels (supply) (see Appendix G, Timber Demand). The goal of the Forest Service is to have a 3-year supply (approximately) of timber under contract to meet sale objectives. The 3-year supply approach recognizes timber cannot be harvested instantaneously and that purchasers must have some flexibility to respond to market changes. Once the 3-year level is reached, the agency builds shelf volume (sale projects with completed NEPA and field work – ready for offer) and sells additional timber as existing inventories are harvested. In this way, the agency seeks to enable the industry to respond to short term changes in markets. The ratio of contract volume to harvest peaked in 2002, at 6.8, but dropped closer to the 3-year supply objective in 2003. In 2004 and 2005 the ratio dropped to 1.7. Recent ratios of volume under contract to harvest are potentially misleading. Harvests have declined considerably over the past few years, resulting in increasing contract volume to harvest ratios through 2002 in spite of declining contract volumes. Some of the volume under contract in 2002 and 2003 was in sales cancelled in 2004 and 2005.

In 2004, Section 339 of the Department of the Interior and Related Agencies Appropriations Act for fiscal year (FY) 2004, Public Law No. 108-108, provided that the Secretary of Agriculture may cancel, with the consent of the timber purchaser, a number of timber sale contracts on the Tongass National Forest awarded between October 1 1995 and January 1 2002. A given sale could be cancelled provided that the Secretary determined, at the Secretary's sole discretion, that the sale would result in a financial loss to the purchaser, and the costs to the government of seeking a legal remedy against the purchaser would likely exceed the cost of terminating the contract. By the end of FY 2005, a total of seventeen sales (with approximately 122 MMBF) on the Tongass National Forest were cancelled. It is the intent of the Tongass National Forest to reconfigure cancelled timber sales and re-offer that portion of the volume that is economically viable.

Projecting demand over the planning cycle has a higher degree of uncertainty and depends on numerous factors that are difficult to predict, including changes in technology, growth and exchange rates in key markets, changes in consumer tastes and preferences, as well as developments in other producing regions whose products compete with those of Alaska. The difficulty in developing long-term projections for the timber industry in Southeast Alaska is further exacerbated by the current circumstances confronting the industry, which, as discussed in the preceding sections, has been in a period of transition since closure of the pulp mills in the 1990s. With this in mind, recent studies (Brackley et al. 2006a; McDowell Group et al. 2004;

McDowell Group 2006b) have considered the demand for timber based on a number of different scenarios that assume different futures for the timber industry. The identified future scenarios range from a projected longer-term demand of 47 MMBF through 360 MMBF. Based on these studies, the Forest Service identified an upper planning cycle demand of 360 MMBF.

Recreation and Tourism

The following section is divided into two subsections or parts. The first part discusses trends in recreation and tourism and related employment for Southeast Alaska as a whole. This discussion draws upon region-wide visitor numbers and related employment estimates to the extent they are available. The second part discusses the same issues with specific reference to the Tongass National Forest. Trends in visitation to Southeast Alaska and the Tongass National Forest are discussed in detail in the *Recreation and Tourism* section of this document and, as a result, are only briefly summarized in the following subsections.

Recreation and Tourism in Southeast Alaska

Trends in Visitation

The number of visitors to Southeast Alaska has grown substantially since the early 1990s. Summer visitors to Southeast Alaska more than doubled between 1993 and 2006, increasing from 502,800 in 1993 to 1,160,000 in 2006, an increase of 131 percent (McDowell Group et al. 2007). Statewide, the total number of visitors increased by 40 percent over the same period. The relatively large increase in visitation to Southeast Alaska reflects the dramatic growth in the number of cruise ship passengers visiting the region. The number of cruise ship passengers visiting Juneau, for example, more than tripled between 1993 and 2006, increasing from approximately 306,600 in 1993 to 953,000 in 2006 (Table 3.15-13 in the *Recreation and Tourism* section; Juneau Convention and Visitors Bureau 2007). The number of passengers docking at Juneau is considered representative of the total number of cruise ship passengers because most cruise ships visiting Southeast Alaska stop there.

Anecdotal evidence suggests that the number of independent visitors (i.e., non-cruise ship visitors) remained relatively constant from 1980 through 2002. Recent estimates by the Juneau Convention and Visitors Bureau suggest, for example, that the number of independent visitors to Juneau has held relatively constant at around 100,000 (Schroeder et al. 2005) over this same period. Data for Southeast Alaska as a whole indicate cruise ship visitors increased from about 64 percent of total visitors to the region in 1985 to 75 percent of the total in 2001. About 90 percent of visitors to Juneau in 2003 were estimated to be cruise ship passengers (Schroeder et al. 2005).

Employment and Contribution to the Regional Economy

Recreation and tourism-related employment is difficult to accurately quantify because visitors spend their money throughout the local economy. There is no single “tourism industry” and no direct measures of tourist-related income or employment. Components of travel and tourism activities are instead partially captured in other economic sectors, such as retail trade (e.g., grocery stores and gift shops), transportation, hotels and other lodging places, and amusement and recreation services.

There are no readily available current estimates of total recreation and tourism-related employment for Southeast Alaska. The most recent study that provided data by Alaska region (McDowell Group 1999) estimated that recreation and tourism (or in their terms vacation/pleasure visitors) supported approximately 4,154 direct jobs in Southeast Alaska in 1998, approximately 22 percent of Alaska’s total recreation and tourism-related employment. The Draft and Final SEIS used the basic approach employed in the McDowell analysis and estimated that recreation and tourism supported 4,185 and 4,278 direct jobs in Southeast Alaska in 1999 and 2001, respectively (USDA Forest Service 2002b, 2003b). Based on these estimates, recreation and tourism accounted for 7 percent and 8 percent of total employment in Southeast Alaska in 1999 and 2001, respectively. Unfortunately it is not possible to update these estimates because the baseline employment data compiled by the Alaska DOL are no longer available in the same format following the national shift from the Standard Industrial Classification (SIC) system to the North American Industrial Classification System (NAICS).

In the absence of a reliable current estimate of recreation and tourism-related employment for Southeast Alaska, employment in the leisure and hospitality sector is used as a proxy for recreation and tourism employment in 2005. Employment in this sector accounted for approximately 9 percent of total employment in Southeast Alaska in 2005 (see Table 3.22-3 for details).

While there are no current estimates of total recreation and tourism-related employment for Southeast Alaska, two studies offer some insight into the economic contribution that recreation and tourism makes to the regional economy. The first study was a survey of commercial recreation businesses that use the public lands and waters of Southeast Alaska. Conducted in 2000, this survey found that cruise ship passengers accounted for 41 percent of total clients, ranging from 22 percent of clients for businesses with fewer than 200 clients a year to 91 percent of clients for businesses with more than 10,000 clients a year (Alaska Division of Community and Business Development [DCBD] 2001). This survey also found that 86 percent of outfitter/guide businesses had annual revenues of less than $100,000 in 1999. Six firms reported revenues over $1 million, including one firm with revenues exceeding $10 million. A similar distribution is evident in terms of clients served, with the majority of firms serving less than 100 clients, a smaller number of firms serving considerably larger numbers, and one firm serving more than 100,000 clients in 1999.

Given the rapid growth in the number of cruise ship passengers visiting the region since 2000, it seems reasonable to assume that the number of clients seeking guided recreation opportunities and the number of outfitter/guides operating in the region has grown. Outfitter/guide data for the Tongass, for example, indicate a 22 percent increase from 2004 to 2005 in the number of clients served by outfitter/guides Forest-wide (see Table 3.15-18 in the *Recreation and Tourism* section).

A second study that provides important insight into the contribution of nature-based tourism to the regional economy was prepared by the Institute of Social and Economic Research at the University of Alaska Anchorage and involved field research conducted in the summers of 2005 and 2006 (Dugan et al. 2006). This study focused on a limited number of communities and sought to provide insight into revenues generated, the types of activities attracting tourists, and the flows of money through the economy. The findings of the study indicate that nature-based tourism generates substantial revenues in the region, with an estimated $250 million generated in annual direct business revenues for the companies surveyed in Sitka, Juneau, and Chichagof Island (Dugan et al. 2006). The study also found that nature-based tourism takes a number of different forms and the ratio of cruise ship passengers to independent travelers varies by location. Most nature-based activities that originate in Ketchikan, for example, fell into four general categories: flightseeing, marine charters, adventure experiences, and general sightseeing. In all cases, the majority of clients participating in these activities were cruise ship passengers. Nature-based tourism on Chichagof Island, on the other hand, included a mix of cruise ship passengers and independent travelers, depending on the location and activity involved (Dugan et al. 2006).

Recreation and Tourism on the Tongass National Forest

The following discussion focuses on existing and projected recreation use levels and related employment. The existing supply of recreation opportunities, which forms an important part of the recreation analysis presented in the environmental consequences part of this section, is discussed with respect to Recreation Opportunity Spectrum (ROS) settings and inventoried Recreation Places in the *Recreation and Tourism* section of this document.

Forest Use and Visitation

The preceding discussion indicates that there has been a substantial growth in the number of visitors to Southeast Alaska over the past decade or so.

While it is reasonable to assume that the vast majority of visitor recreation and tourism activity in the region is related to the natural environment, not all of the activity generating this employment can be directly linked to the Tongass National Forest. Many visitors experience the Tongass passively, from the deck of a cruise ship, for example, without directly using the Forest for recreation purposes. In addition, while the Tongass includes approximately 80 percent of the land area in Southeast Alaska, there are other lands that offer wildland recreation opportunities in the region, including the 3.3 million acres of National Park Service lands and recreation lands managed by the State of Alaska. Further, other popular recreation and tourism activities, such as saltwater fishing, sea kayaking, and shopping, do not take place on the Tongass.

It should, however, be noted that cruise ship companies have heavily marketed Forest-related activities in recent years and many passengers do take at least one trip to the Forest during their visit. Icefield helicopter tours and visits to the Mendenhall Glacier by cruise ship passengers have, for example, increased substantially (see Table 3.15-15 in the *Recreation and Tourism* section). Recent survey data (2005) indicate approximately 83 percent of cruise visitors to Juneau participated in at least one tour while in port. Glacier tours were the most popular type of tour in 2005, with 42 percent of cruise visitors taking this type of tour. Wildlife/marine life viewing, the Mt. Roberts Tramway, and flightseeing via helicopter were also popular (McDowell Group 2005).

With these caveats in mind it is apparent that not all of the recreation and tourism employment and economic activity in Southeast Alaska can be directly attributed to the Tongass. In addition, visitors to the region comprise only part of total recreation use on the Tongass. Residents of local communities also make extensive use of the Forest for recreation purposes.

The question of recreation use is complicated because only limited forest visitation data are presently available. There are currently two main sources of data: the results of the first Alaska National Visitor Use Monitoring (NVUM) program, which were published in 2004, and data that were collected for specific recreation places in the 1980s and early 1990s.

The final results of the first Alaska NVUM program, which involved surveys conducted over 3 years, were published in August 2004 (Kocis et al. 2004). According to the NVUM analysis there were an estimated 1.83 million national forest visits and 2.13 million site visits to the Tongass in 2003 (Kocis et al. 2004). NVUM has standardized definitions of visitor use measurement to ensure that all national forest visitor measurements are comparable. A national forest visit, as defined by the NVUM, is the entry of one person onto the Forest to participate in recreation activities for an unspecified period of time and may include multiple site visits. A site visit, as defined by the NVUM study, is the entry of one person onto a national forest site or area to participate in recreation activities for an unspecified period of time.

Prior to the NVUM program, Forest-wide recreation use statistics were last compiled for the Tongass National Forest in 1995. The basic measurement of recreational activity was the Recreation Visitor Day (RVD), which is usually obtained through the counting of use permits, visitor surveys, or observation. An RVD is 12 hours of recreation use by one individual. The measures used in the NVUM program are not directly comparable with these estimates. In addition, the NVUM estimates were developed for the entire forest, while the data collection efforts in the 1980s and early 1990s focused on identified and specific recreation places (see the *Recreation and Tourism* section of this document).

While the NVUM data are more recent, it is not possible to extrapolate future use from just one year of data, even though all indications suggest that recreation use in the region and on the Tongass has been increasing in recent years. In the absence of more recent detailed information, the following analysis uses RVD data compiled for identified recreation places from 1984 through 1995 to assess existing and future conditions. These data may not accurately reflect current levels of use on the Tongass, but they are sufficient to allow a comparison of alternatives. This comparison is based on the projected effects of the alternatives on recreation supply (in the form of ROS settings). Demand is assumed to be consistent across all the alternatives and the exact number is less important in this analysis than the overall trend.

Existing and Projected Use (RVDs)

RVD data are presented for three groups based on the Recreation Opportunity Spectrum (ROS) system.

ROS 1:
Primitive
Semi-Primitive Non-Motorized
ROS 2:
Semi-Primitive Motorized
ROS 3:
Roaded Natural, Roaded Modified, Rural and Urban

The RVD data compiled for 1984 through 1995 are divided into three groups based on the ROS system that is used to inventory and classify different recreation settings on the Forest (see Table 3.15-2 in the *Recreation and Tourism* section). These three groups consist of Primitive and Semi-Primitive Non-Motorized settings (here termed ROS 1); Semi-Primitive Motorized settings (ROS 2); and Roaded Natural, Roaded Modified, Rural, and Urban settings (ROS 3) (see Table 3.15-2). Semi-Primitive Motorized settings (here termed ROS 2) accounted for a majority of recreation use on the Tongass in 1994, with 62 percent of recorded RVDs occurring in ROS 2 settings. ROS 1 settings, as defined here, accounted for 20 percent of the use, with the remaining 18 percent of RVDs taking place in ROS 3 settings.

Historic and projected recreation use is presented in Figure 3.22-7. Future use projections are based on actual use estimates from 1984 to 1995, with a trend line (based on these data) used to project future levels of demand. Annual estimated use is presented by ROS class for 1984 through 1995 and for 2000, 2005, and 2010 in Table 3.22-9. Total RVDs are divided into ROS classes based on the shares identified for 1994, which are assumed to remain constant throughout this analysis. These shares are presented graphically in Figure 3.22-8, which also identifies the projected supply of these settings based on the Forest-wide Geographic Information System (GIS) database that was updated for this analysis (see the *Recreation and Tourism* section of this document).

A comparison of projected demand with supply by ROS class and recreation place indicates that ROS 2 (Semi-Primitive Motorized) is the only class in which demand is expected to exceed supply over the next decade.

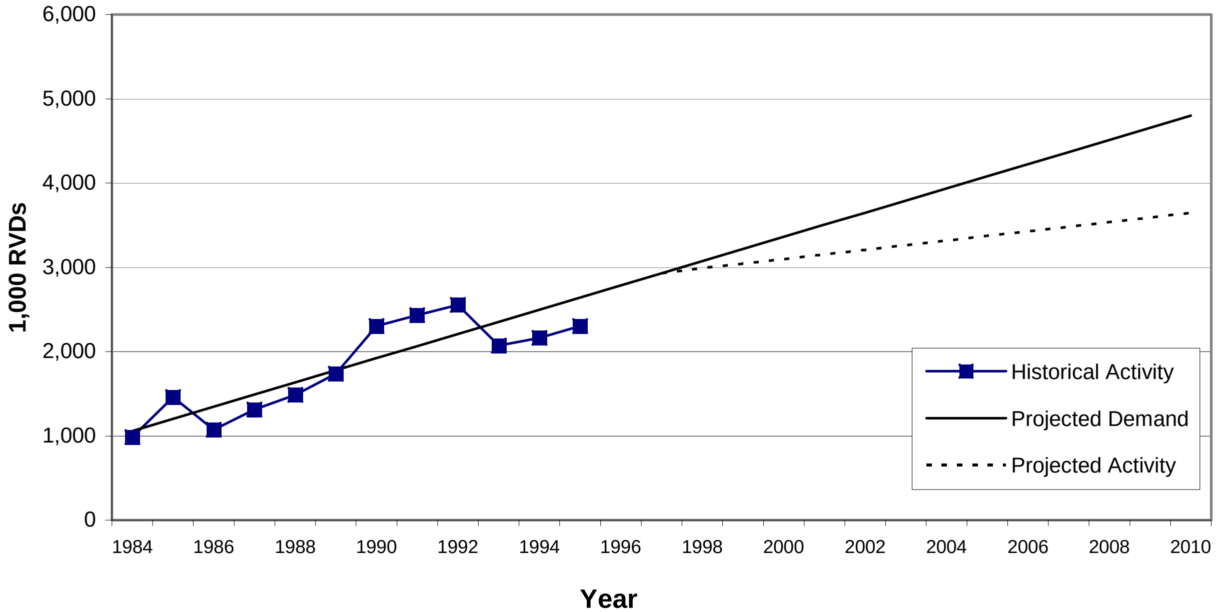
Although outfitter/guides charge clients for services that involve the Tongass National Forest, recreational use on public lands is not typically a market good. In other words, the Forest Service does not typically charge individuals to use the Forest for recreation. As a result, where supply is binding, use restrictions rather than price increases are the most likely result. This analysis assumes that RVD use within a certain ROS class will not exceed supply within that class (for this analysis, supply is equated to the current level available; alternative supply levels are evaluated in the Effects Analysis). ROS 2 is the only class in which demand exceeds supply over the next decade, with the projected number of RVDs having exceeded estimated supply in 1998. In this case, demand is assumed to be constrained by the available supply. The second part of Table 3.22-9 and the dashed line shown in Figure 3.22-7 show the effect that constraining ROS 2 in this manner would have upon projected use. This modified projection, which serves as the baseline for the effects analysis, assumes that recreation use in ROS 1 and ROS 3 settings would not be substituted for the projected unmet ROS 2 demand.

The supply of ROS settings used in this analysis is limited to specifically identified recreation places, with demand also assumed to occur in these places. There are an estimated 870,000 ROS 2 acres in identified recreation places compared to approximately 1.5 million ROS 2 acres Forest-wide (see Tables 3.15-3 and 3.15-5 in the *Recreation and Tourism* section of this document). The recreation economic analysis assumes that demand would continue to focus on ROS 2 areas in recreation places and, therefore, exceed supply in these areas. Viewed on a Forest-wide basis, ROS 2 demand would not exceed Forest-wide supply until sometime after 2010.

This approach recognizes that recreation use is not evenly distributed on the Forest, with some areas, identified here as inventoried Recreation Places, receiving much higher levels of use than others. High levels of recreation activity generally take place during the summer and correspond with cruise ship activity, increased private boating by both residents and non-residents, and a general increase in resident recreation activity. High use levels and/or limited capacity have resulted in reports of use exceeding capacity in certain areas, which generally correspond with the ROS 2 areas evaluated here. The Shoreline Outfitter/Guide EIS prepared for the north portion of the Forest, for example, identified 15 "hotspots" where there was a perception of crowding (USDA Forest Service 2002c). These areas mainly involved popular saltwater bays adjacent to the Forest and included Eliza Harbor, Gambier Bay, Greens Creek, Brothers Islands, George Island, Idaho Inlet, Mud Bay, Pinta Cove, Point Adolphus, Mallard Bay, Williams Cove, Slocum Inlet, Kelp Bay, Lake Eva Trail, and Patterson Bay. Perceptions of and actual crowding exist at other locations on the Forest, including the Anan Creek Wildlife Viewing Area and Margaret Bay near Ketchikan.

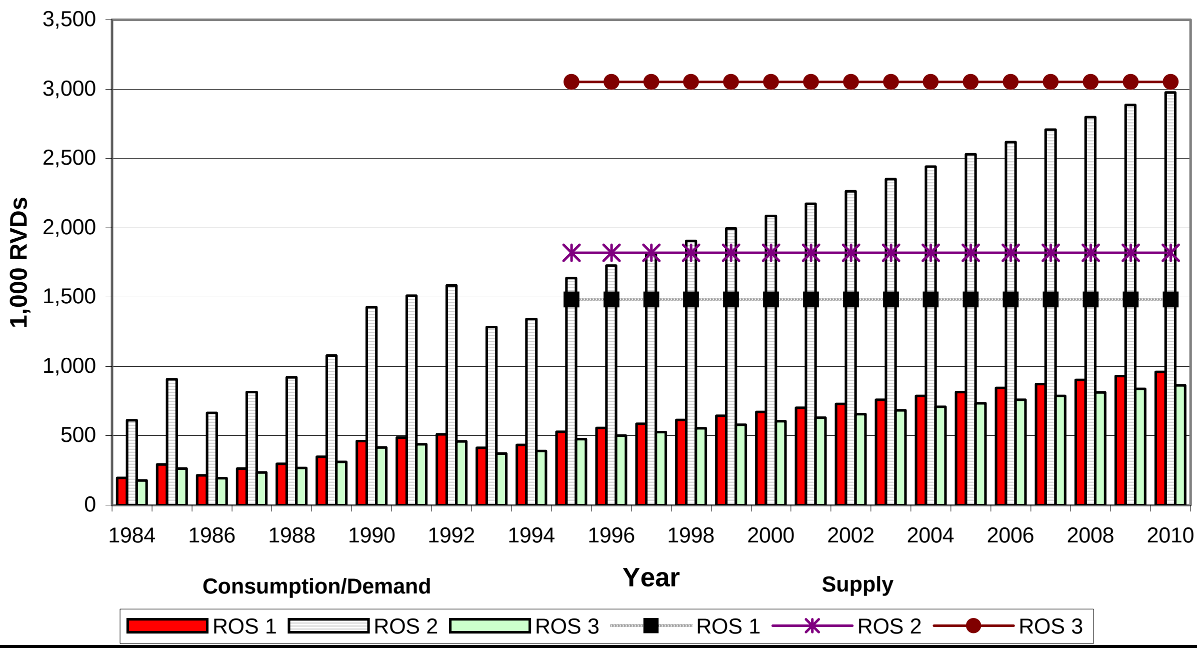
The following analysis also assumes that there would be no change in the current availability of recreational settings. This is not necessarily the case for identified recreation places or the Forest as a whole. Shoreline areas or other areas accessible by floatplane or helicopter that are presently allocated to Primitive or Semi-Primitive Non-Motorized settings (ROS 1) could be reallocated to the Semi-Primitive Motorized setting (ROS 2) in the future if patterns of use or other factors change. While these assumptions represent a simplification of underlying realities, they are necessary to produce a quantified estimate of the relation between recreation supply and demand and allow a comparison of alternatives.

Figure 3.22-7
Historical and Projected Recreational Activity on the Tongass National Forest in RVDs



Note: The dashed line represents future recreational activity constrained by the supply of ROS 2 settings.
Source: USDA Forest Service 1997a (Figure 3-23; updated using 2006 ROS supply data).

Figure 3.22-8
Historical Consumption, Projected Demand, and 2006 Supply for Recreation Activity on the Tongass National Forest by ROS Group



Employment and Earnings

The direct employment estimates presented in Table 3.22-9 are based on a job/RVD ratio of 0.00074. This ratio was developed for the 1997 Forest Plan EIS analysis based on visitor survey data and data from a regional economic model (IMPLAN) (USDA Forest Service 1997a, p. 3-460). This approach assumes that the average amount of employment generated by a single RVD is constant over time and that this number is the same for both Tongass-related recreation and the region as a whole, as well as for different types of recreation on the Tongass. While these assumptions may not accurately reflect underlying realities, they are necessary to produce a quantified estimate of the relation between recreation activity and employment.

Nonresidents were assumed to account for 44 percent of historic and projected RVDs and a commensurate share of employment for the purposes of this analysis. Total employment (direct, indirect, and induced) generated by nonresidents is presented in the last row of Table 3.22-9, entitled "Total from Nonresident." A reduction in out-of-state recreational activity due to decreased recreational opportunities (ROS settings) is assumed to result in a net economic loss to the region. Local residents, on the other hand, are assumed to spend their money elsewhere in Southeast Alaska, and no net loss in economic activity is incurred. This is not to say that this type of effect would be neutral if it were to occur. This is discussed further in the Environmental Consequences section.

Table 3.22-9
Tongass-Related Recreation and Tourism: Historic and Predicted Consumption in Recreation Visitor Days (RVDs)

From Nonresident[5]	321	476	349	428	484	566	750	793	832	674	705	860	1,008	1,097	1,186
Total from Nonresident[6]	**389**	**576**	**423**	**518**	**586**	**685**	**907**	**959**	**1,006**	**816**	**853**	**1,041**	**1,220**	**1,327**	**1,435**

[1] Figures for 1984 to 1995 are estimated from historical use data. Figures in subsequent years are estimates based on a linear projection using the 1984 to 1995 estimates of actual use (see Figure 3.22-7). The distribution of RVDs by ROS setting is based on estimates for 1994 ROS classes 1, 2, and 3 are assumed to account for 20 percent, 62 percent, and 18 percent of total RVDs, respectively.

[2] Estimated available recreation opportunities are based on the supply of ROS settings in identified recreation places on the Tongass. These estimates are for National Forest System (NFS) lands only. They do not include State or private lands in recreation places within the Tongass National Forest boundary.

[3] Projected consumption of RVDs by ROS class is based on projected demand with the consumption of ROS 2 opportunities constrained by the existing supply.

[4] Direct employment is calculated using a job/RVD ratio of 0.00074. This ratio was developed for the 1997 Forest Plan Revision Final EIS analysis (see USDA Forest Service 1997a, p. 3-460).

[5] Nonresident use is estimated to be 44 percent of total forest use. This analysis focuses upon nonresident visitors because jobs generated by nonresident expenditures on goods and services are considered comparable to an export industry that brings new money into the region, creating new wealth and development opportunities. Resident recreational activity, on the other hand, brings no new money into the region, and thereby does not expand the local job base.

[6] Total employment generated by nonresident activities is estimated using a multiplier of 1.21.

Source: USDA Forest Service 1997a (Table 3-136)

Commercial Fishing and Seafood Processing

While commercial salmon fishing represents the largest share of Southeast Alaska's fishing industry (42 percent based on ex-vessel value in 2005), halibut, crab and herring fishing combined make up a substantial proportion of the region's total catch (approximately 31 percent in 2005 on a value basis) (Alaska DOL 2007e). There is an important connection between salmon and other wildlife and fish species on the Tongass National Forest. Crab, halibut, herring, bears, eagles, and other species depend on the annual return of millions of salmon and juvenile salmon produced in the streams and lakes of these public lands. As a result, management decisions that affect salmon are known to indirectly affect other species that are commercially fished. These relationships are, however, poorly understood and difficult to quantify. The commercial fishing discussion presented in this section, therefore, focuses on the salmon fishery. Data available for the seafood processing industry, however, do not allow for an easy distinction between salmon processors and other firms. Data presented for the seafood processing sector, therefore, include the entire seafood processing industry.

Although the profitability of the seafood industry in Southeast Alaska continuously changes, it remains a major component of the regional economy. Together, the fish harvesting and seafood processing sectors accounted for approximately 3,781 direct jobs in 2005, and approximately 10 percent of regional employment (Table 3.22-3). Indirect and induced employment for the fish harvesting sector is estimated to be 525 jobs, resulting in a total of 2,806 jobs supported by this sector in 2005. The seafood processing sector in Southeast Alaska had estimated indirect and induced employment of 960 jobs and supported a total of 2,460 jobs (Table 3.22-3).[2]

Employment data compiled by the Alaska DOL indicate that the salmon fishery accounted for approximately 45 percent of commercial fishing employment (1,026 jobs) in 2005, with the other fisheries combined supporting 1,255 jobs (Alaska DOL 2007d). Other important fisheries in 2005 included halibut (567 jobs), sablefish (226 jobs), and crab (176 jobs) (Alaska DOL 2007d).

Unlike other basic sectors of Southeast Alaska's economy, components of the seafood industry are spread throughout the region with an important presence in virtually every community. Alaska's market share of the global salmon supply (estimated at 31 percent in 1990) has, however, been falling. The loss of market share is not a function of poor stocks or low supply, but a consequence of the growing acceptability of farmed fish as a source of fresh salmon and other seafoods. Southeast Alaskan fishermen have also been negatively affected by weaker Asian markets and competition from fish from eastern Russia (Schroeder et al. 2005). Seafood processing has also undergone fundamental changes in recent years with the increased use of floating fish processing facilities and a trend toward frozen rather than canned salmon. The seafood industry is discussed in more detail in the 1997 Tongass Land Management Plan Revision Final EIS (USDA Forest Service 1997a, p. 3-452 to 3-456).

Value and volume measures of salmon harvest for Southeast Alaska are shown in Figure 3.22-8. Both measures show considerable variation from year-to-year. In contrast to revenue and catch figures, employment has remained relatively stable, but has exhibited an overall downward trend (Figure 3.22-9). Statewide, fleet participation in the Alaska salmon fisheries dropped in 2002, partly as a result of low ex-vessel prices (the prices fishermen receive for their catch), but also due to processor limitations on the number of vessels they would serve. Low prices and loss of market

[2]Note that indirect employment for the seafood processing sector includes fish harvesting. As a result, the total (direct and indirect) employment estimates for these sectors should not be added together because this would result in some salmon harvesting employment being double counted.

opportunities resulted in a notable decline in the value of limited entry permits in the salmon fisheries, declining in total value from approximately $1.25 billion in 1990 to $226 million in 2002. Wards Cove Packing Company, the eighth largest processor in Alaska, announced in December 2002 that it was terminating its Alaska salmon operations.

Southeast Alaska accounted for approximately 29 percent of employment in Alaska fisheries in 2004 (Patton and Robinson 2006). Fisheries employment in Southeast declined by about 9 percent from 2000 to 2003, but recovered slightly in 2004, increasing by 2.4 percent. Most of these changes were due to the decline and partial recovery in the salmon fishery, which accounted for approximately 45 percent of all Southeast harvesting employment in 2005 (Patton and Robinson 2006) (see Figure 3.22-9). The commercial fishing and seafood processing industries are generally characterized by high degrees of nonresident participation. Nonresidents accounted for approximately 34 percent of gross earnings in the fish harvesting industry in Southeast Alaska in 2005 (Alaska DOL 2007f). Nonresidents made up a higher share of the fish processing industry, accounting for approximately 67 percent of employment in this sector in Southeast Alaska in 2005 (Alaska DOL 2007g).

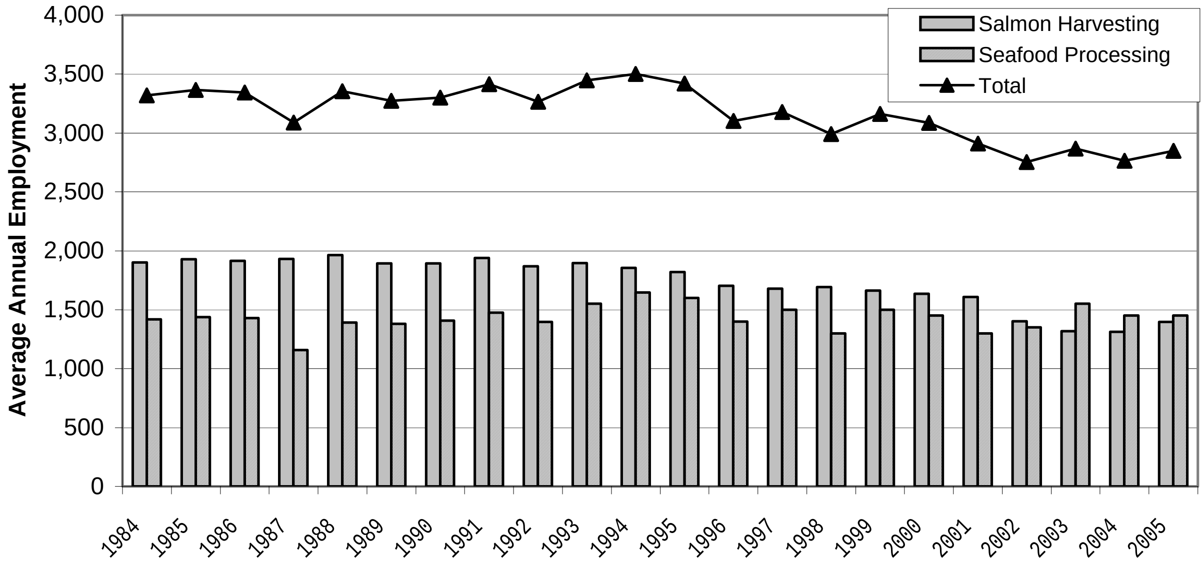
Figure 3.22-9
Direct Salmon Harvesting and Fish Processing Employment in Southeast Alaska, 1984 to 2005



1. Salmon harvesting employment totals presented in this figure were estimated based on data by Fishery and average crew sizes, time spent fishing, and preparation time for different fisheries. The employment coefficients used in this analysis are presented in Table 3-135 of the 1997 Forest Plan Revision Final EIS (USDA Forest Service 1997a).
2. Seafood processing employment for 1995 through 2005 was obtained from the Alaska DOL, who provided these data rounded to the nearest 50 employees.

Source: Alaska CFEC 2002, 2006; Alaska DOL 2001, 2006a; and USDA Forest Service 1997a (Table 3-135).

Mining and Mineral Development

Mineral exploration and mining have been a part of life in Southeast Alaska for over 120 years. Today, the mining industry is exploring new areas for potential mineral deposits and is revisiting historic mining areas using modern exploration techniques. The 1997 Forest Plan Revision Final EIS analysis noted that there are 13 identified mineral deposits on the Tongass National Forest that appeared economically viable under certain conditions. The Present Net Value of these 13 deposits was estimated at $25.6 billion (USDA Forest Service 1997a, p. 3-464). Existing and potential mining development activities identified in the 1997 Final EIS analysis included the Quartz Hill molybdenum site in Misty Fiords, the Greens Creek zinc, lead, and silver mine on Admiralty Island, and the Kensington mine north of Juneau.

In 2005, 312 workers were directly employed by the mining industry. Mining-related indirect and induced employment is estimated at 150 jobs, resulting in a total of 462 jobs supported by the mining industry in that year (Table 3.22-3). Estimated annual average employee earnings of $60,971 per year in 1995 were twice the regional average. This annual average estimate is equal to $78,043 in 2005 dollars. Based on this estimate, direct and total employee earnings in the mining sector were approximately $24.3 million and $30.4 million in 2005. Approximately 93 percent of direct mining employment was located in Juneau Borough and mainly associated with the Greens Creek Mine on Admiralty Island.

The Forest Service approved a plan of operations for the Kensington Gold Mine north of Juneau in 2005 and Coeur Alaska, Inc. subsequently began construction activities on the site. However, a lawsuit was filed against the United States Army Corps of

Engineers and the Forest Service challenging the permitted tailings disposal facility, citing violations to the Clean Water Act. The plaintiffs failed in District Court but were upheld on appeal by the 9th Circuit Court in 2007. The Forest Service anticipates the submittal of a revised plan of operations in 2008.

Natural Amenities and Quality of Life

Natural amenities and local quality of life have increasingly been recognized as important factors determining the economic prospects of many rural communities in the American West and elsewhere (Rudzitis and Johnson 2000). While local amenities and life quality do not directly generate income in the same sense as, say, a sawmill or tourist lodge, they do act to attract and keep residents. This, in turn, supports communities and their economies in several ways. First, many of these residents may earn a substantial proportion of their income from non-job related sources that are independent of local economic activity. Much of this income will then be spent locally, resulting in additional employment and income in the community. Second, residents bring with them important skills and energy that constitute valuable assets for the community. Broadly termed “human capital” by economists, these skills (and the energy with which residents apply them) can earn additional outside income as well as provide essential social resources to the community. These residents may also help attract and retain businesses that are dependent on a skilled labor force, but otherwise relatively footloose from a location standpoint.

Since it is tracked as a separate category in standard income statistics, non-wage income and its contribution to local economies is directly measurable. Investment income (dividends, interest, and rent) and transfer payments from government represent the two major categories of non-wage income. As shown in Table 3.22-10, non-job related income (i.e., transfer payments and dividends, interest, and rent) accounted for 35 percent of total income in Southeast Alaska in 2000, compared to 17 percent in 1980. Non-job related income in the state of Alaska as a whole exhibited a similar change over this period, increasing from 16 percent to 33 percent of total income. Non-job related income accounted for 31 percent of total income for the United States as a whole, but showed relatively little change over the past two decades increasing from 28 percent of total income in 1980 (Table 3.22-10).

Data compiled for 2005 indicate that the non-wage income as a share of total income has decreased from 2000 to 2005 in Southeast Alaska, Alaska as a whole and in the U.S. (Table 3.22-11). In Southeast Alaska this decrease is entirely in dividends, interest, and rent, with transfer payments increasing as a share of total income over this period. This was also the case for the U.S. as a whole. Both non-wage categories decreased in Alaska.

Table 3.22-10
Components of Per Capita Income, 2000

	Southeast Alaska			Alaska			United States		
	2000		% Change	2000		% Change	2000		% Change
	Total ($)	Percent of Total	1980-2000	Total ($)	Percent of Total	1980-2000	Total ($)	Percent of Total	1980-2000
Personal income	31,243	100	0	29,642	100	0	29,469	100	0
Earnings	20,270	65	-18	19,861	67	-18	20,287	69	-3
Transfer payments	4,793	15	9	4,801	16	10	3,793	13	1
Dividends, interest, and rent	6,180	20	9	4,980	17	7	5,389	18	2

Notes:
1. Earnings includes wages and salaries, other labor income, and proprietors' income.
2. Transfer payments consist mainly of government payments to individuals, including retirement, disability, and unemployment insurance benefit payments, income maintenance payments, and veterans benefit payments. Government payments to individuals in Alaska include Alaska Permanent Fund benefits, which are derived from oil revenues and paid to every resident.
3. 1980-2000 Change is the change in percentage share of total per capita income (e.g., earnings in Southeast Alaska in 1980 comprised 83 percent of total per capita income compared to 65 percent in 2000, a difference of 18 percent). In inflation-adjusted dollars this represented a 14 percent decrease from $23,597 to $20,270.

Transfer payments can be further broken out into various categories with social security payments and medical benefits being among the most important. Transfer payments per capita in 2005 in Southeast Alaska were slightly higher than the U.S and Alaska averages (Table 3.22-11).

“Other payments” comprised approximately 40 percent of per capita transfer payments in Southeast Alaska and Alaska in 2000, compared to less than 1 percent nationwide (Table 3.22-12). This category includes certain income categories that are directly linked to birthrights or residence in Alaska, notably annual payments from the Alaska permanent fund, which have averaged between $1,000 and $2,000 per resident in recent years, and dividends from various Alaska native corporations, which are variable but often quite substantial. Much of the growth in transfer payments in Southeast Alaska and Alaska between 1980 and 2000 was due to increases in the other payments category, which exhibited a more than five-fold increase over this period. Other payments comprised a smaller share of total Southeast Alaska transfer payments in 2005 (Table 3.22-13).

Table 3.22-12
Components of Per Capita Transfer Payments, 1980 and 2000

Retirees comprise the most common (but by no means the only) source of non-wage income in many rural communities (Colt 2001). In fact, this has given rise in some places to local marketing strategies specifically aimed at attracting retirees and thereby developing the local "retirement industry." The growing economic importance of retirees was not readily apparent in Southeast Alaska in Table 3.22-12 because the increase in the "other payments" category tends to overshadow other changes. However, although retirement and disability payments comprise a relatively small share of total income by national standards, they almost doubled over this period, while medical payments increased by approximately 300 percent. This is partially the result of natural aging processes, but the mean age in the study area, and Alaska as a whole, has been rising at a much faster rate than elsewhere in the United States. This, in turn, may serve as a partial indication that Alaska is becoming more attractive for people as a place to live and not merely as a place to earn money.

Retirement and disability payments and medical payments increased in Southeast Alaska in absolute terms and as a share of transfer payments between 2000 and 2005 accounting for 64 percent of Southeast Alaska transfer payments in 2004, compared to 79 percent nationwide (Table 3.22-13).

The role of “human capital” in local economies is not directly measurable, but it is undoubtedly substantial. The skills possessed by a community’s population can be essential in determining its adaptability to negative changes and its ability to take advantage of new economic opportunities. Skilled employees, for example, constitute a key resource for existing or potential employers, and local entrepreneurs can help identify and grow new business opportunities if they exist. Owing to improvements in transportation and telecommunications, other residents may be able to sell their skills in distant or “virtual” labor markets without leaving home. Equally important is the skills and energy residents can bring to local government and other community organizations. Research has indicated that effective and energetic local government supported by strong community involvement is an important ingredient in community resiliency and the ability to weather adverse economic events.

Although it is difficult to directly measure the importance of natural amenities in attracting and keeping residents, proximity to natural environments and the recreational activities they support are undeniably a benefit enjoyed by residents, especially in the more rural communities of Southeast Alaska. At the same time, the atmosphere of a community also constitutes an important amenity, and this may often be linked to more traditional forms of economic activity, such as fishing or timber. In other words, changes in the local economy such as a shift to tourism may impact local atmosphere and amenities even if the surrounding natural environment remains essentially unchanged. These impacts are often assumed to be negative as tourism leads to crowding and the loss of traditional charm, but this need not always be the case. Certain tourism establishments, such as restaurants, meeting centers or entertainment facilities, often serve local residents as well, and thus add to the amenities available to them. Finally, the size of a community has important effects on the local amenities available. If a community is too small, or too poor, for example, it may not be able to provide many of the basic social and economic amenities many residents require, local natural amenities notwithstanding.

Payments to the State

Prior to 2000, in states with national forests, 25 percent of the returns to the US Treasury from revenue producing Forest Service activities such as timber sales, were returned to each state for distribution back to counties (or in Alaska, boroughs) having acreage within a national forest. Those payments were called the “25 percent fund payments” and were dedicated by law to be used for roads and schools. In October 2000, the *Secure Rural Schools and Community Self Determination Act of 2000* was enacted to stabilize federal payments to states in response to declining federal receipts.

The legislation was authorized for implementation for fiscal years 2001 through 2007 and allowed counties and/or boroughs to choose between 25 percent of current receipts or a full payment amount based on the average of the highest three payments made to the state during the 14-year period between 1986 and 1999. Alaska boroughs and communities have elected to receive a full payment amount rather than 25 percent of receipts since enactment of this legislation. Those annual full payment amounts are primarily dedicated to roads and schools, with provisions for special project funding under certain conditions. Under the full payment approach, Forest Service payments to the State of Alaska have been based on the high 3-year historic average, rather than linked to annual Forest Service revenue, and, as a result, Alaska has received payments of approximately $9 million per year. Payments made to the state of Alaska from 1986 through 2007 are shown in Table 3.22-14.

Table 3.22-14
Federal Payments to Alaska from NFS Receipts 1986 to 2006 (Amounts in $1,000s)

Year	Payment ($000s)[1]
1986	820.2
1987[2]	0.0
1988	581.4
1989	6,892.6
1990	11,703.0
1991	11,870.3
1992	4,216.7
1993	4,847.0
1994	10,764.7
1995	9,053.9

Environmental Consequences

This section describes the potential direct, indirect, and cumulative economic effects of the seven alternatives examined in detail in the EIS. The analysis is divided into two main sections: 1) economic impact analysis, and 2) economic efficiency analysis. The Tongass National Forest budget and payments to the State are addressed in two short sections at the end. In addition, a fifth and final section summarizes the cumulative effects which are included in the overall analysis.

The impact analysis section addresses the effects of the proposed alternatives on regional employment and income. The efficiency analysis attempts to measure all of the costs and benefits to society, both future and present, of each alternative. The costs and benefits assessed in an economic efficiency analysis are not restricted to cash transactions, but also include non-market benefits such as consumer surplus. The concepts and methodologies used in each of these analyses are described in detail in the following sections. In general, it should be remembered that impact and efficiency analyses measure different things and are not directly comparable. Alternatives with positive impacts on jobs and income will not necessarily have high benefits under efficiency analysis.

The cumulative effects of the alternatives are assessed as part of the impact and efficiency analyses in the following sections. These effects are addressed in a number of ways including the following: The regional economic overview in the Affected Environment portion of this section addresses the regional economy as a whole to establish context for this analysis. Potential changes in the wood products industry are viewed in the context of ongoing changes in other sectors of this industry, particularly past and projected future trends in logging on Native corporation lands.

Effects on the recreation and tourism industry are viewed in the broader context of ongoing and possible future trends in visitation to Southeast Alaska. The effects analysis also considers the economic implications of the potential effects of the alternatives on possible future transportation and public utility projects.

Economic Impact Analysis

The Economic Impact Analysis addresses the effects of the alternatives on regional employment and income.

This section addresses the potential effects of the proposed alternatives on regional employment and income and is divided into seven main parts. The first six parts address the effects of the alternatives on the wood products industry, recreation and tourism, mining, transportation and utilities, salmon harvesting and processing, and quality of life, respectively. The final part provides a summary of the effects discussed in the preceding sections.

Wood Products and Timber Demand—Long-Term Effects

The economic impact analysis addresses the potential effects of the alternatives on the wood products sector in two ways. This section evaluates the long-term impacts of the proposed alternatives based on the four projected demand scenarios developed by Brackley et al. (2006a). The following section (Wood products—Short-Term Effects) discusses the short-term implications of the alternatives by addressing their potential effects on national forest timber sale volume under contract, as well as NEPA-cleared volume and timber volume in preparation.

The potential effects of the alternatives on the future supply of national forest timber may be evaluated based on the amount of timber available under each alternative. The ASQ is the maximum quantity of timber that may be harvested from suitable lands on the entire Forest for a 10-year period (36 CFR 219.3). It is usually expressed as an annual average. In addition to the volume harvested from suitable lands, timber harvested from unsuitable lands can also contribute to market demand needs. The Forest contains extensive areas of young-growth forest that are in the stem exclusion phase (see the *Timber* section of this EIS). Thinning these dense stands to improve wildlife habitat may result in merchantable volume. Other examples include timber that may be salvaged from unsuitable land following windthrow if these trees are in excess to dead and down wood habitat needs and timber from harvest on oversteepened slopes that is incidental to other harvest operations.

As discussed earlier, the ASQ is a ceiling and does not represent a future sale level projection or target, nor does it reflect all of the factors that may influence future sale levels. This is discussed further in the *Timber* section of this document. As noted in the Affected Environment portion of this section, the ASQ consists of two non-interchangeable components (NICs): NIC I, which includes lands that can be harvested with normal logging systems, and NIC II, which includes lands with especially high logging costs usually due to isolation or special harvesting equipment requirements. Acres included in the ASQ but not in NIC I are more costly to harvest and not likely to be cut under current market conditions with the current industry structure.

Estimated annual average ASQ and NIC I volumes are presented by alternative for the second decade following implementation in Table 3.22-15. These volumes are divided into general log class and species type based on recent estimates of the net standing volume by species and grade for the Tongass National Forest (Alexander 2006). This table also includes projected non-national forest annual harvests for Southeast Alaska, which are assumed to be 109 MMBF based on Brackley et al. (2006a). Harvest from private lands accounts for the largest share (102 MMBF) of the non-national forest harvest, with harvest from other public lands accounting for the remaining 7 MMBF. This overall estimate is lower than the volume harvested from non-national forest lands in 2004 (123 MMBF) and 2005 (147 MMBF) and lower than estimates of future non-national forest harvest developed by the McDowell Group et al. (118 MMBF) (McDowell

Group et al. 2004)[3]. Non-national forest harvest decreased from 221 MMBF in 2000 to 123 MMBF in 2005 (Figure 3.22-5). As previously noted, harvests from private lands are typically exported as logs and are not processed locally.

Table 3.22-15

Total Southeast Alaska	**158**	**252**	**296**	**423**	**348**	**345**	**479**

[1] The No.1 Spruce/Hemlock category also includes peeler and select logs.
[2] The 109 MMBF consists of 102 MMBF from private lands and 7 MMBF from other public lands. Harvest from private lands is assumed to be exported in log form and not processed in Southeast Alaska. Non-Tongass harvest levels are assumed constant across alternatives and time periods.
NIC I=Non-Interchangeable Component I. NIC I includes lands that can be harvested with normal logging systems.

The following discussion is divided into two main sections. The first section addresses the potential effects of the alternatives on the timber industry. The second section discusses the potential effects the alternatives would have on timber-related employment and income in Southeast Alaska.

Effects on the Timber Industry

The following sections evaluate the alternatives with respect to: a) the Pacific Northwest Research Station demand projections (Brackley et al. 2006a), and b) current production levels, installed capacity, and the minimum volumes required by various processing facilities.

Demand Indicators

Pacific Northwest Research Station Projections

The Affected Environment part of this section provides an overview of current conditions for the Southeast Alaska wood products industry, outlines the current status of the industry, and discusses projected demand, as identified by Brackley et al. (2006a) (see Table 3.22-6). One key difference between the demand projections prepared by Brackley et al. and those used in past Tongass National Forest planning efforts (Brooks and Haynes 1990, 1994, 1997) is that the Brackley et al. (2006a) publication presents four specifically designed scenarios, as opposed to three general

[3] McDowell Group (2006b) clarified and provided some updated information on their 2004 study and noted that they now understand that respective annual harvests from private and state lands are likely to be closer to 50 MMBF and 10 to 13 MMBF into the future, respectively.

assumptions of long-term demand. In addition, Brackley et al. (2006a) estimated demand in two scenarios for decked logs and a portion of cedar exports only, not total harvest, as done in previous projections (see the Affected Environment part of this discussion).

The four scenarios are generally described as limited lumber, expanded lumber, medium integrated industry, and high integrated industry. A key issue in these scenarios is the use of low-quality material (low-grade and utility logs). The limited and expanded lumber scenarios both assume that this material will be left in the Forest, sent directly to sawmill chippers, shipped to the lower 48 states, or exported. The local wood products industry is assumed to consist primarily of sawmills that process higher value material and it is assumed that the economic disposition of lower value material (No. 3 sawlogs and utility logs) will continue to be a challenge. The two integrated industry scenarios, in contrast, assume the addition of one or more facilities that will process this low-quality material. Facilities that could be developed to process lower quality material include veneer, medium density fiberboard (MDF), and bioenergy facilities among others. The four different scenarios result in total derived demand projections that range for the year 2022 from 68 MMBF under Scenario 1 (Limited Lumber Production) to 342 MMBF under Scenario 4 (High Integrated Industry) (Table 3.22-7).

These scenarios provide a good basis for discussion of where the industry currently is, and provide insight into what that industry could look like in the future given various assumptions about industry investment and end markets. Of course many factors would be involved to shape what the actual industry looks like in the future. The "seek to provide a supply of timber from the Tongass National Forest" language of the TTRA indicates the Forest should consider a full range of possibilities. The four scenarios evaluated by Brackley et al. are useful in this context, especially as the Deciding Official works to balance the land base available to provide timber along with all other resource values and needs. These four scenarios are hypothetical and presented here to illustrate the type of developments that might take place in cases where different volumes are made available for harvest. An implicit assumption of all four scenarios is that an economically viable and stable timber supply is available from multiple sources in Southeast Alaska, including the Tongass National Forest. The transition from one scenario to the next involves new private investment and market development. A key factor in attracting new investment is whether or not a supply of timber "shelf volume" is available for purchase.

The four scenarios provide one series of benchmarks that the proposed alternatives may be measured against. Recognizing that the Southeast Alaska wood products industry has essentially been in a period of transition since the APC and KPC pulp mills closed in the 1990s, the alternatives evaluated in this document also consider alternate futures for the industry, with Alternatives 1 through 4 designed to correspond with Brackley et al.'s Scenarios 1 through 4, while also responding to other concerns. Alternative 5, No Action, is the current Forest Plan (1997 ROD, as amended). Alternative 6, Proposed Action, is also based on the existing plan, but includes adjustments based on information generated during the recent 5 Year Plan Review and other minor clarifications and updates. Alternative 7 assumes that all wood processed in Southeast Alaska would come from the Tongass National Forest.

Scenario 1 – Limited Lumber Production. This scenario approximates the status of the timber industry in Southeast Alaska at the time that the Brackley et al. study was completed. Transition of the industry from the pulp mill era, which involved a much more integrated industry, toward an industry that is centered around the manufacture and supply of a different suite of products has been slow. Uncertainty about a stable supply of timber from the Tongass is believed to have contributed to the timeframe of this transition.

Total derived demand is projected to be 68 MMBF in 2022 under this scenario (Table 3.22-7). It is likely that this volume would be primarily logs from more economical (NIC I) lands. Existing mills would continue to have insufficient timber to operate efficiently. The lower value logs sold in federal, state, and private timber harvest projects would continue to be left in the woods, exported, or chipped and sold when favorable markets conditions exist.

> Alternative 1 with a maximum annual average harvest level of 49 MMBF could not provide sufficient volume to meet this scenario as currently modeled.
>
> Alternatives 2, 3, 4, 5, 6, and 7 could all provide sufficient volume to meet this scenario during the next 10 to 15 years.

Scenario 2 – Expanded Lumber Production. This scenario also projects only higher value logs are processed, with limited new investments in the existing mills in Southeast Alaska. The scenario assumes that there will be sufficient sawlog wood supply, primarily from federal and state timber lands, to efficiently operate the existing mills in Southeast Alaska. No new mills will be installed to utilize the lower value logs from any lands in Southeast and this material could be left in the woods, exported, or chipped and sold when favorable market conditions exist..

Total derived demand is projected to be 187 MMBF in 2022 under this scenario (Table 3.22-7). As in Scenario 1, it is likely that this volume would be primarily higher value logs from the more economical (NIC I) lands.

> Alternatives 1 and 2 with maximum annual average harvest levels of 49 MMBF and 151 MMBF, respectively, could not provide sufficient volume to meet this scenario.
>
> Alternatives 3, 4, 5, 6, and 7 could all provide sufficient NIC I volume to meet this scenario.

Scenario 3 – Medium Integrated Industry. This scenario builds on Scenario 2 and would establish processing capacity to fully utilize sawlogs and low grade and utility logs from federal and state timber sales. Under this scenario the current sawlog milling capacity would operate efficiently and new processing capacity would be developed to utilize the material that has been left in the woods or exported. Some material from other land ownerships has the potential to be used by local mills. Low-grade logs would be used to produce chemicals, energy, or engineered wood products.

Total derived demand is projected to be 204 MMBF in 2022 under this scenario (Table 3.22-7). It is likely that this volume would come from both the more economical (NIC I) lands and the less economical (NIC II) lands.

> Alternatives 1 and 2 with maximum annual average harvest levels of 49 MMBF and 151 MMBF, respectively, could not provide sufficient volume to meet this scenario.
>
> Alternatives 3, 4, 5, 6, and 7 could provide sufficient volume to meet this scenario.

Scenario 4 – High Integrated Industry. This scenario builds on Scenario 3 and provides an estimate of the upper market level for the foreseeable future. In order for this situation to be realized, new investments in processing capacity would need to be made and additional market shares established.

Total derived demand is projected to be 342 MMBF in 2022 under this scenario (Table 3.22-7). It is likely that this volume would come from both the more economical (NIC I) lands and the less economical (NIC II) lands. Note that Brackley et al. (2006a) indicate that it would likely take several years to fully achieve Scenario 4.

Alternatives 1, 2, 3, 5 and 6 with maximum annual average harvest levels of 49 MMBF, 151 MMBF, 205 MMBF, 267 MMBF, and 267 MMBF respectively, could not provide sufficient volume to meet this scenario.

Alternatives 4 and 7 could provide sufficient volume to meet this scenario.

The ability of the seven alternatives to supply enough timber to satisfy the projected demand for timber under each scenario is summarized in Table 3.22-16.

Table 3.22-16
Ability of the Alternatives to meet the Timber Demand Scenarios in 2022

	Alternative[1]						
	1	2	3	4	5	6	7
Scenario 1	No	Yes	Yes	Yes	Yes	Yes	Yes
Scenario 2	No	No	Yes	Yes	Yes	Yes	Yes
Scenario 3	No	No	Yes	Yes	Yes	Yes	Yes
Scenario 4	No	No	No	Yes	No	No	Yes

1. While an alternative may be technically able to meet a given demand scenario, the ability to do so in the short-term is highly dependant on budgets, resolution of current litigation and success in implementing new projects. It takes several years to initiate and complete a new analysis and implement the decision through sale layout and contract award.

Current Production Levels, Installed Capacity, and Minimum Volumes Required by Various Processing Facilities

The following sections evaluate the potential effects of the alternatives using three sets of evaluation criteria: current production levels, installed capacity, and the minimum volumes required to operate by various processing facilities. Current (2005) production levels and active and total installed capacity are shown by facility in Table 3.22-5.

The minimum timber volumes required by various processing facilities are identified in Table 3.22-17. These minimum estimated volumes are compared with the estimated annual ASQ for the second decade following Plan implementation for each alternative in Figure 3.22-11. As shown in Table 3.22-18, the different types of potential facilities would use different types of logs, although in most cases different types of logs may be used by more than one type of facility. Both sawmills and a veneer plant would, for example, be able to process No. 2 spruce and hemlock sawlogs (Table 3.22-18). In addition, different facilities would be able to process more than one type of log. A veneer plant may, for example, process No. 2 spruce and hemlock sawlogs, No. 3 spruce and hemlock sawlogs, and cedar (Table 3.22-18). These points should be kept in mind when viewing the simplified comparison presented in Figure 3.22-11.

Table 3.22-17
Minimum Timber Volumes Required by Various Processing Facilities

Facility	Volume (MMBF)
Sawmills[1]	138
Veneer Plant[2]	30
MDF or Bioenergy[2]	80 to 100

[1] The estimated sawmill volume is approximately 66 percent of existing mill capacity based on the four largest existing sawmills, with some allowance for smaller sales. It is not 66 percent of the estimated mill capacity shown in Table 3.22-5.
[2] These volumes are the minimum required to operate the identified types of facilities.

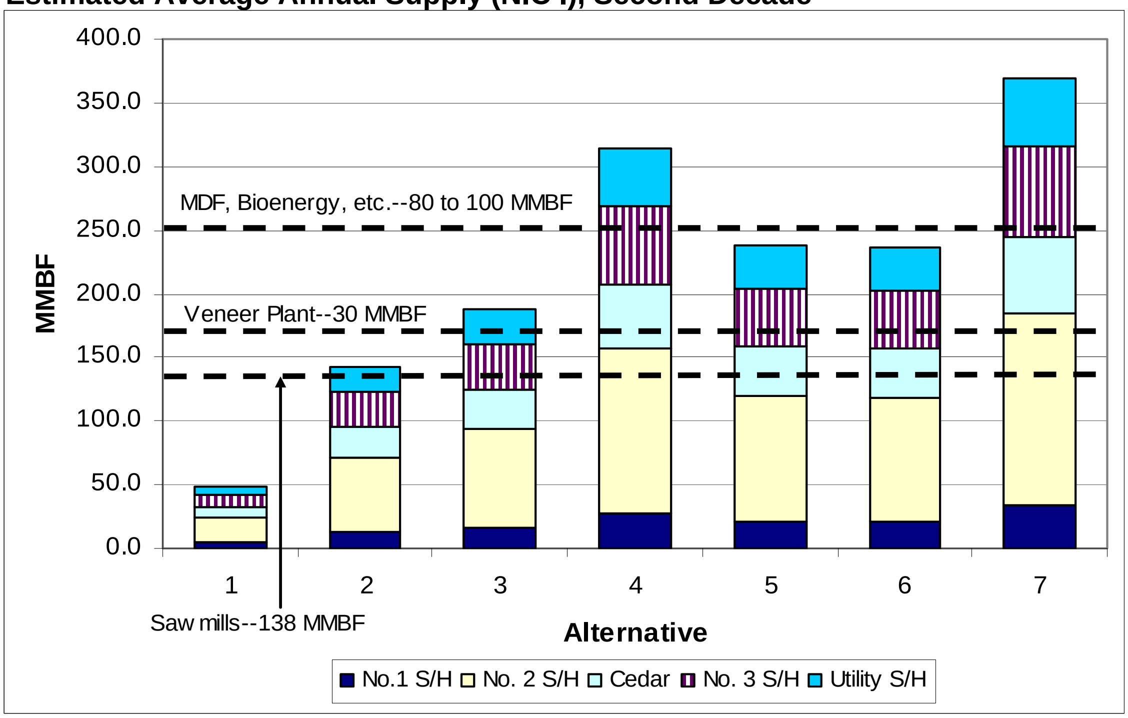
Figure 3.22-11
Minimum Timber Volumes Required by Various Processing Facilities and Estimated Average Annual Supply (NIC I), Second Decade



Notes:
S/H = Spruce/Hemlock
1. No. 1 S/H includes Peeler, Select, and No.1 spruce and hemlock sawlogs.
2. The minimum timber volumes required by various processing facilities are shown in Table 3.22-17. Log utilization by facility is shown in Table 3.22-18.
3. Estimated supply by alternative is based on the projected ASQ and average timber sale composition in terms of species and log grades (see Table 3.22-15).

Table 3.22-19
Projected Second Decade NIC I Volumes and Active and Total Installed Capacity

	Alternative						
	1	2	3	4	5	6	7
Log Grade/Species	**Projected NIC I (MMBF Log Scale)**						
Higher Value[1]	24	72	94	157	119	118	185
Cedar[2]	8	23	30	51	39	38	60
Lower Value[3]	9	27	36	60	46	45	71
Utility	7	21	27	46	35	34	54
Total	**49**	**143**	**187**	**314**	**239**	**236**	**370**
Capacity	**Percent of 2006 Active and Total Installed Capacity**						
Active Installed Capacity[4]	9%	27%	36%	60%	46%	45%	71%
Total Installed Capacity[5]	7%	20%	26%	43%	33%	33%	51%

Notes:
1/Higher value consists of No.1 and No.2 Spruce/Hemlock (see Table 3.22-15)
2/Cedar includes Alaska yellow-cedar and Western red-cedar (see Table 3.22-15)
3/Lower value includes No. 3 Spruce/Hemlock (Table 3.22-15)
4/Active installed capacity was 261 MMBF in 2005 (Table 3.22-5)
5/Total installed capacity was estimated at 361 MMBF in 2006 (see Table 3.22-5, Note 1)

Alternative 1—The maximum annual average timber harvest under Alternative 1 would be approximately 49.3 MMBF per year in the second decade, with a NIC I component of approximately 48.8 MMBF. This harvest level could be met in the first year if this alternative was selected and the timber volume presently under litigation was made available for harvest. As of September 2007, there was 43.5 MMBF under active litigation, with an additional 165 MMBF withdrawn under the 2007 Natural Resources Defense Council settlement until completion of this forest planning process.

Based on the typical log mix for the Tongass National Forest, the NIC I volume would include approximately 24 MMBF of higher-value spruce and hemlock logs (peeler/select, No. 1, and No. 2), 8 MMBF of cedar logs, and 16 MMBF of lower-value spruce and hemlock sawlogs (No. 3 and utility) (Table 3.22-19). This volume would not be sufficient to support the existing Southeast Alaska sawmills operating at their recent production levels (32.1 MMBF in 2006). Further, the Southeast Alaska sawmill industry is currently operating at less than 14 percent of the active mill capacity and less than 10 percent of total installed capacity (Table 3.22-19).

Viewed in terms of the minimum timber volumes required by various processing facilities, this volume would be insufficient to meet the estimated sawmill requirement of 138 MMBF of high value timber (Table 3.22-17). The available supply of higher-quality material (including cedar) would account for about 32 MMBF of the total harvest under this alternative (Table 3.22-15). There would be sufficient volume to support a veneer plant (30 MMBF) if 14 MMBF or more of No. 2 spruce/hemlock sawlogs were processed by this type of plant, rather than the existing sawmills. The projected supply of No. 3 spruce/hemlock sawlogs (9 MMBF) and utility logs (7 MMBF) would not be sufficient to support a chip related facility, such as a MDF plant.

This alternative would not meet the potential upper planning cycle demand of 360 MMBF.

Alternative 2—The maximum annual average harvest level under Alternative 2 would be approximately 151 MMBF per year in the second decade, with a NIC I component of approximately 143 MMBF. Based on the typical log mix for the Tongass, the NIC I volume would consist of approximately 72 MMBF of higher-value logs, 23 MMBF of cedar logs, and 48 MMBF of lower-value sawlogs and utility logs (Table 3.22-19).

This volume would be sufficient to support the existing Southeast Alaska sawmills operating at their current production levels (32.1 MMBF in 2006). The estimated higher-value component under this alternative (72 MMBF) would allow regional sawmills to operate at approximately 27 percent of the active installed processing capacity and 20 percent of total installed production capacity in 2006 (Table 3.22-19).

Viewed in terms of the minimum timber volumes required by various processing facilities, this volume would be insufficient to meet the estimated sawmill requirement of 138 MMBF of high value timber. However, if all the sawlogs were to go to existing sawmills, these mills would operate at a higher rate than they are at present, and assuming their ability to use the lower grade sawlogs more efficiently, approximately 100 MMBF would be available for processing under this alternative. Improved efficiency could result from investments in existing equipment or new capacity. If the existing sawmills were not to operate at this level and processed only higher grade sawlogs, there would be sufficient volume to support a veneer plant.

This alternative would not meet the potential upper planning cycle demand of 360 MMBF.

Alternative 3—The maximum annual average harvest level under Alternative 3 would be approximately 205 MMBF per year in the second decade, with a NIC I component of approximately 187 MMBF

Based on the typical log mix for the Tongass, the NIC I volume would consist of approximately 94 MMBF of higher-value logs, 30 MMBF of cedar logs, and 63 MMBF of lower-value sawlogs and utility logs (Table 3.22-19). This volume would be sufficient to support the existing Southeast Alaska sawmills operating at their current production levels (32.1 MMBF in 2005). The estimated higher-value component of the ASQ under this alternative (94 MMBF) would allow regional sawmills to operate at approximately 36 percent of the active installed processing capacity and 26 percent of total installed production capacity calculated in 2006 (Table 3.22-19).

Viewed in terms of the minimum timber volumes required by various processing facilities, this volume would not have enough high grade sawlogs to meet the estimated sawmill requirement of 138 MMBF of high value timber. However, similar to Alternative 2, if all sawlogs were to go to the existing sawmills they would operate at a higher rate and use lower grade sawlogs more efficiently. There would also be enough volume to support a veneer plant and export the remainder; support two veneer mills; or operate an MDF or similar facility. Over the long-term, a relatively stable level of harvest around the 185 MMBF range would be expected to encourage the development of a moderate level of integration for the local industry.

This alternative would not meet the potential upper planning cycle demand of 360 MMBF.

Alternative 4—The maximum annual average harvest level under Alternative 4 would be approximately 360 MMBF per year in the second decade, with a NIC I component of approximately 294 MMBF. This is the second highest projected volume in any of the alternatives. Alternative 7 has the highest.

Based on the typical log mix for the Tongass, the NIC I volume would consist of approximately 157 MMBF of higher-value logs, 51 MMBF of cedar logs, and 106 MMBF of lower-value sawlogs and utility logs (Table 3.22-19). The estimated higher-value component would allow regional sawmills to operate at approximately 60 percent of active installed processing capacity and 43 percent of total installed production capacity calculated in 2006 (Table 3.22-19).

Viewed in terms of the minimum timber volumes required by various processing facilities, this volume would be sufficient to meet the estimated sawmill requirement of 138 MMBF of high value timber and the estimated veneer plant requirement of 30

MMBF. There would also be available cedar to either run through the existing sawmills or support a new mill that specializes in cedar. In addition, the available supply of low grade sawlogs and utility logs would be sufficient to support a chip related facility, such as an MDF plant.

As industry becomes more integrated, it is possible that the veneer plant and chip related operations would expand operations to efficiently take advantage of this excess material. There could also be additional new investment in sawmills in the region, with, for example, investment in new facilities closer to sources of raw materials, which would reduce transportation costs. The amount of cedar harvested may continue to exceed the local capacity to process it, but investments in production of high end wood products may reduce the amount that is surplus.

This alternative would not meet the potential upper planning cycle demand of 360 MMBF.

Alternative 5, No Action and Alternative 6, Proposed Action—The maximum annual average harvest levels under Alternative 5 and 6 would be approximately 267 MMBF under either alternative, with respective NIC I components of approximately 239 MMBF and 236 MMBF, respectively. These alternatives are midway between Alternatives 3 and 4 in terms of projected volume.

Based on the typical log mix for the Tongass, the volume for these alternatives would be comprised of approximately 119 MMBF of higher-value logs, 39 MMBF of cedar logs, and 81 MMBF of lower-value sawlogs and utility logs (Table 3.22-19). The estimated higher-value component would allow regional sawmills to operate at approximately 45 percent of the active installed processing capacity and 33 percent of total installed production capacity calculated in 2006 (Table 3.22-19).

Based on the existing active installed sawmill processing capacity, these alternatives would almost provide sufficient higher-value timber supply for existing sawmills to operate at or near full capacity. There would be sufficient timber to operate the existing sawmills at or near full capacity if they were also able to process cedar. The total projected NIC I volume under these alternatives would not be quite sufficient to support a fully integrated industry. There would be sufficient volume to support one or more veneer plants or an MDF or other chip-related operation, but not both.

These alternatives would not meet the potential upper planning cycle demand of 360 MMBF.

Alternative 7—The maximum annual average harvest level under Alternative 7 would be approximately 421 MMBF per year in the second decade, with a NIC I component of approximately 370 MMBF. This is the highest projected volume under any of the alternatives.

Based on the typical log mix for the Tongass, the NIC I volume would be comprised of approximately 185 MMBF of higher-value logs, 60 MMBF of cedar logs, and 125 MMBF of lower-value sawlogs and utility logs (Table 3.22-19). The estimated higher-value component represents approximately 71 percent of the active installed processing capacity and 51 percent of total installed production capacity in 2006 (Table 3.22-19).

Viewed in terms of the minimum timber volumes required by various processing facilities, Alternative 7 would be sufficient to meet the estimated sawmill requirement of 138 MMBF of high value timber and the estimated veneer plant requirement of 30 MMBF. There would also be cedar available to run through the existing sawmills or support a new mill that specializes in cedar. In addition, the available supply of low grade sawlogs and utility logs would be sufficient to support one or more chip related facilities, such as an MDF plant.

The potential effects under this alternative would be similar to those described for Alternative 4 above. Although there would be more volume available under Alternative 7 than under Alternative 4, the general trend would be expected to be the same and is based on the assumption that a reliable supply of timber would allow the development of an integrated industry and encourage the development of new facilities and the utilization of existing facilities. This alternative also assumes that all wood processed in Southeast Alaska would come from the Tongass National Forest. As with Alternative 4, the highly integrated nature of the timber industry that could be supported by this level of projected harvest could involve the entry of more businesses and/or facilities in Southeast Alaska. As industry becomes more integrated, it is possible that the veneer plant and chip related operations would expand operations to efficiently take advantage of this excess material. There could also be additional new investment in sawmills in the region, as discussed with respect to Alternative 4.

This alternative would meet the potential upper planning cycle demand of 360 MMBF.

Discussion

How the timber industry would respond to a stable supply of timber under any of the alternatives described above is speculative. The projected scenarios are based on the assumption that as stable volumes increase, the industry will develop in an integrated fashion, with operations and production that utilize materials that are inefficient or excess to one another's production needs. An integrated industry could also promote the establishment of other businesses that provide both direct and indirect support services, such as lumber and/or specialty wood product grading and certification. Coordinated or consolidated marketing of Alaskan wood products could be another example of integrated operations.

Several developments hold promise for the timber industry in Southeast Alaska regardless of which harvest level stabilizes. A wood-burning boiler is being installed by the community of Craig to heat school buildings and a recreation facility, reducing energy costs by utilizing waste wood. Several other communities have shown interest in this type of system. Investments in dry kilns and planers in several facilities suggest an increase in production of high value wood products. Wood technology and testing has helped secure a set of Alaska lumber grades for Alaska species. Hemlock, for example, with the Alaska lumber grade can now compete directly with Douglas fir construction grade lumber. To take best advantage of this, the lumber needs to be dried, planed and graded. In Alaska alone, the construction lumber market consumes approximately 120 MMBF per year.

Once positioned, Southeast Alaskan facilities could tap into that high end market, which is currently supplied by material imported from the lower 48 states. Other examples include development of specialty and finished wood products from hemlock and development of dried, sawn, and finished house kits. Products such as glue laminated materials are being tested and show promise. Specialty products made of yellow-cedar are currently marketed internationally. Collective marketing of local wood products could have a positive impact on sales of locally produced material. With a stable supply of material, it might be possible for the local wood industry to regain market share in world wide wood product markets, as well as continue to develop niche markets that take advantage of the high quality and uniqueness of Alaska woods.

Employment and Income

Projected levels of employment and income are presented by alternative in Table 3.22-20. These estimates are based on the annual average NIC I component of the ASQ. Direct employment is calculated using a coefficient of 3.31 jobs/MMBF for sawmill employment and 2.31 jobs/MMBF for logging employment (Alexander 2007). These coefficients are based on average levels of forest-related employment per unit of net sawlogs harvested on the Tongass for the 2000 to 2005 period. This time period excludes volume from long-term contracts and the employment volatility of the late 1990s, and is, therefore, representative of current conditions. Total employment is calculated using regional multipliers estimated using IMPLAN. (See note 6 in Table 3.22-20 for an explanation of the difference between the various multipliers).

The estimates presented in Table 3.22-20 assume the entire NIC I component for the first decade would be harvested. They also assume a linear relationship between harvest and employment levels, with a one percent change in harvest resulting in a one percent change in employment. In reality, changes in volume will have a lagged response in employment, but this assumed linear relationship is an approximation that can be used to compare alternatives. Estimated changes in sawmill and logging employment are presented in job-years, which represent the equivalent of one year's employment. This potential employment would not necessarily occur all in one year and estimated job totals do not directly translate into estimated numbers of affected workers.

The logging employment totals identified in Table 3.22-20 also include jobs associated with non-Tongass National Forest harvest activities. Non-Tongass harvest in Southeast Alaska is assumed to be 109 MMBF for all alternatives and, with the exception of the approximate 7 MMBF harvested from state lands, is assumed for the purposes of this analysis to be exported in unprocessed form (Brackley et al. 2006a). As noted in a preceding section, this estimate is lower than the volume harvested from non-national forest lands in 2004 (123 MMBF) and 2005 (147 MMBF), and lower than estimates of future non-national forest harvest developed by the McDowell Group et al. (118 MMBF) (McDowell Group et al. 2004).[4]

Assuming the entire NIC I component were harvested over the next decade, average annual direct wood products employment would range from 494 annualized jobs under Alternative 1 to 1,922 jobs under Alternative 7. Approximately 226 of these annualized jobs would be associated with non-Tongass harvest under each alternative. Average annual total employment (direct, indirect, and induced) would range from 970 jobs under Alternative 1 to 3,829 jobs under Alternative 7. The potential effects on direct and total income are also summarized by alternative in Table 3.22-20.

The impact of the recent policy change (March 2007), referred to as the Limited Interstate Shipment Policy, on wood products-related employment at the Forest level will most likely be positive. The policy is expected to increase the likelihood that timber sales on the Tongass will have a positive appraisal and is expected to increase the utilization of timber harvested on the Tongass and improve the economics of timber sales by providing a market for smaller diameter and low grade material that cannot be processed profitably by sawmills in Southeast Alaska at present (Alexander et al. 2007).

Under Alternatives 1 and 2, only a portion of the NFS timber harvested would be processed in Southeast Alaska sawmills because there is a limited market for utility

[4]As noted above, the McDowell Group (2006b) have since adjusted their annual estimate for private and state lands to 60 to 63 MMBF.

logs and lower value sawlogs. The higher volume alternatives are, however, based on the assumption that as sale volumes increase and perceptions of risk decrease, the industry will develop in an integrated fashion, with different operations using materials that are inefficient or excess to one another's production needs. If this were to occur the percent of the harvest that would be processed locally would likely be higher than current levels (66 percent). As a result, the employment estimates presented in Table 3.22-20 should be viewed as minimum employment levels that likely underestimate the amount of sawmill (or other processing facility) employment that would occur at higher harvest levels.

Table 3.22-20
Projected Timber Industry Employment at Maximum Allowable Timber Harvest Levels (First Decade, Annual Average)

Total	**19.5**	**19.5**	**35.3**	**42.3**	**56.7**	**51.1**	**51.0**	**72.5**
Total Income (Direct, Indirect, Induced)[6]								
Logging	20.6	21.4	34.3	40.0	51.7	47.1	47.0	64.5
Sawmills	7.1	6.2	16.1	20.5	29.5	26.0	25.9	39.4
Total	**27.7**	**27.6**	**50.3**	**60.4**	**81.2**	**73.2**	**73.0**	**103.9**

[1] It is important to note that the NIC I levels by alternative that form the basis of these employment and income estimates are not projected harvest levels. Rather, they represent the maximum NIC I volumes that could be harvested under each alternative.
[2] Total Southeast Alaska harvest includes Tongass, private (Native corporation), and state harvests. Private and State harvests are assumed to remain constant at 109 MMBF under all alternatives (Brackley et al. 2006a).
[3] Logging and sawmill job/MMBF ratios, 2.31 jobs/MMBF and 3.31 jobs/MMBF, respectively, are based on 2000 to 2005 average levels of employment per MMBF of net sawlog volume harvested (Alexander 2007).
[4] Logging employment is calculated by multiplying total Southeast Alaska harvest (including non-Tongass harvest) by 2.31 jobs/MMBF. Note: these estimates are based on current industry structure and assumed behavior.
[5] Sawmill employment is calculated based on the estimated sawlog share of harvest on the Tongass (66 percent) (Alexander 2006). Non-Tongass harvest, with the exception of about 7 MMBF harvested from state lands, is assumed to be exported in unprocessed form. Note: these estimates are based on current industry structure and assumed behavior.
[6] Total employment and income multipliers are from the 1998 IMPLAN model (see Table 3.22-4). Note that the estimate of direct employment embedded in the IMPLAN number will not be the same as direct employment calculated using actual Southeast Alaska logging and sawmilling data. You cannot subtract the direct employment estimates from the total employment numbers to get indirect and induced employment.
[7] Direct income is estimated using the annual average wage for the Alaska Forestry and Logging ($42,257) and Wood Products Manufacturing ($31,690) sectors from 2001 to 2005 (Alexander 2007).

Wood Products and Timber Demand—Short-Term Effects

In order to provide a stable timber sale program and provide a continued flow of timber to regional timber processors, the Forest Service employs a "buffer stock" approach to timber sale planning. The resulting timber sale program is complex and requires that the Forest Service manage four "pools" of timber volume, commonly referred to as the "timber pipeline." These pools of timber volume include: volume under contract, NEPA-cleared volume, timber volume in preparation, and timber volume identified in the Forest Service's 5-year Plan. The "timber pipeline" and its constituent parts are discussed in more detail in the *Timber* section of this EIS.

Timber sales can take from 3 to 5 years to complete. Sales offered by the Forest Service vary in size to meet the needs of different purchasers and in preparation time as a function of the sale offering size. Uncertainty and delays may be introduced through appeals and litigation. The buffer stock approach and the variable length of the timber sale process generally make it difficult to draw a direct relationship between particular sales and regional timber demand. It is, however, apparent that under current conditions a reduction in the timber volume under contract (i.e., the volume included in timber sales that have been purchased, but not logged or only partially logged) would affect regional timber operators, with related effects to regional employment and income. The affected volumes could be replaced or substituted in part or fully, but this would take time and reductions in the volume under contract would have direct and relatively immediate effects upon the affected operators.

The following discussion addresses the potential effects of the alternatives on three key components of the "timber pipeline": volume under contract, NEPA-cleared volume (i.e., sales that have approved NEPA documents but have not yet been sold), and timber volume in preparation (i.e., proposed sales that are currently being evaluated under the NEPA process).

Volume Under Contract

As noted above, volume under contract refers to the volume included in timber sales that have been purchased, but not logged or only partially logged. Volume under contract is, therefore, essentially a measure of inventory that changes on a regular basis, increasing as timber is sold and added to the total and decreasing when sales are actually harvested. The following discussion illustrates the potential effects of the alternatives on volume under contract with reference to data from August 2006. It should be noted that while these data provide an indication of potential impacts, the actual impacts would depend on the volume that is under contract when the decision is implemented and whether potentially affected existing sales were cancelled as part of the decision.

The Forest Service had approximately 104 MMBF in uncut volume under contract in August 2006. The majority of this volume (92 percent) was located in Ranger Districts on the south end of the Forest, with the Ketchikan and Wrangell ranger districts accounting for 41 percent and 25 percent of the total, respectively. This volume was under contract with five purchasers, including Pacific Log and Lumber (41 percent of the total), Viking Lumber Company (25 percent), and Alcan Forest Products (23 percent). Note that the corresponding volume in July 2007 was 102 MMBF (USDA Forest Service 2007e).

Review of the proposed alternatives indicated that 52 percent of the volume under contract in August 2006 could be affected under Alternative 1, which would maintain all Inventoried Roadless Areas on the Tongass in a natural condition and not permit timber harvest in these areas. The volume currently under contract would not be affected under any of the other alternatives.

Existing volumes under contract likely represent the majority of the short-term timber supply for the affected purchasers and reductions in the existing volume under contract would be difficult to make up from other areas in the near future. Reductions in the volume under contract could, therefore, potentially affect both sawmill and logging employment. Using the logging and sawmill job/MMBF ratios employed for the preceding long-term effects analysis (2.31 jobs/MMBF and 3.31 jobs/MMBF, respectively) and assuming the entire volume would be harvested and approximately

50 percent of the total would be processed locally, the potentially affected volume of 54 MMBF would support approximately 214 job-years.

NEPA-Cleared Volume

The Forest Service had approximately 454 MMBF in the NEPA-cleared volume pool in August 2006. It should be noted that not all this volume is considered economic under current market conditions. Review of the proposed alternatives indicated that approximately 56 percent and 44 percent of this volume could be affected under Alternatives 1 and 2, respectively. These data are intended to illustrate the potential effects. As noted with respect to the volume under contract, actual impacts would depend on the NEPA-cleared volume when the decision is implemented. The NEPA-cleared volume in September 2007 was 309 MMBF (USDA Forest Service 2007f).

Timber Volume in Preparation

The third component of the timber supply is the timber volume in preparation. The Forest Service had approximately 536 MMBF in preparation in September 2006 spread across 17 separate projects. Under Alternative 1 approximately 56 percent of the proposed total would not be available for harvest. Alternatives 2 and 3 would each affect 7 percent of the proposed total. As noted above, these data are intended to illustrate the potential effects. Actual impacts would depend on the timber volume in preparation when the decision is implemented. The Forest Service had approximately 384 MMBF in preparation in September 2007 (USDA Forest Service 2007f).

Recreation and Tourism

The following analysis addresses recreation and tourism over the decade following implementation. Recreation supply is subject to cumulative impacts with the effects of timber harvest activities on recreation places accumulating over time and increasing impacts felt in later decades.

Supply

The general methodology for deriving projected levels of recreation and tourism employment is described in detail in the Affected Environment part of this section. Three types of recreation opportunity settings (ROS 1, ROS 2, and ROS 3) are used in the economic analysis. Timber harvest and other activities result in a reclassification of certain acres from one ROS group to another. Road construction, for example, will generally cause a given area to be reclassified as ROS 3 (Roaded Natural, Roaded Modified, and Rural). The availability for use of ROS 3 designations also depends on the connection between proposed road networks and ferry landings or local communities. Had these acres been classified as ROS 1 (or ROS 2) previously, the result would be a net reduction of ROS 1 (or ROS 2) and an increase in ROS 3. Depending on the relative demand for different ROS groups, the result could be an increase, a decrease, or no change in recreation and tourism activity. If, in the current example, demand for ROS 1 exceeds supply and ROS 3 settings are in surplus, then the net result would be a decrease in recreational activity. If, however, supply exceeds demand for both ROS classes, the net impact on recreation and tourism activity is assumed for the purposes of this analysis to be zero.

Each ROS group has a maximum capacity based on the type of experience expected within the setting. ROS 1 has the lowest capacity per acre because it provides primitive recreation opportunities that require that users not be within sight or sound of other parties. While ROS 2 has a higher capacity per acre than ROS 1, users in this setting expect to see only a few other parties during their experience. ROS 3 has the highest capacity and users in this setting may expect to interact frequently with others. Timber harvest activity could, therefore, result in an increase in recreation capacity measured in terms of RVDs, because areas classified as ROS 1 or ROS 2 would be converted to ROS 3.

Demand

Future demand for recreational activity on the Tongass National Forest was predicted using a linear projection of total RVDs (see Figure 3.22-7). Historical patterns of RVD use by ROS class were then used to predict future recreation and tourism demand by ROS class. Using this methodology, estimated demand for ROS 2 class RVDs (Semi-Primitive Motorized) exceeded estimated supply of ROS 2 settings in 1998. Differences in projected levels of recreation use between alternatives are small because ROS 2 is the only setting where demand exceeds supply in the first decade of this analysis and effects related to harvest activity have had little time to accumulate. As discussed in the Affected Environment section, the finding that demand exceeds supply is based on the supply of ROS 2 opportunities in specifically identified recreation places only and assumes there would be no change in the current availability of recreational settings. These assumptions do not accurately reflect underlying supply realities but are necessary to allow a quantitative comparison of the alternatives.

Consumption

Projected supply and consumption are presented in RVDs by alternative for the next decade in Table 3.22-21.

Table 3.22-21
Recreation/Tourism Supply, Demand, and Consumption (First Decade, Annual Average)

		Alternative						
	2015	**1**	**2**	**3**	**4**	**5**	**6**	**7**

ROS2	1,995	2,018	2,007	2,000	1,972	1,995	1,994	1,966
ROS3	993	993	993	993	993	993	993	993
Total	**4,092**	**4,115**	**4,104**	**4,097**	**4,069**	**4,092**	**4,091**	**4,064**

Employment and Income

Projected average annual recreation and tourism-related employment and income is presented by alternative in Table 3.22-22. Direct employment was calculated using a job/RVD ratio of 0.00074, which was developed for the 1997 Forest Plan Revision Final EIS (see the Affected Environment subsection of this section). The direct and total employment rows, and the corresponding rows under income, include both resident and nonresident Tongass-related recreation.

The rows that address nonresident recreation include nonresident Tongass-related employment, as well as an estimate for non-Tongass-related, nonresident recreation and tourism in Southeast Alaska. Nonresident recreational activities were assumed to account for 44 percent of direct employment. Direct nonresident employment also

Table 3.22-22
Recreation/Tourism Related Employment and Income (First Decade, Annual Average)

	Alternative							
	2015	**1**	**2**	**3**	**4**	**5**	**6**	**7**
	Employment (Jobs)							
	Resident and Nonresident Tongass-Related Recreation Employment							
Direct Employment[1]	3,028	3,045	3,037	3,032	3,011	3,028	3,027	3,007
Total Employment[2]	3,664	3,685	3,675	3,669	3,643	3,664	3,663	3,639
	Nonresident Tongass-Related and Non-Tongass-Related Employment							
Nonresident Recreation-Related Direct Employment[3]	4,319	4,327	4,323	4,321	4,312	4,319	4,319	4,310
Total Nonresident Recreation-Related Employment	5,226	5,235	5,231	5,228	5,217	5,226	5,226	5,215
	Income (Million 2005)							
	Resident and Nonresident Tongass-Related Recreation Income							
Direct Income[4]	53.9	54.2	54.1	54.0	53.6	53.9	53.9	53.5
Total Income[5]	71.2	71.6	71.4	71.3	70.8	71.2	71.1	70.7
	Nonresident Tongass-Related and Non-Tongass-Related Income							
Nonresident Recreation-Related Direct Income	76.9	77.0	77.0	76.9	76.8	76.9	76.9	76.7
Total Nonresident Recreation-Related Income	101.5	101.7	101.6	101.5	101.3	101.5	101.5	101.3

[1] Direct employment was estimated using a job/RVD ratio of 0.00074 (average annual) and includes both resident and nonresident Tongass-related employment.
[2] Total (direct, indirect, and induced) employment estimates were calculated using a 1.21 employment multiplier (see Table 3.22-4).
[3] Nonresident recreation-related employment was calculated using the assumption that 44 percent of ROS 1, 2, and 3 RVDs are consumed by nonresidents. This estimate also includes non-Tongass-related recreation and tourism employment, which is assumed to remain constant across all of the alternatives. The non-Tongass employment was estimated based on total direct employment in the leisure and hospitality sector in 2005. This component was estimated to increase by 20 percent between 2005 and 2015, which is equivalent to less than half the increase in growth of Juneau cruise ship passenger volumes between 2000 and 2005.
[4] Direct income is estimated based on the 2004 statewide average annual salary for the Leisure and Hospitality sector ($17,220) adjusted for inflation to $17,803 in 2005 dollars and includes both resident and nonresident Tongass-related incomet.
[5] Total (direct, indirect, and induced) income estimates were calculated using a 1.32 income multiplier (see Table 3.22-4).

includes an estimate of the jobs associated with non-Tongass recreation and tourism activities pursued by nonresidents. This category is intended to represent the jobs associated with recreation and tourism activities that do not physically take place on the Tongass National Forest. These types of activities include viewing scenery from cruise ships (see Table 3.22-22, note 3).

The distinction between resident- and nonresident-related employment is important because jobs generated by nonresident expenditures on goods and services are considered comparable to an export industry that brings new money into the region. Expenditures by local residents, on the other hand, represent a recirculation of money that is already present in the regional economy and are, therefore, not typically identified as “new” money. However, if residents are substituting local recreation for non-local recreation then their money can be considered to be money that would otherwise not be present in the local economy. The extent to which this is the case can only be identified by surveying local residents and asking detailed questions about their substitution decisions with respect to Tongass-based recreation (Rudzitis and Johnson 2000). This type of information is not available for the Tongass and, more importantly, inclusion of resident recreation-related employment in the final summary table would have little effect on these results, which show very little difference across the alternatives under either scenario.

Mining

While it is not possible to project the potential effects of the proposed alternatives on mining employment or income, allocating areas to non-development or development LUDs could affect mining activities in the future. None of the alternatives would allocate areas to Recommended Wilderness or LUD II. However, alternatives that would increase the roaded portion of the Forest, such as Alternatives 7 and 4, may facilitate mining exploration and development more that those that retain Roadless areas (especially Alternatives 1, 2, and 3). Alternatives 5 and 6 would be intermediate, representing little or no change from allocations under the current Forest Plan. The effect on future mining employment and income would depend on whether the potentially affected locatable deposits are economically viable in the future.

Transportation and Utilities

Residents of Southeast Alaska are dependent on air and water transportation for travel between most communities, rather than roads or rail. There are limited road connections between the region and the continental road system and between communities. Several possibilities exist for State Highways that could connect some Southeast Alaska communities to the continental road system, as well as possibilities for new internal corridors.

The State of Alaska has proposed corridors for transmission lines and/or undersea cables to link many Southeast Alaska communities to British Columbia. An intertie corridor, connecting the Swan Lake project (near Carroll Inlet) with the Tyee project (on the Bradfield Canal) has been permitted and with construction initiated in 2002. A number of other potential interties could include powerlines between a number of different communities, including some of the smaller and more remote communities, such as Kake and Meyers Chuck.

None of the alternatives would affect regional transportation opportunities or power transmission line opportunities. This is discussed in further detail in the *Transportation and Utilities* section of this document.

Salmon Harvesting and Processing

There is not expected to be any significant change to the commercial fishing or fish processing industries over the next decade as a result of national forest activities. As noted in the Affected Environment discussion, much of the future of the fishing industry in Southeast Alaska is expected to depend on occurrences outside of the Tongass National Forest such as hatchery production, off-shore harvest levels and changes in ocean conditions. In addition, a large segment of the commercial fishing industry operates under a limited entry harvest system. New permit holders are not usually added to the market during high fish harvest years, nor are they removed during periods of low harvest. The result in either case is the same number of commercial fishers catching either more or less fish.

The 1997 Final EIS noted that the amount of acreage of timber harvest was at most less than 20,000 acres per year, representing approximately 0.5 percent of the total remaining productive old growth (or 5 percent over the next decade) and less than 0.02 percent of the entire Forest. That EIS concluded that this was not expected to result in a significant change to commercial fishing employment. Under the proposed alternatives, the estimated harvest would range from less than 2,000 to approximately 16,000 acres per year (see Table 3.13-9 in the *Timber* section). This level of harvest, which is under the maximum proposed in the 1997 EIS, in conjunction with the Riparian Management Standards and Guidelines established in the current Forest Plan and included in the updated Forest Plan prepared for the action alternatives (Volume II in this EIS), is not expected to have a significant effect on commercial fisheries employment over the next 10 years.

Natural Amenities and Quality of Life

As discussed in the Affected Environment portion of this section, natural amenities and local quality of life have increasingly been recognized as important factors that serve to attract and retain residents. It is, however, very difficult to determine the effect of the different alternatives on local amenities and, further, on the economic activity that these amenities are believed to indirectly generate. In most cases and localities the impacts of the action alternatives relative to the No-Action Alternative on amenities are not expected to be significant enough in themselves to result in measurable changes in economic activity.

This conclusion is based on the Forest Plan standards and guidelines that are designed to protect and/or mitigate negative effects to natural resources on the Tongass, as well as the relatively small proportion of the Forest that would be disturbed under any of the proposed alternatives. The importance of the standards and guidelines are discussed with respect to quality of life and other difficult to quantify values below in the part of this Economic Efficiency analysis that discusses Ecosystem Services. Potential harvest activities under the proposed alternatives would affect a relatively small proportion of the Tongass and would be unlikely to affect the predominantly wild and undeveloped nature of the region and the role it presently plays in attracting visitors and residents.

Summary of Impacts

Projected annual average employment and income levels are summarized for the next 10 years in Table 3.22-23. In terms of direct employment in the wood products and recreation and tourism industries, the alternatives range from 4,820 jobs under Alternative 1 to 6,231 jobs under Alternative 7 (Table 3.22-23). Most of the difference between these two values (1,411 jobs) is caused by differences in timber-related employment. Recreation and tourism employment shows much less variation across the alternatives, with a difference between high and low employment levels of less than 20 direct jobs. Direct earnings follow a similar pattern, as do total employment and earnings.

The employment and income estimates for the wood products sector assume the entire NIC I volume projected for each alternative for the first decade following implementation would be harvested. This outcome is dependent on the scenarios developed for each alternative, which assume for the more timber-intensive alternatives that as stable volumes get higher, the industry will develop in an integrated fashion. Recreation and tourism employment and income estimates are for nonresident, recreation and tourism activity only.

Potential direct employment effects are displayed in Table 3.22-24, which shows the projected change in employment by sector as a percent of current totals. Projected recreation and tourism employment is expected to increase by approximately 20 percent from 2005 levels under all of the alternatives. The majority of this projected increase is due to the projected change in non-Tongass, recreation and tourism-related employment, which does not vary by alternative in this analysis. Projected changes in wood products employment from 2005 levels range from a decrease of approximately 1 percent under Alternative 1 to a 285 percent increase under Alternative 7. These increases are relatively large because they assume that the entire NIC I component of the projected ASQ would be harvested under each alternative. This outcome is dependent on multiple factors beyond the Forest Service’s control, as discussed in the Wood Products, Long-Term Effects section.

None of the alternatives are expected to affect regional transportation or power transmission line development opportunities.

Economic Efficiency Analysis

Introduction

The Present Net Value of a given alternative is the discounted sum of all benefits minus the discounted sum of all costs associated with that

The 1982 planning regulations (36 CFR 219) require that land and resource management plans for National Forest System (NFS) lands "provide for multiple use and sustained yield of goods and services from the NFS in a way that maximizes long term net public benefits in an environmentally sound manner" [36 CFR 219.1 (a)]. These regulations define the term net public benefits as "the overall long-term value to the nation of all outputs and positive effects (benefits) less all associated inputs and negative effects (costs) whether they can be quantitatively valued or not." The definition continues: "(n)et public benefits are measured by both quantitative and qualitative criteria rather than a single measure or index" (36 CFR 219.3).

Net public benefits are evaluated in this EIS through an economic efficiency analysis, which is one type of measure the Forest Service Manual (FSM) encourages the economic and social analyses for Forest Service resource plans to provide (FSM 1970.61). Economic efficiency analysis seeks to measure the costs and benefits to society associated with each alternative and summarize them in the form of a present net value (PNV). PNV figures are calculated by subtracting costs from benefits to yield a net value. Future values (i.e., costs and benefits incurred and received in the future) are discounted using an appropriate discount rate to obtain a present value. The PNV of a given alternative is the discounted sum of all benefits minus the discounted sum of all costs associated with that alternative. Following Forest Service standard procedures, a 4 percent real discount rate is used in the following analysis.

The 1982 planning regulations direct that analysis of the estimated effects of alternatives include, among other things "the expected real-dollar value (discounted when appropriate) of all outputs attributable to each alternative to the extent that monetary values can be assigned to nonmarket goods and services, using quantitative and qualitative criteria when monetary values may not reasonably be assigned" [36 CFR 219.12 (g) (3) (ii)]. Potential forest management outputs that could be affected by the various Forest Plan alternatives include those generated from commodity production, the value experienced by recreationists and other users of the Forest, the "non-use" values held by those who value the existence of the Forest resource even if they do not use it, and the value of various services (ecosystem services) provided by the Forest, such as water resource enhancement, that are not directly traded in any economic market place.

Economists face several challenges when they attempt to summarize the values of various goods and services produced by Forest management. First, while economists generally follow a typology of values that includes both use and non-use values there are concerns about the tendency of many economists to use monetary values for both types. Most economists acknowledge that monetary measures while convenient and easily communicated, are weak approximations of social values. Difficulties exist in trying to assign values to beliefs (sometimes called held values) and other forms of social values. Second, since no markets exist for many ecosystem goods and services economists have to rely on non market valuation techniques such as willingness-to-pay (WTP) approaches. The mix of market and non-market values poses theoretical problems by mixing both marginal and average values depending on the processes used to establish the values. Third, any estimate of value is temporally specific, and this complicates summation processes and relative comparisons.

Comments on the Draft EIS

Comments on the economic efficiency analysis presented in the Draft EIS were concerned with two main aspects of the analysis: 1) the absence of non-market values, other than recreation and tourism, and 2) the misleading comparison of actual timber costs and revenues with estimated recreation and tourism consumer surplus values, which were estimated using WTP values. These issues are briefly summarized below and discussed in more detail in Appendix H, Comments and Responses.

Non-Market Values

The Draft EIS provided a brief overview of comments received on the 2002 Draft SEIS that expressed concern that the economic efficiency analysis presented in that document did not assign monetary values to all the goods and services provided by the Tongass National Forest. Several organizations commenting on the 2006 Draft EIS made the same or very similar comments on the Draft EIS analysis. Concerns were expressed that the analysis presented in the Draft EIS did not assign monetary values to uses, such as commercial fishing and subsistence, or quantify potential effects to non-use values, ecosystem services, and quality of life or off-site benefits in monetary terms. Several comments argued that by failing to assign monetary values to non-market goods and services—such as fish and wildlife habitat, water purification and regulation, carbon sequestration, genetic material, long-term forest productivity, and quality of life—the Forest Service has essentially assigned these goods and services a value of zero and discounted them relative to commodity production.

Given the complexity of forest ecosystems and the elusive nature of many of the values associated with them, accurately accounting for all of these values in a single PNV measure is not feasible at this time. This, as explained in the Draft EIS, is by no means intended to imply that the Forest Service believes the other types of values mentioned above are unimportant. Many of the other sections in this document, in fact, present substantial amounts of information and analysis relative to the resources supporting these other values. Decision-makers will consider the economic values presented in this section within the context of the information presented elsewhere in this document, much of which cannot readily be translated into economic terms.

Misleading Comparison

Others providing comments on the Draft EIS expressed concern about the analysis summarized in Table 3.22-29 of the Draft EIS, which they believed provided a misleading comparison between timber and recreation and tourism. The table presented a PNV that consisted of projected timber revenues and costs to the Forest Service and recreation and tourism consumer surplus benefits that were estimated based on WTP estimates. Concerns were expressed about the overall validity of WTP methodologies and comments suggested that including consumer surplus estimates to value recreation and projected revenues and costs for timber resulted in a misleading comparison between these sectors. Others were concerned that the analysis was unbalanced because it did not include Forest Service costs for recreation, only user benefits.

Revised Economic Efficiency Analysis

The following analysis has been revised to include estimated Tongass National Forest costs and revenues for the NFS budget items based on costs and revenues from 2005 and 2006. In addition, we have separated the estimated costs and revenues from the recreation and tourism consumer surplus to emphasize the difference between these types of measures.

The following analysis assumes that any alternative would be fully implemented in the first year of the planning period, and future values were discounted at four percent. Table 3.22-25 displays these cost and benefits followed by more detailed explanations of their derivation. The potential effects of the proposed alternatives on salmon harvesting and processing, subsistence, and non-use and ecosystem service values are assessed qualitatively.

Timber

The timber benefits presented in Table 3.22-25 are the present value of expected Forest Service revenues from the timber sale program. Future timber sale revenues were estimated for the 160-year planning period using projected harvest volumes for each alternative. These volumes were calculated based on the estimated NIC I volumes by alternative. The analysis in the Draft EIS used an average rate of $11.69/MBF, which was the average value per MBF harvested on the Tongass in 2005/2006. We have revised this analysis and the estimated timber benefits identified in Table 3.22-25 are instead based on the minimum prices or “base rates” established for timber species on the Tongass National Forest. The base rate is the minimum value that must be bid for timber to be sold or cut.

The timber benefit estimates presented in Table 3.22-25 were calculated by developing an average base rate value per MBF based on the average timber sale composition (by species) and current base rates (see Table 3.22-25, note 1). The resulting estimates are, therefore, the minimum revenues or benefits that would be generated over the period of analysis (160 years). These estimates are also based on the assumption that all the NIC I volume identified under each alternative would sell and this may not necessarily be the case.

Table 3.22-25
Economic Efficiency Analysis (million 2006$)

	Alternative						
	1	2	3	4	5	6	7
Benefits							
Revenues							
Timber Revenue[1]	9	26	34	55	44	44	68
Recreation Revenue[2]	54	54	54	54	54	54	54
Land Use Revenue[3]	7	7	7	7	7	7	7
Power[3]	1	1	1	1	1	1	1
Minerals[3]	1	1	1	1	1	1	1
Consumer Surplus							
Recreation/Tourism Consumer Surplus[4]	7,637	7,640	7,643	7,610	7,645	7,645	7,599
Costs[5]							
Timber Variable Costs[6]	128	376	489	787	625	620	967
Inventory & Monitoring[7]	67	67	67	67	67	67	67
Land Management[8]	75	75	75	75	75	75	75
Minerals and Geology[7]	32	32	32	32	32	32	32
Recreation/ Heritage/ Wilderness Mgmt[7]	111	111	111	111	111	111	111
Vegetation, Watershed, Wildlife & Fisheries Habitat[8]	184	184	184	184	184	184	184
Present Net Value	**7,112**	**6,884**	**6,782**	**6,472**	**6,657**	**6,662**	**6,294**

Note: Cost and benefit streams extended over a 160-year analysis period and discounted at 4% per year.

[1] Based on the average base rate per MBF using the average timber sale composition and the following current base rates: Sitka Spruce—$12, Western Hemlock—$2, Western Red Cedar—$12, Alaskan Yellow Cedar—$20.

[2] Recreation revenue was estimated based on the average recreation revenues received in 2005 and 2006. Revenue categories included in this total are: Recreation, Recreation User Fees, Recreation Fee Collection, and Recreation Site Fees (USDA Forest Service 2006d, 2007g). These revenues are assumed for the purposes of this analysis to remain at current levels and constant across all alternatives.

[3] Land use, power, and minerals revenues were estimated based on average revenues received in 2005 and 2006. These revenues are assumed for the purposes of this analysis to remain at current levels and constant across all alternatives.

[4] Unlike timber or minerals, recreation and tourism is not directly traded in the market place and recreationists on the Tongass generally pay for only a small portion of the total benefits they receive from the Forest. In other words, the recreation revenue category above does not capture the full value of the experience to recreationists. Economists have developed techniques to try and estimate the amount that recreationists would be willing-to-pay for a Recreation experience above and beyond what they actually pay. This is discussed further in the following section under recreation. It is important to understand that the recreation/tourism consumer surplus values shown here assign a monetary value to the share of the recreation good that is not traded in the market place and, as a result, are not directly comparable with actual revenues paid to the Forest Service.

[5] The following cost items include the major NFS cost items based on actual costs for 2005 and 2006 (USDA Forest Service 2006d, 2007g). They do not include other costs that are classified under Capital Improvement, Fire, Miscellaneous Funds, or Other. The cost categories included in this summary were approximately $31,000 in 2005 and 2006, accounting for approximately 37 percent and 44 percent of total costs in 2005 and 2006, respectively. This is discussed further in the following section under Management Costs.

[6] Based on per MBF planning and support charges: $41 for NEPA preparation; $23 for sale preparation; $9 for sale administration; and $28 for engineering support.

[7] Inventory & Monitoring, Minerals and Geology, and Recreation/ Heritage/ Wilderness Mgmt costs were estimated based on average costs in 2005 and 2006. These costs are assumed for the purposes of this analysis to remain at current levels and constant across all alternatives.

[8] Land Management and Vegetation, Watershed, Wildlife & Fisheries Habitat costs were estimated based on average costs in 2005 and 2006. Cost categories included in these totals are Land Management Planning and Land Ownership Management (Land Management) and Vegetation & Watershed Management and Wildlife & Fisheries Habitat Mgmt (Vegetation, Watershed, Wildlife & Fisheries Habitat). These costs are assumed for the purposes of this analysis to remain at current levels and constant across all alternatives.

The Spectrum model analysis—used to identify the ASQ for each alternative—suggests that under current market conditions stumpage values for some stands would be negative (see Appendix B for more detail on this model). In other words, the estimated costs of harvesting and transporting the timber exceed the current value of the timber at the mill (the pond log value) and, as a result, volume from these stands would be unlikely to sell. While the Spectrum model analysis suggests that there would be sufficient economic timber to provide projected NIC I volumes (should there be demand) in the short-term under current market conditions, market prices would need to improve over the long-term for stands that would be potentially harvested in later decades to sell.

Timber variable costs are also presented for each alternative in Table 3.22-25. These costs are estimated based on a flat rate of $101/MBF and assume the identified NIC I volumes for each alternative would be sold. This flat rate includes NEPA preparation ($41/MBF), sale preparation ($23/MBF), sale administration ($9/MBF), and engineering support ($28/MBF), and includes timber sale-related road construction costs, among others. This average cost per MBF ($101/MBF) exceeds the average base rate value per MBF ($7.12/MBF) used to estimate timber benefits to the government for this analysis. As noted above, the average base rate is the minimum value that must be bid for a timber sale to go forward. The average value for 2005/2006 was $11.69 per MBF. The 2003 SEIS identified an average value of $36.17 per MBF harvested on the Tongass from 1997 to 2001 (USDA Forest Service 2003b). Recent sales on Alaska State lands have generated an average return of $49.54 per MBF for sales totaling 54 MMBF (Slenkamp 2007).

Industry revenues and profits are omitted from the calculation. This is because efficiency analysis commonly assumes perfect competition in the private sector. This implies, in turn, that competing purchasers of federal timber will bid up the price of stumpage to the point where all economic profits (i.e., profits over and above a competitive rate of return to capital) are dissipated.

It is important to note that the PNV calculation for timber does not assign monetary values to perceived local benefits associated with timber-related employment and salaries and related economic activity, as well as other perceived benefits associated with capital investment in roads and log transfer facilities. Employment and income are addressed in the preceding economic impact assessment.

As previously noted, it is also important to recognize that the NIC I component is not a future sale level projection or target. Rather, it represents the maximum volume that could be harvested with normal logging systems.

Recreation and Tourism

The analysis presented in Table 3.22-25 provides two sets of values for recreation benefits: 1) recreation revenues and costs paid to the Forest Service, and 2) recreation and tourism benefits to the consumer, identified in Table 3.22-25 as recreation and tourism consumer surplus.

Recreation Revenues and Costs

Recreation revenues and costs were estimated based on the average receipts paid to the Forest Service in 2005 and 2006. The values used for the analysis were based on the average values for those two years. Forest Service revenue categories included in this total are the general recreation category, recreation user fees, recreation fee collection, and recreation site fees. Recreation cost categories are shown in Table 3.22-25 as part of the Recreation/Heritage/Wilderness budget line item. This budget item was about $4.3 million in 2005 and $4.6 million in 2006. In addition to these budget item costs, other recreation-related costs incurred in 2005 and/or 2006 and not included in this cost category are trail improvement and maintenance costs, outfitter/guide program management costs, recreation site maintenance and operation, and recreation fee collection costs. These costs are included elsewhere in the Forest Service's accounting system (e.g., capital improvement, miscellaneous funds, and other) and varied substantially between 2005 and 2006, the years used to establish the baseline used here.

Recreation revenues and costs are included in this analysis to address concerns about misleading comparisons and also provide an indication of the relative management costs and revenues associated with different Forest resources. Budget figures from 2006 are also summarized in Table 3.22-28.

Recreation and Tourism Consumer Surplus

Unlike timber, recreation and tourism is, for the most part, not directly traded in the market place. Recreational users of the Tongass National Forest generally pay for only a small proportion of the total benefits they receive from the Forest. Consumer surplus, or willingness-to-pay, is the value of a recreation activity beyond what must be paid to enjoy it. Total economic use value is the cost to participate plus consumer surplus. This type of approach is very different to those used to estimate the other benefits and costs summarized in Table 3.22-25.

The consumer surplus estimates presented in Table 3.22-25 are derived from 1988 survey data. For general recreational activity, this figure is estimated at $33.00 (2005$) per RVD, and for recreational fishing the estimate is approximately $1,025.27 per RVD (2005$). Using the proportion of 1994 total RVDs comprised by recreational fishing use, a weighted average of $69.13 per RVD was derived. This figure represents the average amount a Tongass National Forest recreational user would be willing to pay for a day's recreation over and above expenses already incurred. These net willingness-to-pay figures are from the 1997 Forest Plan Revision Final EIS adjusted for inflation (USDA Forest Service 1997a, p. 3-503).

Future recreation and tourism use on the Tongass was estimated using techniques described in the Affected Environment portion of this section and further detailed in the recreation and tourism impact analysis presented above. Projected future value was derived by multiplying total RVD use by the average net WTP estimate of $69.13. These values were then discounted using the standard 4 percent rate, and the resulting estimates are shown in the second row of Table 3.22-25. Recreation and tourism consumer surplus estimates are much higher than the other benefits and costs addressed in Table 3.22-25, but are relatively constant across the alternatives. The finding that these values are relatively constant across alternatives is consistent with the expected outcome of the Forest Plan, which seeks to protect high value and high use recreation areas under all alternatives, while the high values reflect the wide range of unique recreation opportunities on the Tongass National Forest.

There is the potential for substantial error in these value estimates, and decision makers and the public should avoid a mistaken sense of precision when considering them. Various aspects of recreation and tourism-related value, for example, were impossible to measure or estimate for this analysis. All RVDs have been treated as equivalent, but it is likely that net WTP varies for different recreation experiences and associated ROS classes. Likewise, the net WTP value for a given recreation experience will vary according to a host of factors which may be impacted differently under the different alternatives. By using a constant dollar per RVD estimate, this takes only quantity into account and ignores quality. This quality can take many forms, but must include aesthetic considerations, personal attachments (in the case of local residents who habitually frequent the same "favorite places"), availability of fish and game, the effects of crowding, and ease of access. Moreover, these quality considerations will extend beyond recreational use directly occurring on the Tongass National Forest to include cruise ship passengers and others who have come to the region to mainly experience its beauty and wild character.

Management Costs

The Forest Service incurs various costs in the management of the national forests. Some of these can be directly attributed to a specific management activity or objective, but many others cannot. Likewise, some costs will vary depending upon specific activities stipulated in the Forest Plan. Others, however, are essentially fixed operating costs that will likely not vary for different alternatives.

The timber variable costs presented in Table 3.22-25 are based on average costs (dollars per MBF) resulting from planning and administration activities in conjunction with recent timber sale projects on the Tongass National Forest. Costs are also presented for the following NFS program costs: Inventory and Monitoring; Minerals and Geology; Recreation, Heritage, and Wilderness Management; Land Management Planning and Land Ownership Management; Vegetation and Watershed Management; and Wildlife and Fisheries Habitat Management. The costs assigned to these categories are estimated based on the average 2005/2006 costs for these cost categories and are assumed to remain constant across all alternatives. The choice of alternatives would undoubtedly affect these fixed operating costs, but we are unable to predict how they would be affected.

Additional costs may be imposed on organizations or individuals outside of the Forest Service. These costs are commonly termed “negative externalities” by economists. The current analysis makes no attempt to assign dollar values for the negative externalities that may be associated with the alternatives. Instead, the Forest Service addresses these by providing as much information as possible about the physical and ecological impacts of the alternatives, and using this information in the public participation process associated with the Plan.

Salmon Harvesting and Processing

With the exception of Alternatives 4 and 7, the effects of the alternatives on fish resources are expected to be at or below the level predicted for Alternative 11 in the 1997 Forest Plan Revision Final EIS (USDA Forest Service 1997a, pages 3-46 through 3-73). Alternative 4 is expected to have similar effects to Alternative 6 in the 1997 Forest Plan Final EIS. The effects of Alternative 7 are expected to be similar but less than those projected under Alternative 2 in the 1997 Forest Plan Final EIS. Effects are expected to be lower than those projected under the 1997 Alternative 2 because Alternative 7 includes improved riparian protections. The analysis of effects on fish habitat included in the 1997 Forest Plan Final EIS is incorporated into this EIS by reference. This is also the case with the commercial fishing portion of the economic efficiency analysis presented in the 1997 Final EIS (page 3-504). This section of the 1997 Final EIS explains why PNV estimates were not prepared for the economic efficiency analysis presented in the Final EIS and these reasons also apply here. In addition, there has been a reduction in commercial harvest dependence on natural fish production from the Tongass in recent years.

The absence of quantified salmon harvesting and processing benefits in Table 3.22-25 should not be taken as an indication that this resource is not valued or that current and future management decisions are made without careful consideration of the potential impacts to these values. Potential impacts to fish are discussed in the *Fish* section of this EIS.

Mining

Estimates of mining PNV are also omitted from this analysis because it is not possible to quantify the potential effects of the alternatives on future mining activities.

Subsistence

Subsistence activities have significant economic, as well as cultural and spiritual value for many Southeast Alaska residents. However, there are a number of difficulties involved in trying to quantify these values in monetary terms. A 2001 study that attempted to quantify the economic importance of Alaska’s ecosystems used three different standard methods to estimate the statewide net economic benefits associated with subsistence (Colt 2001). This study concluded: “(i)n summary, it remains quite difficult to measure the net economic value of subsistence in economic terms. Using standard techniques, one can come up with estimates that range from zero (using a $4.00/lb replacement value less the cost of cash and labor input) to more than $1.7 billion (upper bound on net willingness to accept compensation for lost subsistence opportunities)” (Colt 2001; 37). Assigning an accurate economic value to subsistence is one significant problem in trying to calculate a PNV for subsistence. A second major problem involves quantifying the potential effects of the alternatives in terms of pounds of subsistence harvest foregone. This type of information is not available, as discussed in the *Subsistence* section of this document.

It is important to recognize that while it is not possible to assign subsistence a net economic value for the economic efficiency analysis, this does not mean that the potential effects of the alternatives on subsistence are not important. These potential effects are addressed programmatically in the *Subsistence* section of this document. They are also discussed on a community basis in the *Subregional Overview and Communities* section. The analysis presented in the *Subsistence* section assesses the potential effects of the alternatives in terms of abundance and distribution, access, and competition.

Non-use Values and Ecosystem Services

This section discusses non-use and ecosystem service values. Definitions of ecosystem services can be broad, including both use and non-use values. The following discussion uses a more narrow definition that applies to the group of services that is sometimes referred to as "life-support services." This definition excludes non-use and quality of life values, which are discussed separately below, as well as recreation use.

Non-use Values

Non-use values represent the value that individuals assign to a resource independent of their use of that resource. Non-use values include existence, option, and bequest values.

Economists have argued that recreation use represents only a portion of the economic value of natural areas. There are also non-use values associated with natural areas. Non-use values represent the value that individuals assign to a resource independent of their use of that resource. These types of values, which include existence, option, and bequest values, are usually measured via surveys that ask people how much they would be willing to pay to preserve a particular area. These values represent the value that individuals obtain from knowing that an area or resource exists, knowing that it would be available to visit in the future should they choose to do so, and knowing that it would be left for future generations to inherit.

While the non-use values associated with the Tongass National Forest as a whole are no doubt considerable, they are extremely difficult to accurately measure, particularly on a per acre basis. The results from surveys in other areas do provide some insight to potential non-use values that might be associated with the proposed alternatives. The findings of a number of recent studies are summarized in Table 3.22-26. These studies attempt to quantify the non-use values associated with wilderness and other types of natural areas in Alaska and other areas. WTP values are typically calculated on a per household basis and then expanded to a broader population. A critical issue here becomes identifying the extent of the survey area. Summing these types of values per household across large areas generates very high values. This issue is evident in the different geographical extent of the areas surveyed in the studies summarized in Table 3.22-26.

Examining the results of two of the studies summarized in Table 3.22-26 (Walsh et al. 1984 and Pope and Jones 1990), Loomis (2000) noted two trends that are relevant to this discussion. First, WTP per household increases with an increase in the number of acres proposed for wilderness protection, but at a decreasing rate. Second, existence, option, and bequest values in both cases represented about half the total value of wilderness. There are no new wilderness areas proposed under any of the alternatives, but these findings may also apply to areas preserved in a natural condition.

The results of the studies summarized in Table 3.22-26 suggest that the non-use values associated with maintaining areas on the Tongass in a natural condition are likely to be high, especially given the national importance of the Tongass. These values would likely increase with the number of acres, but at a lower rate. In terms of the proposed alternatives, the value per household is likely to be highest for Alternatives 1, 2, 3, 5 and 6, 4, and 7 in that order.

Table 3.22-26
Summary of Willingness-to-Pay Estimates of Existence Values

Author (Date)	Study Location	Description of Resource	Description of Commodity	Annual Willingness-to-Pay (2000$)[1]
Carson et al. 1992	Alaska: Prince William Sound	Prince William Sound coast and waters	WTP for spill prevention plan	$3.13 per U.S. household per year ($32.31 one-time)
Goldsmith and Hill 1998	Alaska: Bristol Bay Wildlife Refuges	13.2-million-acre wildlife refuges made up of three separate refuges	WTP for preserving wildlife habitat in Bristol Bay.	$26.05 to $52.11 per household U.S.
Walsh, et al. 1984	Colorado	1.2-million-acre designated wilderness area (2% of total state acreage) made up of 13 separate areas.	WTP to preserve existing wilderness areas in Colorado -- 1.2 million acres -- 10 million acres	 $23.07 per Colorado household $52.75 (1984$) per Colorado household
Reid et al. 1993	British Columbia	Current Wilderness in British Columbia.	WTP for doubling wilderness in British Columbia WTP for tripling wilderness in British Columbia	$11.80 per B.C. household ($118.02 one-time) $15.02 per B.C. household ($150.21 one-time)
Pope and Jones 1990	Utah	Bureau of Land Management land (BLM)	WTP for designation of BLM land in Utah million acres as wilderness. --2.7 million acres --16.2 million acres	 $69.50 per household $121.49 per household
Loomis 2000[2]	Western U.S outside Alaska	National Forest Roadless areas in Western U.S.	WTP to preserve roadless lands in the west	$6.72 per acre

[1] Values were adjusted to 2000 dollars using the Anchorage CPI for Alaska values and the U.S. CPI for all other areas.
[2] Estimated by Loomis using benefit-transfer approach from Walsh et al. (1984) and Pope and Jones (1990).
Sources: Colt 2001; Loomis 2000.

The summary of recent studies presented in Table 3.22-26 is meant to provide some indication of the results of other studies, only. While there is a general consensus that non-use values of this type exist and federal policy includes approval of such techniques, the methodologies for measuring the size of these values are both controversial and difficult to apply in a consistent fashion.

A recent study prepared by The Wilderness Society (Phillips and Silverman 2007), for example, used the values from the three of the studies shown in Table 3.22-25 (Carson et al., Goldsmith and Hill, and Loomis) to estimate annual passive use values of “wildlands” on the Tongass and Chugach National Forests that ranged from $6.8 million to $387.9 million. They then divided the difference to get an average annual passive value of $196.2 million. This analysis suggests that there is a passive use value associated with the Tongass National Forest, but the wide possible range identified for this value (with the high estimate [$387.9 million] 57 times as large as the low estimate [$6.8 million]) underlines the difficulty in estimating this type of value using a benefit transfer approach. This study is discussed in more detail in Appendix H.

Ecosystem Services

Ecosystem services are those services and benefits provided by healthy ecosystems. Definitions of ecosystem services can be broad, including both use and non-use values. A number of different definitions and groupings have been identified (Colt 2001; Costanza et al. 1997; Krieger 2001; Morton 2000). These include the typology developed by the Millennium Ecosystem Assessment (2005), which is featured on the Forest Service's Ecosystem Services web site (http://www.fs.fed.us/ecosystemservices/) and identifies four general categories of ecosystem services: provisioning, regulating, cultural, and supporting. This typology is also highlighted in Chapter 2 of this EIS. The Forest Service's Pacific Northwest Research Station recently issued a technical report that attempts to define an economics research program to describe and evaluate ecosystem services (Kline 2006).

Some definitions of ecosystem services include consumptive uses—such as logging, fishing, and hunting—that can be considered market goods, as well as non-use or passive use values. The values associated with these types of market goods and non-use values are discussed in the preceding sections. Other types of ecosystem services provide what might be considered long-term life support benefits to society as a whole. Examples of these types of benefits that pertain to forests include watershed services, soil stabilization and erosion control, improved air quality, climate regulation and carbon sequestration, and biological diversity (Krieger 2001).

Some economists have expressed concerns that ecosystem service values are not adequately considered in decision-making processes because they are not valued on a par with goods and services that are traded in commercial markets. A number of methods have been used to assign monetary values to these types of services. These methods include travel cost, hedonic pricing, and defensive expenditure approaches that use observed behavior to estimate values, as well as contingent valuation approaches that ask people what they would be willing to pay for an ecosystem service.

Costanza et al. (1997) estimated the total value of the services provided by the world's ecosystems ranges from $16 trillion to $54 trillion per year, with an average value of $33 trillion. Costanza et al.'s estimate involved the review and synthesis of a wide variety of existing studies and included estimates of recreation and cultural values, as well as more life-support-related services. Many of the studies used in their synthesis were based directly or indirectly on estimates of WTP. Colt (2001) applied Costanza et al.'s values to Alaska and estimated that the ecosystem values associated with the state's lands and waters ranged from $1.2 billion to $1.6 billion. Colt's estimate only included the components of Costanza et al.'s analysis that he considered to relate directly to life support services.

Phillips and Silverman (2007) applied the global values adopted by Colt (2001) to the Tongass National Forest and estimated that the annual ecosystem value of 15.7 million acres of the Tongass is $293.7 million. This analysis involved applying dollar per acre values for various ecosystem services, such as gas regulation, climate regulation, disturbance regulation, soil formation, and nutrient cycling, to five different forest biomes. Colt (2001, 42) notes that while the Costanza et al. estimates that form the basis of this analysis represent an important first step, they are "extremely primitive." Colt (2001, 43-44) also noted two obvious sources of bias with his analysis, which also apply to Phillips and Silverman's (2007) analysis. First, the average values per acre estimated by Costanza et al. and applied here are global averages derived from studies of population places and may have limited applicability to Alaska. Second, the data Colt adopted from Costanza et al., which Phillips and Silverman also use, does not address all "life support system" services and in this respect excludes categories of ecosystem services, such as wildlife habitat.

The results of Phillips and Silverman's (2007) analysis suggests there are ecosystem service values associated with the Tongass National Forest and these values are, as the resource-by-resource analyses presented in the other sections of this EIS suggest, undoubtedly high. These estimates are not, however, suitable for a detailed comparison of alternatives at the Forest level.

The uncertainty surrounding the accuracy of these estimates is compounded by the difficulty involved in accurately quantifying the effects of the alternatives on physical and biological resources in unit values. As Kline (2006, 15) notes, even if we were to accept this overall estimate as a reasonable benchmark for the total existing value of Tongass-related ecosystem services, "total ecosystem values provide little guidance to policy or management decisions unless these decisions can be expressed as marginal or incremental changes in ecosystem services." With respect to wetlands, which make up 91 percent of the annual ecosystems services value estimated by Phillips and Silverman, for example, the impacts are evaluated in this EIS in terms of potential risk based on projected road building and acres identified as suitable for harvest. Impacts are not quantified in terms of acres lost or acres of wetland function impaired.

However, as noted earlier, the fact that no monetary value is assigned to ecosystem services in this document does not lessen their importance in the decision making process. A large proportion of this document is devoted to assessing impacts to the Forest resource that cannot be readily expressed in monetary terms.

It should also be noted that ongoing initiatives in Southeast Alaska to develop ecosystem services markets such as the Fuels for Schools program, thinning of second growth for wildlife habitat improvement, and implementation of practices and technologies to reduce the carbon 'footprint' of Forest Service operations will con tinue under all of the alternatives.

It is important to recognize when evaluating the potential effects of the alternatives on non-commodity forest values, such as non-use values, ecosystem services, and quality of life issues, that there are a number of options available and in place to protect these values and resources. Under the current Forest Plan, LUDs specify ways of managing an area of land and the resources it contains. LUDs may emphasize certain resources, such as remote recreation or old-growth wildlife habitat, or combinations of resources, such as providing scenic quality in combination with timber harvesting. Each LUD has a detailed management prescription, which includes standards and guidelines.

Under the current Forest Plan, there are 19 LUDs that range from Wilderness to Timber Production, in terms of the level of development permitted. While each LUD has a different purpose and management emphasis, they may be generally grouped into four categories based on the kind of effects they potentially create. These four categories are wilderness, natural setting, moderate development, and intensive development. Timber management and other types of development are only allowed in the moderate and intensive development LUDs. Not all lands allocated to development LUDs are available for timber production. Under the current Forest Plan (Alternative 5), 3.6 million acres or 21 percent of the Forest is allocated to development LUDs. Approximately 687,000 acres of this area, or 4 percent of the Forest, suitable and scheduled for timber production (Table 3.22-27). This total includes both productive old growth and young-growth acreage. Under Alternative 1, the most restrictive alternative from a development perspective, 5 percent of the Forest would be allocated to development LUDs, with approximately 144,000 acres estimated to be suitable for timber production.

Table 3.22-27
Land Use Designations and Mapped Suitable Lands by Alternative (1,000s Acres)

LUD Group/Alternative	1	2	3	4	5	6	7

Percent of Total	1	2	3	5	4	4	6

[1] Scheduled suitable acres appropriate for harvest occur in moderate and intensive development LUDs only.

Under the current Forest Plan, timber management activities are governed by a large number of rules and regulations designed to protect or mitigate negative impacts to resources. These standards and guidelines, presented in Chapter 4 of the current Forest Plan, address the following resource areas and apply to Alternative 5, the No-Action Alternative, in this EIS:

- Air
- Beach and Estuary Fringe
- Facilities
- Fire
- Fish
- Forest Health
- Heritage Resources
- Karst and Caves
- Lands
- Minerals and Geology
- Recreation and Tourism
- Riparian
- Rural Community Assistance
- Scenery
- Soil and Water
- Subsistence
- Threatened, Endangered, & Sensitive Species
- Timber
- Trails
- Transportation
- Wetlands
- Wildlife

A number of changes to the Forest Plan text are being proposed under the action alternatives, based on the Forest Plan 5-Year Plan Review and Forest Service staff recommendations. Most changes were incorporated into the Proposed Forest Plan (Land and Resource Management Plan), which accompanied the Draft EIS. These changes were modified and updated for the Final EIS and the major changes being proposed are summarized in Chapter 2. The Final Proposed Forest Plan forms the basis for Alternatives 1, 2, 3, and 6. A summary of the major differences between the Final Proposed Forest Plan and the current Forest Plan are summarized below.

Management Prescriptions

- Edits and clarifications were made regarding karst management programs, sacred site protection, minerals and geology, off-highway vehicle use, scenery management, and other areas for most LUD prescriptions
- Substantial edits and clarifications were made to the Wilderness and Wilderness National Monument LUD prescriptions

Forest-wide Standards and Guidelines

- Clarifications and edits were made to the standards and guidelines regarding steep slopes and soil stability, Class III and IV streams, karst and cave resources, minerals and geology, recreation and tourism, scenery, off-highway vehicle use, road storage and decommissioning, and other resources.

- New sections were added to Chapter 4 on Invasive Species and Plants, and new standards and guidelines on sacred site protection.
- Conversion of the goshawk foraging habitat and the marten habitat standards and guidelines in the Wildlife section to a Forest-wide legacy standard and guideline in the *Wildlife* section.
- Revision of the goshawk nesting habitat standard and guideline in the *Wildlife* section.
- The requirement to conduct inventories to determine the presence of nesting goshawks for proposed goshawks that affect goshawk habitat is included in the Final Proposed Forest Plan.

Alternatives 4 and 7 also follow the Final Proposed Forest Plan, with some exceptions including the following:

- The Beach and Estuary Fringe buffer is changed to 500 feet along the beach fringe and 1,000 feet around estuaries under Alternative 7
- Neither the goshawk foraging habitat, the marten habitat, nor the new Legacy Standards and Guidelines would be implemented
- The goshawk nesting standard and guideline would not be implemented

As a result, the levels of resource protection are expected to be lower in these areas under Alternatives 4 and 7. In addition, the Old-Growth Habitat LUD and its management prescription is not used under Alternative 7, resulting in a reduction in protection for old-growth habitat.

Although data availability and specificity continue to be a challenge to refining the scale at which ecosystem service provision is assessed and valued, measurement, modeling, and valuation of ecosystem service efforts are increasing rapidly in scope, resolution, and ability to reflect system complexities. In addition, markets for ecosystem services are a topic of growing interest within the Forest Service, its partners and stakeholder groups. A prominent challenge to establishment of ecosystem service markets is the understanding of the current provision of ecosystem services as a baseline, against which progress (termed by economists as additionality) can be measured. A second challenge is to understand in a forward-looking manner the potential direct and indirect benefits of emerging market opportunities related to ecosystem services. Ongoing initiatives in Southeast Alaska illustrate some of the potential in this regard and include the Fuels for Schools programs, thinning of second growth for habitat, and implementation of practice and technologies to reduce the carbon ‘footprint’ of Forest Service operations, among other examples.

Natural Amenities and Quality of Life

As discussed in the Affected Environment portion of this section, natural amenities and local quality of life have increasingly been recognized as important factors that serve to attract and retain residents. It is, however, very difficult to determine the effect of the different alternatives on local amenities and, further, on the economic activity that these amenities are believed to indirectly generate. In most cases and localities the impacts of the action alternatives relative to the no-action alternative on amenities are not expected to be significant enough in themselves to result in measurable changes in economic activity.

Tongass National Forest Budget

The Forest Service budget is appropriated through Congress on a yearly basis. National forest budget requests are considered as part of total budget requests submitted to the United States Congress by the executive branch each year, with Congress having final say. The relevant portions of the Tongass National Forest budget are summarized for 2007 in Table 3.22-28. In general, funding for the Tongass National Forest has followed a downward trend in recent years. The Fiscal Year (FY) 2007 budget allocation was, for example, approximately $46 million (Table 3.22-28) compared to approximately $72 million in 2001 (see Table 3.22-26 in the 2003 SEIS [USDA Forest Service 2003b]). This overall decline in funding means that an increase in overall funding would be required relative to 2007 levels to fully implement the Forest Plan under all of the alternatives, including Alternative 5, No Action.

Variations in the level of timber harvest would affect the cost of operating the related programs including the following budget items, which include all the resource support, like wildlife biologists, necessary for timber harvesting.

The budget items that would be affected by variations in timber harvest volumes are as follows:

NFPN – Land Management Planning
NFIM – Inventory and Monitoring
CMRD – Roads Capital Improvements & Maintenance
NFTM – Timber Management
NFVW – Vegetation and Watershed Management

The amounts required to adequately fund these budget items would vary by alternative based on the estimated level of timber harvest. Projected budget requirements would be higher for these items under Alternatives 4, 5, 6, and 7, with Alternative 1 requiring the lowest amount of funding for timber management related activities. As the preceding discussion suggests, budget shortfalls are likely in the future, especially for the more timber-intensive alternatives.

Table 3.22-28
Fiscal Year 2007 Budget Allocation by Resource Item

Fund Code	Budget Line Item		Allocation
	National Forest System		
NFPN	Land Management Planning	$	1,306,700
NFIM	Inventory and Monitoring		1,945,500
NFRW	Recreation/Heritage/Wilderness		4,240,600
NFWF	Wildlife and Fish Habitat Management		3,570,100
NFTM	Timber Management		12,699,300
NFVW	Vegetation and Watershed Management		2,430,400
NFMG	Minerals		1,017,800
NFLM	Landownership Management		1,625,700
NFLE	Law Enforcement		
	Total	$	28,836,100
	Wildland Fire Management		
WFPR	Fire Preparedness	$	890,700
WFHF	Hazardous Fuels		
WFSU	Fire Operations		
	Total	$	890,700
	Capital Improvement & Misc.		
CMFC	Facilities Capital Improvements and Maintenance	$	2,752,600
CMRD	Roads Capital Improvements and Maintenance		12,179,400
CMTL	Trails, Capital Improvements and Maintenance		1,412,200
	Total		16,344,200
Total		**$**	**46,071,000**

Note: This table only summarizes those portions of the 2007 Tongass National Forest allocation that pertain to this analysis.
Source: USDA Forest Service 2007h.

Payments to the State

As noted in the Affected Environment discussion, the *Secure Rural Schools* legislation expired in 2006 with the last payments under this authorization made in December 2006. However, payments under this legislation were extended for 2007 as part of the Iraq Accountability Appropriations Act of 2007, which was signed into law on May 25, 2007 (USDA Forest Service 2007i).

Cumulative Effects

This section considers the incremental effects of the alternatives when added to other past, present, and reasonably foreseeable actions. The effects of past and present actions on the economic and social environment are included in the Affected Environment portion of this section, which discusses the regional economy, as well as providing a subregional overview, and assessing potential impacts at the community level. These sections summarize current employment levels and other key aspects of natural resource-based industries, and also assess recent trends.

The effects analyses presented in the preceding sections also take into consideration reasonably foreseeable actions. The impact analyses that address the wood products industry include, for example, projected future harvest levels for other land ownerships in Southeast Alaska. The effects of past and present harvest actions on other land ownerships are also implicitly incorporated into this analysis because they influence projected future levels of timber harvest. The influence of other factors not directly related to the Tongass, such as the major shifts in the markets served by Alaskan sawmills over the past decade, are also considered as part of the analysis.

The continued growth in the number of cruise ship passengers visiting the region is one of the major trends in recreation in Southeast Alaska. The effects of the alternatives are considered in conjunction with this trend because it underpins current and future recreation demand on the Tongass. In addition, the recreation and tourism economic impact analysis includes estimated non-Tongass-related recreation employment, as well as the potential effects of the alternatives on the supply of recreation opportunities on the Tongass.

Other reasonably foreseeable future actions include an expected growth in recreation and tourism businesses based on the continued growth in the cruise ship industry, as well as the development of additional fishing and other lodges. This type of development would facilitate additional recreation and tourism in the region and on the Forest. Human settlement expansion is expected to occur around the region's larger cities, such as Juneau and Ketchikan, with residential expansion also expected as a result of state land auctions. These developments would likely result in increased demand for a range of recreation activities, with some developments favoring developed recreation opportunities, and others more dependent on undeveloped lands.

Reasonably foreseeable actions on NFS lands include the projected levels of future timber harvest and development that are used in the preceding analysis to assess the potential impacts of the alternatives on the regional and local economies. These projected activities were also used to assess the potential impacts of the alternatives on the supply of recreation opportunities and recreation use and demand.

Other reasonably foreseeable actions include transportation and utility developments proposed by the State of Alaska. These proposals are summarized in the *Transportation and Utilities* section of this document. A total of 1,523 miles of roads are projected to be constructed on non-NFS lands in Southeast Alaska over the life of the Plan (100+ years) under each of the alternatives (see Table 3.12-3 in the *Transportation and Utilities* section). Most of the projected non-NFS roads are forest roads that would be developed for timber harvest, but the total miles also include roads likely to be built to serve communities, such as the Juneau access road on the east side of Lynn Canal. This road, and other road corridors covered by Public Law 109-59, would, if approved under NEPA and funded, connect additional areas in Southeast Alaska to the continental highway system and improve transportation between communities. They would also improve access for recreation use and in some cases would likely facilitate new types of use.

It is not possible at this time to predict exactly which roads would be developed or their likely impact on future recreation patterns and associated employment. None of the alternatives are expected to affect this type of future road development, which would be expected to go forward regardless of the selected alternative. The overall cumulative effect of new regional road corridors viewed in conjunction with the proposed Forest Plan alternatives would be a trend toward more developed recreation opportunities that would be relatively high under Alternative 7 and relatively low under Alternative 1. Planned timber harvest activities on adjacent private and Native Corporation lands would also result in a cumulative trend toward more developed recreation opportunities that would be most pronounced under Alternative 7 and least pronounced under Alternative 1.

Mining activities are expected to expand at existing sites, including Greens Creek on Admiralty Island and Berners Bay north of Juneau, with an increase in mining exploration and new development anticipated. Continued mining at existing sites and ongoing exploration efforts would likely support existing levels of mining employment and income. This employment and income would increase if there were an increase in exploration and development.

Regional energy and transmission projects are also expected to occur, including the Swan-Tyee transmission line and the Juneau-Hoonah transmission line. These projects are expected to improve and expand local and regional electrical service and reliability.

Subregional Overview and Communities

Introduction

The preceding section of this document addressed the potential impacts of the proposed alternatives upon the regional economy as a whole. Potential impacts would not, however, be viewed similarly by all boroughs or communities in Southeast Alaska or distributed equally among them. It is, therefore, important to consider the potential effects at a more detailed geographic scale. The following section is divided into two parts. The first part, entitled Subregional Overview, addresses the economic and social composition of the boroughs and census areas (CAs) that comprise Southeast Alaska, as well as providing summary data at the community group level. This discussion provides an important perspective on the likely distribution of the potential effects identified in the regional economy analysis, as well as setting the stage for the second part of this section, which discusses the potential effects of the alternatives on each of Southeast Alaska's 32 communities.

Subregional Overview

Addressing potential effects at the subregional level can be difficult because the types of data available at the state or regional level are often not available for smaller localities. In addition to problems arising from inadequate data, the lack of detailed information on the exact location of expected harvests and on the competitive position of individual firms makes it impossible to know which jobs or firms may be affected under a given alternative. Any attempt to provide numerical estimates of long-term impacts at the community level would be prone to error, and give a false sense of accuracy and certainty. As a result, the following analysis presents a more detailed picture of the current situation and past trends at the Borough/CA and community group levels, but does not attempt to quantify potential impacts by alternative.

Economic developments are discussed in the following sections using data compiled at the borough/CA level, as well as employment data compiled by the Alaska Department of Labor (Alaska DOL) at the community group level. Community groups are sub-areas of boroughs and CAs developed by the Alaska DOL. Some of the community groups consist of one community; others include several communities (see Table 3.23-6). Information at the community group level provides a more detailed picture of local employment patterns than is usually available.

Southeast Alaska Boroughs and Census Areas

There are large differences in the economic structure and development of the boroughs and CAs (referred to as the "boroughs" in the following discussion) that comprise Southeast Alaska. A common problem encountered in the analysis of the Southeast Alaska economy is that, owing to its relative size, Juneau dominates statistics at the regional level. As a result, regional trends in population, employment, or income tend to closely represent developments in Juneau and often do not reflect changes in other boroughs. By analyzing certain economic statistics at the borough level, differences in economic structure and trends that are obscured at the regional level, are more apparent. The following sections discuss population, employment, and income trends at the borough level.

Population

The population of Alaska grew during the 1980s and 1990s increasing from about 402,000 in 1980 to approximately 627,000 in 2000, an increase of 56 percent. Southeast Alaska's population increased by 36 percent over the same time period. Increases at the borough level ranged from 8 percent for Wrangell-Petersburg to

57 percent and 61 percent for Juneau and Prince of Wales-Outer Ketchikan, respectively, with Juneau accounting for about 55 percent of Southeast Alaska's population growth over this period. Population increases were larger in the 1980s than in the 1990s in all cases, and population in the Northern Complex, Wrangell-Petersburg, and Prince of Wales-Outer Ketchikan actually declined between 1990 and 2000 (Table 3.23-1).

Table 3.23-1

CA=Census Area
[1] 1990 data are for the Skagway-Yakutat-Angoon Census Area. 2000 data combine the Skagway-Hoonah-Angoon Census Area and Yakutat Borough. Yakutat Borough was incorporated in 1992.
Source: Alaska DOL 2001a, 2007a; U.S. Census Bureau 1995.

Alaska has continued to grow since 2000 with total population increasing by 7 percent between 2000 and 2006. Southeast Alaska, in contrast, lost population over this period, with the total population decreasing by an estimated 3,029 people or about 4 percent. All of the boroughs have lost population since 2000, with the largest absolute decrease (-885 people) occurring in Ketchikan Gateway Borough. Juneau and Sitka experienced relatively modest decreases in population from 2000 to 2006, less than 0.5 percent in both cases (Table 3.23-1).

Components of regional population change for 2000 through 2006 indicate that all of the boroughs in Southeast Alaska experienced natural increase (more births than deaths) over this period (U.S. Census Bureau 2006). All of the boroughs also experienced net out-migration (more people leaving than moving in) and in all cases the net loss of population through out-migration exceeded the net gain through natural increase. Juneau City and Borough experienced the largest absolute net out-migration over this period.

Alaska DOL released new statewide population projections in 2007 (Alaska DOL 2007h). These projections extend from 2010 through 2030, with low, middle, and high estimates available at the borough level at 5 year intervals. The general trend from 2006 to 2030 is for some degree of population growth for all Alaska regions, with the exception of Southeast Alaska. The boroughs with the greatest levels of annualized projected population decrease from 2006 to 2030 are both located in Southeast Alaska. Skagway-Hoonah-Angoon CA and Haines borough are projected to see annual decreases in population of 1.8 percent and 1.5 percent over this period, respectively (Alaska DOL 2007h).

Population in Alaska as a whole is projected to increase between 2006 and 2030 under all three sets of estimates, with anticipated increases ranging from 9 percent to 42 percent. Population estimates for Southeast Alaska anticipate a 19 percent decrease (low), a 7 percent decrease (middle), or a 5 percent increase (high) over the same time period. Population is expected to decrease in all Southeast Alaskan boroughs under the low set of projections, for all the boroughs except Juneau (+5 percent) under the middle set, and all boroughs except Juneau (+19 percent), Sitka (+11 percent), and Yakutat (+3 percent) under the high set (Alaska DOL 2007h).

Employment

Total full- and part-time employment is presented by borough for 1990 and 2000 in Table 3.23-2. These data compiled by the U.S. Department of Commerce, Bureau of Economic Analysis include proprietors and self-employed workers. These data indicate that overall employment in Southeast Alaska increased by approximately 11 percent during the 1990s, with population increasing by 6 percent over the same period (Table 3.23-1). Employment increased in all boroughs with the exception of Ketchikan Gateway, which experienced a net loss of 529 jobs or 4.9 percent of total employment over this period. Total employment in Juneau increased by 4,036 jobs or 22 percent. Employment in Haines also saw a relatively large gain, increasing by 31 percent or 520 jobs.

Table 3.23-2
Borough/Census Area Employment, 1990 and 2000

	Total Employment[1]		Wood Products[2,3]			Lodging, Rest. & Rec[2,3,4]

[1] These data, compiled from U.S. Department of Commerce, Bureau of Economic Analysis (BEA) data and are for full and part-time employment, including proprietors and self-employed.
[2] These data, compiled from Alaska DOL (NAWS) data (Alaska DOL 2006c) and the 1997 Forest Plan Revision Final EIS, do not include proprietors and self-employed workers. Bureau of Economic Analysis data, the source for the total employment column, is not available at this level of disaggregation.
[3] The percent of local total is benchmarked against total NAWS employment, which excludes proprietors and self-employed, not the Bureau of Economic Analysis numbers shown in the left column.
[4] Lodging, Restaurants, and Recreational and Entertainment Services. This measure does not directly reflect recreation and tourism-related employment but is included as an indicator of trends and relative concentration of recreation and tourism-dependent jobs. The numbers presented here do not include proprietors or the self-employed and, therefore, are likely underestimates as proprietors and self-employed workers tend to comprise a large share of total employment in these sectors.
[5] Aggregate of Skagway-Hoonah-Angoon Census Area and Yakutat Borough.
Source: Alaska DOL 2006c; U.S. Department of Commerce, Bureau of Economic Analysis 2002; USDA Forest Service 1997a (Table 3-154).

Employment in wood products and lodging, restaurants, and recreational and entertainment services is also summarized by borough in Table 3.23-2. These data compiled by the Alaska DOL are for covered employment only. Covered employment data include workers covered by State or federal unemployment insurance laws programs. Covered employment does not include proprietors or self-employed workers. As a result, the numbers presented in Table 3.23-2 are likely underestimates. This is particularly the case with lodging, restaurants, and recreational and entertainment services because proprietors and self-employed workers tend to comprise a large share of total employment in these sectors. U.S. Department of Commerce, Bureau of Economic Analysis data, which include proprietors and self-employed workers, are not available at this level of disaggregation.

Employment in the wood products sector declined in all boroughs during the 1990s, with the largest absolute loss (1,046 jobs) occurring in Ketchikan Gateway. Losses ranged from a low of 44 percent of 1990 wood products employment in Northern Complex to 100 percent in Sitka and Haines. The wood products sector accounted for 433 and 141 jobs in Sitka and Haines in 1990, respectively. These sharp declines in employment in part reflect the years selected for comparison. Wood products employment, which has followed cyclical trends over the past two decades, peaked in 1990 (see Figure 3.22-6 in the *Economic and Social Environment* section). A comparison between 1985 and 1999, for example, would show a less dramatic decline. Comparing two points in time also has the effect of suggesting a linear trend that may not be the case. Wood products employment in Wrangell-Petersburg CA, for example, declined by 64 percent between 1990 and 2000, but actually increased by about 88 percent between 1995 and 2000.

That said, APC and KPC ceased their Southeast Alaska operations in the 1990s and mill closures in Ketchikan, Sitka, and Wrangell had dramatic effects on these communities because they eliminated their main source of private sector year round employment. In addition, the seasonal but well-paid logging activities in Prince of Wales-Outer Ketchikan, Wrangell-Petersburg, and Skagway-Hoonah-Angoon were reduced over this period (Gilbertson 2004). As a result, by 2000 wood products accounted for a relatively small share of total employment in most boroughs. Wood products did, however, continue to comprise a relatively large share of employment in Prince of Wales-Outer Ketchikan (15.1 percent), Ketchikan Gateway (9.4 percent), and Northern Complex (9.0 percent) (Table 3.23-2).

In contrast to wood products employment, employment in lodging, restaurants and recreation-related services demonstrated strong gains between 1990 and 2000. The contrast between losses in wood products employment and gains in lodging, restaurants and recreation-related employment is consistent with overall trends discussed in the *Economic and Social Environment* section, but there is considerable variation across boroughs. Employment in this category in Haines, for example, more than doubled, with lodging, restaurants and recreation-related services accounting for 22 percent of total employment in 2000. The Wrangell-Petersburg CA, on the other hand, saw a substantial decrease (22 percent) in employment in this category, which represented just 6 percent of total employment in 2000. Certain boroughs (and, by extension, the communities that they encompass) have benefited more from the expansion of the tourist-related economy than others.

Employment data for 2000 and 2005 are summarized in Table 3.23-3 and indicate that while statewide employment increased by 9.8 percent over this period, employment in Southeast Alaska stayed relatively constant increasing by just 0.7 percent or 333 jobs. Employment in Juneau declined over this period, with 1,041 fewer jobs in 2005 than in 2000. Employment stayed relatively constant in Haines (-19 jobs) and increased in all the other boroughs, with the largest absolute increase occurring in Sitka (777 jobs) (Table 3.23-3).

Covered employment data compiled by Alaska DOL for 2005 are also presented in Table 3.23-3 and shown graphically in Figure 3.23-1. These data are not directly comparable with those presented in Table 3.23-2 because of the change from the SIC to NAICS measurement systems employed by federal and state agencies in 2001. Comparison of these data does, however, suggest that wood products has continued to decline as a share of total employment in all Southeast Alaska boroughs since 2000 (see Tables 3.23-2 and 3.23-3). Employment in the leisure and hospitality sector accounted for about 10 percent of total Southeast Alaska covered employment in 2005, ranging from 6.6 percent of total employment in Wrangell-Petersburg to 18.9 percent in Yakutat (Table 3.23-3).

Table 3.23-3 and Figure 3.23-1 highlight the distinction between northern and southern boroughs. With the exception of Skagway-Hoonah-Angoon, there was no wood products employment in the northern boroughs in 2005. Nearly all of the covered forestry and logging and wood products manufacturing employment in Southeast Alaska (96 percent) is concentrated in the southern boroughs. Leisure and hospitality employment, by contrast, generally shows higher concentrations in the north, with northern boroughs accounting for 70 percent of total regional employment in this category.

Table 3.23-3

[1] These data, compiled from U.S. Department of Commerce, Bureau of Economic Analysis (BEA) data and are for full and part-time employment, including proprietors and self-employed.
[2] These data, compiled from Alaska DOL (NAWS) data (Alaska DOL 2006b), do not include proprietors and self-employed workers. Bureau of Economic Analysis data, the source for the total employment column, is not available at this level of disaggregation.
[3] The percent of local total is benchmarked against total NAWS employment, which excludes proprietors and self-employed, not the Bureau of Economic Analysis numbers shown in the left column.
[4] Leisure and hospitality does not directly reflect recreation and tourism-related employment but is included as an indicator of the relative concentration of recreation and tourism-dependent jobs. This sector includes the Arts, Entertainment, and Recreation and Accommodation and Food Services sectors. The numbers presented here do not include proprietors and self-employed and, therefore, are likely underestimates as proprietors and self-employed workers tend to comprise a large share of total employment in these sectors.

Income

Average real per capita income in Southeast Alaska (expressed in constant 2005 dollars) increased by 4 percent between 1996 and 2005. The change from 1996 to 2005 varied by borough, ranging from a decrease of 1 percent in Juneau to relatively large increases in the smaller northern boroughs (Haines [16 percent], Skagway-Hoonah-Angoon [20 percent], Yakutat [18 percent]). Average real per capita income increased in Alaska (11 percent) and nationwide (15 percent) over this period

The absolute level of per capita income is considerably lower for Prince of Wales-Outer Ketchikan, indicating that in 2005, on average, residents at this area received 36 percent less income than the regional average. Per capita incomes are above the regional average in Ketchikan (111 percent), Haines (110 percent), and Juneau (106 percent) (Table 3.23-4).

Note:
1. Per capita income figures for 1996 are adjusted for inflation and presented here in 2005 dollars.
Source: U.S. Department of Commerce, Bureau of Economic Analysis 2007a.

Dividends, interest, and rent decreased as a share of total income from 1996 to 2005 in Alaska, the U.S as a whole, and all Southeast Alaska boroughs (Table 3.23-5). Transfer payments increased as a relative share of employment over the same period in all Southeast Alaska boroughs, as well as in Alaska as a whole and nationwide. Increases in Southeast Alaska ranged from 1.4 percent in Sitka to 6.8 percent in Yakutat Borough.

Notes:
1. Earnings includes wages and salaries, other labor income, and proprietors' income.
2. Transfer payments consist mainly of government payments to individuals, including retirement, disability, and unemployment insurance benefit payments, income maintenance payments, and veterans benefit payments. Government payments to individuals in Alaska include Alaska Permanent Fund benefits, which are derived from oil revenues and paid to every resident.
3. Percent of total income.

Source: U.S. Department of Commerce, Bureau of Economic Analysis 2007a.

Earnings as a share of personal income increased from 1995 to 2004 in Southeast Alaska (0.5 percent), Alaska (1.7 percent), and the U.S as a whole (2.3 percent) (Table 3.23-5). Earnings decreased as a share of total income in all the southern boroughs, with the largest decrease (-7.7 percent) occurring in Prince of Wales-Outer Ketchikan, as well as Skagway-Hoonah-Angoon and Yakutat. Earnings increased as a share of total income in Haines, Juneau, and Sitka.

Alaska DOL Community Groups

In this portion of the document, the employment data provided by Alaska DOL is analyzed using the community groups defined by that agency—the most detailed level available for this data. At this level of disaggregation there is a much greater potential for substantial errors in the data. Changes in reporting jurisdictions or industry definitions, for example, may result in large and abrupt changes in reported employment for a given community or industry with no underlying change in actual employment patterns. It is also important to remember that Alaska DOL community groups are not necessarily synonymous with actual communities. The individual communities included in each community group are identified in Table 3.23-6. The following discussion focuses on the wood products and recreation and tourism industries. Data are presented for 1990 and 1999, which is the most recent year that data are available in this format.

Table 3.23-6
Alaska DOL Community Groups Defined

Boroughs and Census Areas	Community Groups	Communities/Places
City & Borough of Juneau	Juneau	Auke Bay, Berners Bay, Douglas, Dupont, Fritz Cove, Hawk Inlet, **Juneau**, Lemon Creek, Lena Cove, Lynn Canal, Mendenhall Valley, North Douglas, Salmon Creek, Snettisham, Switzer Creek, Taku Harbor, Taku Lodge, Tee Harbor, Thane, and West Juneau.
Ketchikan Gateway Borough	Ketchikan	Carlanna, Charcoal Point, Clover Pass, Herring Cove, **Ketchikan**, Mountain Point, Mud Bay, North Tongass Highway, Peninsula Point, Pennock Island, Point Higgins, Refuge Cove, **Saxman**, Shoreline Drive, Thomas Basin, Totem Bight, Upper Nickeyville, Wacker, and Ward Cove.
	Revillagigedo	Fire Cove, Gedney Pass, George Inlet, Gravina Island, Guard Island, Hassler Pass, Loring, Neets Bay, Princess Bay, Shoal Cove, and Twin Peaks.
Haines Borough	Haines	Eldred Rock, Excursion Inlet, **Haines**, Letnikof Cove, Moose Valley, Mosquito Lake, Pleasant Camp, Porcupine, Port Chilkoot, and Saint James Bay.
Sitka Borough	Baranof	Baranof, Big Port Walker, Chatham, Corner Bay, False Island, Lake Eva, Little Port Walter, Port Armstrong, Port Conclusion, Rodman Bay, Saook Bay, Todd, and Warm Spring Bay.
	Sitka	Biorka Island, Chichagof, Cobol, Deep Bay, Goddard, Halibut Point, Jamestown Bay, Japonski Island (Mt. Edgecumbe), Katlian Bay, Klag Bay, Nakwasina Cove, Redfish Cape, Saint John Baptist Bay, Schulze Cove, **Sitka**, and Sitka Logging Camp.
Yakutat Borough	Yakutat	Situk and **Yakutat**
Angoon-Hoonah-Skagway Census Area	Chatham Strait	**Angoon**, Catherine Island, Cube Cove, Hanus Bay, **Tenakee Springs**, Tyee, and Whitewater Bay.
	Gustavus	Bartlett Cove, Cape Spencer, and **Gustavus** (Strawberry Point).
	North Chichagof	**Elfin Cove**, Gull Cove, **Hoonah**, Idaho Inlet, Lisianski, **Pelican**, Port Althorp, Port Frederick, and Yakobi Island.
	Stephens Passage	Cape Fanshaw, Five Fingers, Freshwater, Bay, Funter Bay, Hobart Bay, Point Retreat, Port Houghton, Sawyers Landing, Sumdum, and Windham Bay.
	Skagway	Clifton, and **Skagway**.
Prince of Wales-Outer Ketchikan	Central Prince of Wales	**Craig**, **Hollis**, and **Klawock**.
	Southeast Prince of Wales	Bokan Mountain, Campbell, Dall Island, Dora Bay, Kendrick Bay, Klakas Inlet, Rose Inlet, Twelvemile Arm, View Cove and Waterfall.
	Hydaburg	**Hydaburg**
	North Prince of Wales	Cape Pole, Coal Bay, **Coffman Cove**, **Edna Bay**, El Capitan, **Kasaan**, Labouchere Bay, Little Naukati Bay, **Naukati Bay**, Noyes Island, **Point Baker**, Port Alice, **Port Protection**, Ratz Harbor, Red Bay, Salt Chuck, Shakan, Steamboat Bay, **Thorne Bay**, Thorne Island, Tokeen, Warren Cove, and **Whale Pass**.
	Metlakatla	Annette, Mary Island, and **Metlakatla**.
	Hyder	Hidden Inlet, **Hyder**, Smeaton Bay, Tongass, and Tree Point
	Cleveland Pen.	Bell Island, **Meyers Chuck**, Union Bay and Yes Bay.
Wrangell Petersburg Census Area	Kake	**Kake**.
	Kuiu Island	Alvin Bay, Cape Decision, Coronation Island, Duncan Canal, Fairway Island, Hamilton Bay, Kah Sheets Bay, **Port Alexander**, Rowan Bay, Saginaw Bay, Security Bay, Tebenkof Bay, and Washington Bay.
	Petersburg	Kupreanof, Mitkof Island, **Petersburg**, Scow Bay, and Vank Island.
	Thomas Bay	Thomas Bay.
	Wrangell City	**Wrangell**.
	Wrangell Island	Bradfield River, Burnette Inlet, Deer Island, Ernest Sound, Etolin Island, Kakwan Point, Roosevelt Harbor, Saint John Harbor, Tyler Logging Camp, and Zarembo Island.

Notes:
1. Some of these community groups have been renamed to more clearly represent the communities/places included.
2. The listing of communities/places included in each community group identifies named places in these areas. Some of these places are presently uninhabited.
3. Communities identified in bold are discussed in the Communities section of this document.

Source: USDA Forest Service 1997a (Table 3-155).

The following tables and figures provide some insight into which areas are more likely to be affected by the alternatives, as well as those that are likely to have been affected by changes in the economy since 1990.

Employment information, presented by community group in Table 3.23-7, shows an extremely high variation in the rate of job creation (or loss) experienced by the different community groups. The highest positive or negative changes are, not surprisingly, concentrated in those groups with the smallest total employment numbers. This highlights an important aspect of community level impacts—the most severe impacts (relative to total local employment) are often experienced in smaller communities, where even small job losses may be large relative to total employment.

Smaller communities also often exhibit higher concentrations of employment in a single industry, such as logging camps or resorts and fishing lodges.

Table 3.23-7
Employment by Community Group, 1990 to 1999

[1] Full and part-time average annual employment. Self-employed people and proprietors are not included in this data-set.
[2] Wood products includes both mill and logging employment.
[3] Lodging, Restaurants and Recreational and Entertainment Services. This measure does not directly reflect recreation and tourism-related employment, but is included as an indicator of trends and relative concentration of recreation and tourism-dependent employment.
Source: Alaska DOL 2002.

Communities

Community is a concept with multiple dimensions and definitions. Basic definitions of community include: 1) a geographic/political entity, such as a town or village; 2) a network of people with shared values, world views, or identities (sometimes called a community of meaning), such as an ethnic or racial group (e.g., Native Alaskans) or an occupational group (e.g., loggers); 3) a working social system; 4) a rural social landscape, which would include the first three definitions in a rural setting; 5) a community of interest, or people with a common stake, profession, interest, activity, or set of values, who may live far apart (e.g., anglers, environmentalists, off-road-vehicle operators).

This section uses the geographic/political community—towns and villages—as its basis for several reasons. There are relatively few communities in Southeast Alaska, they are typically isolated geographically, most are recognized as being unique, and data are more commonly available at this level (although some local economic data is compiled by the State for groups of communities). Geographic/political communities represent an aggregate of individuals and it is important to remember that residents within the same community may be affected differently by the same action. Potential effects that do not appear that significant when viewed at a community level may be very significant for the individuals that are directly affected.

Community Assessments

The 1997 Forest Plan EIS included discussions of 32 Southeast Alaska communities with a state land selection base. These discussions provided brief descriptions of each community, including aspects of their histories, population trends, economic bases, and the subsistence resources used by each community. Each community discussion also included a summary of the public comments and testimony received by the Forest Service on the 1990 Draft EIS, 1991 SDEIS, and the 1996 Revised Supplement. Much of the baseline community information provided in those discussions was taken from the Alaska Department of Community and Regional Affairs (Alaska DCRA) *Community Profiles* (1996) and 1990 U.S. Census data. Subsistence information was mainly based on the findings of the 1989 Tongass Resource Use Cooperative Survey (TRUCS). Updated summary data are presented by community in Table 3.23-8. These data suggest that these communities are diverse in terms of population, income, and subsistence use. There is also a good deal of variation within many of the communities, as reflected by the range of public comments received during preparation of the 1997 Forest Plan EIS and the 2003 SEIS (USDA Forest Service 1997a; 2003b).

This document provides brief updates of the affected environment sections of the community discussions, where applicable. The reader is referred to the 1997 Tongass Forest Plan EIS for more detailed information on community history, economic base, and subsistence resources. The 1987 TRUCS data used in the 1997 Forest Plan EIS discussions is still the most current consistent source of subsistence information available. Updated information from the ADF&G, Subsistence Community Profile Database is provided in the following discussions, where available.

Data from the 2000 Census has been incorporated in the community discussions, as appropriate. This includes estimates of the number of people who work in differrent industries. These estimates are generally extrapolated from a sample of each community's population with the sample size varying by community. In cases where the community is small, the extrapolation may not be exact but should in most cases provide a general indication of distribution of employment. Employment data are available by community group for 1990, 1995, and 1999 in the planning record for this EIS.

The effects of the alternatives considered in the 1997 Forest Plan EIS were evaluated in terms of community use area effects. Community use areas depict the approximate extent of each community's day-to-day use area. Potential community effects were also estimated with the help of a Socioeconomic Panel and Subsistence Workshop, which were convened to assess the potential effects of the planning alternatives for the 1997 Forest Plan EIS. The Socioeconomic Panel assessed these potential effects in terms of timber employment, tourism/recreation employment, mining employment, economic structure/diversity, community stability, quality of life, recreation opportunities, and access to traditional lifestyles. The Subsistence Workshop involved a group of subsistence specialists who met to offer professional judgement regarding the potential effects of planning alternatives on 30 selected subsistence communities (Juneau and Ketchikan do not meet the federal definition of subsistence community). In addition, the Sitka black-tailed deer habitat capability model output was analyzed for the Wildlife Analysis Areas (WAAs) where each community obtained approximately 75 percent of their average annual deer harvest. This analysis is discussed further in the 1997 Forest Plan EIS. An updated deer habitat capability model-based analysis is used here and is presented in the Wildlife section.

The analysis presented here draws upon these information sources to assess the effects of the seven alternatives under consideration by community. Each community discussion includes a map of that community's use area, as defined by the 1997 Forest Plan EIS. These maps are accompanied by tables that provide summary information on the LUDs and suitable acres in each community use area by alternative. The community use area maps and tables are intended to help community residents (and other readers) gain a better understanding of what management direction is proposed for their immediate surroundings under each alternative.

The summary tables for each alternative compare the acres allocated to types of LUD group by alternative. Variations in the amount of National Forest System land allocated to the different LUD groups under each alternative show what land use opportunities would be available during the next 10 to 15 years within each community use area. The variations in how many suitable acres are programmed for timber management under each alternative provide additional information indicating how much of the local forest environment (that is allocated to LUDs in the Moderate and Intensive Development LUD groups) could potentially be harvested over rotation-length time frames. The tables also present summary information on total suitable acres by alternative, which indicate how much of the community use area's forest land remains available for possible future harvesting. Whether any timber harvesting would actually take place on the suitable lands within the community use area over the next decade would depend on the timber sales that are actually carried out during plan implementation. All proposed timber sales would be evaluated on a project-specific basis in accordance with NEPA.

Analyzing Impacts to Communities

Small, rural communities are seldom self-contained economic units. Although it is possible to describe a community's economic structure, complex social and economic forces, many of which are outside the control of community residents, have great influence on community economics. This makes it difficult to precisely predict the effects of forest-wide management alternatives on individual communities. Forest Service activities provide economic opportunities to the private sector. How that sector and the various industries that comprise it respond depends on many variables in addition to Forest Service management.

Forest plans are programmatic, meaning that they establish direction and allowable activities for broad land areas, rather than schedule specific activities on specific patches of land. This also makes it difficult to predict effects on individual communities. This is a common source of frustration to local residents, who want to know exactly how they and the places they care about could be affected. While many outputs of forest management, such as scheduled timber harvest, generally translate into social and economic activity, such as employment in the timber industry, it is difficult to predict which communities would benefit the most from that activity. Communities may even compete with each other in many instances. Communities that rely on a given resource-related industry would, however, be expected to be the first to benefit or lose from significant changes in planned output levels affecting that industry.

Another factor affecting the accuracy of predicting specific impacts at the community scale is that people and businesses have proven themselves highly adaptable. Researchers have used the term community resiliency (Harris 1996) or community capacity (FEMAT 1993) to describe a community's ability to weather significant changes. Some of the factors judged important for small, rural communities in the Pacific Northwest include community infrastructure, the presence of amenities, social cohesion and effective community leadership, and economic diversity. Some communities will be more effective than others in coping with changes that do result. While information such as population size can be used as a rough proxy for resiliency (generally, larger communities tend to be more resilient than smaller ones), this is not always the case. However, analyses have not been conducted regarding the resiliency of Southeast Alaska communities, and we do not know how well information gained elsewhere applies to understanding Southeast communities. It is also worth noting that while a community as a whole may be resilient to change, individuals within that community will still be negatively affected.

Given these considerations, it is more accurate to identify areas of concern for which the risks of effects from a given alternative are higher or lower, rather than say, "Here is what we know will happen to each and every community." One of the hazards associated with such attempts to assess impacts is that analyses tend to view social and economic conditions as static, failing to consider that economies are dynamic, and adjust to different impacts in different ways.

Potential Effects by Resource Area

The alternatives have implications for specific places on the Forest and particular parts of the community use areas of various communities. They also have potential implications in terms of employment in resource dependent industries and the availability of subsistence resources. The following paragraphs discuss the potential implications for wood products, recreation and tourism, and subsistence in general terms to provide some background to the reasoning employed in the community effects discussions presented in the following sections.

Wood Products

Based on the analysis presented in the preceding section, projected direct wood products employment would be higher than current (2005) levels (499 jobs) under all of the alternatives, except Alternative 1 (Table 3.22-20). These projections assume in all cases that the timber supply would be stable and that the entire NIC I component of the projected ASQ would be harvested under each alternative. These projected increases range from 1.8 times the 2005 harvest level under Alternative 2 to 3.9 times under Alternative 7.

As noted in the preceding section, while forest management activities can generally translate into social and economic activity, it is difficult to predict where this activity will actually occur. It is, however, reasonable to assume that increased harvest levels would likely benefit those communities that have historically been dependent on the wood products industry, including the communities where the existing mills are located. The more timber intensive alternatives, especially Allternatives 4 and 7, assume that an integrated industry would develop over time in response to stable supplies of timber. If this were to occur, much of the associated employment would be in the communities where new facilities would be located.

Recreation and Tourism

The mix of primitive and roaded recreation opportunities would vary by alternative based on the allocation of the Forest to different LUD groups and range from maintaining almost all the existing Inventoried Roadless Areas in a natural condition (Alternative 1) to intensive timber management (Alternatives 4 and 7). Viewed in terms of projected recreation and tourism employment over the next decade, there would be very little difference between the alternatives.

Subsistence

Among the subsistence resources of greatest importance (salmon, other finfish, marine invertebrates, and deer), deer is the only one that is potentially significantly affected by the alternatives. Therefore, the subsistence analysis presented here uses deer as a key indicator for potential subsistence resource consequences concerning the abundance and distribution of the resources. Timber harvest tends to affect deer-related subsistence activities in two ways. In the short run, approximately 20 to 30 years following harvest, deer populations tend to increase in harvested areas. In the long-run, populations tend to decline as the canopy in even-aged forest stands closes, resulting in lower habitat quality. Reductions in habitat quality can be reduced through management (e.g., thinning) of young-growth stands. Deer populations in unharvested areas are likely to remain at fairly constant levels that are typically lower than a comparable harvested area in the short run, but higher in the long run. Road construction also affects subsistence by providing subsistence hunters with ready access to areas that may have been previously inaccessible. This effect may be perceived as either positive or negative depending on the parties involved, as increased access may lead to increased competition for resources. Potential effects are likely to vary by community and may be perceived differently by members of the same or neighboring communities.

While there would be some new road access under all alternatives in the long run, nearly all new roads constructed under the alternatives would be closed following harvest. These roads would, therefore, not be available for use by highway vehicles or high-clearance vehicles. They would, however, be available for access by other methods and would, as a result, have the potential to affect existing subsistence patterns.

The subsistence analysis for deer presented for each community is based on several pieces of information. First, it analyzes recent harvest and harvest trends for the WAAs that comprise each community's community use area. For this analysis, hunters are divided into three groups: residents of the community in question, all rural hunters, and all hunters. Next, it considers the results of deer habitat capability modeling presented in the *Wildlife* section, which addresses current and future habitat capability under each alternative relative to the habitat capability available in 1954. Finally, it draws upon the findings of the 1997 Forest Plan EIS (USDA Forest Service 1997a) because four of the current alternatives are very similar to three alternatives in the 1997 EIS. Alternatives 5 and 6 in this analysis are similar to the selected alternative in the 1997 analysis (Alternative 11) and Alternatives 4 and 7 in this analysis are similar to Alternatives 6 and 2 in the 1997 analysis, respectively. For the 1997 EIS, projected harvest levels were compared with estimated deer habitat capability, which was converted into long-term deer carrying capacities, by alternative in the short term (2005) and long term (2095). This analysis assumed that a deer population at carrying capacity should be able to support a hunter harvest of approximately 10 percent that is both sustainable and provides a reasonably high level of hunter success for their effort. At 20 percent it was assumed that the hunter success for their effort may decrease, and, if the population is at carrying capacity, 20 percent may approach a rate that is not sustainable.

Individual Community Assessments

The following sections present socioeconomic descriptions and assessments of impact for 32 Southeast Alaska communities with a state land selection base. These are presented in alphabetical order.

Angoon

Angoon, located on the west coast of Admiralty Island at the mouth of Kootznoowoo Inlet, has been there so long that no precise date can be established for its original occupation. As the only permanent community on Admiralty Island, Angoon had a population of about 572 in 2000. It remains a traditional Tlingit Alaska Native village with 82 percent of its population identified as Alaska Native in the 2000 Census (U.S. Census Bureau, 2001).

The lands immediately adjacent to Angoon are part of Admiralty Island National Monument-Kootznoowoo Wilderness and would not be affected by any of the proposed alternatives. Other areas within Angoon's community use area would, however, be affected. Angoon's population increased 37 percent between the 1970 and 1990 census. Population was, however, approximately 13 percent below the 1990 level in 2000 and continued to decline in the first part of this decade, with an estimated total population of 497 in 2005. Total estimated population was 482 in Angoon in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	400	465	638	572	497	482

Source: USDA Forest Service 1997a; U.S. Census Bureau 2001; Alaska DOL 2007a

The Chatham School District and commercial fishing provide the majority of employment for Angoon. Approximately 10 percent of Angoon (72 residents) held commercial fishing permits (94 permits) in 2005. These permits were primarily used for hand-trolling for king and coho salmon. State and Federal grants recently funded a new shellfish farm in the area. Logging on Prince of Wales Island provides occasional jobs (Alaska DCED 2002).

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. Approximately 13 percent of the labor force in Angoon was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $29,861, compared to a regional median of $44,118 (Alaska DCED 2002).

Employment by Industry	Number	Percent of Total
Agriculture, Forestry, Fishing & Hunting, Mining	10	5

Source: Alaska DCED 2002

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community. Angoon is part of the Chatham Strait community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in of the planning record for this EIS. The non-federal government, wood products, and service sectors were the major employers in the Chatham Strait community group in 1999, accounting for 49, 18, and 17 percent of total employment, respectively. The wood products employment was entirely in the logging sector.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Angoon in their local day-to-day work, recreational, and subsistence activities is shown in Figure 3.23-2. This area contains 1,083,231 acres of National Forest System land (among other land ownerships). Table 3.23-9 shows how the lands within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3 of this document.

Development LUDs presently account for 32 percent of the total acreage within the Angoon community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 through 3. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 27 percent under Alternative 5 (No Action) to 55 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-9). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 40 percent and 42 percent under Alternatives 4 and 7, respectively, compared to 32 percent under Alternative 5.

Figure 3.23-2
Angoon's Community Use Area

Total	**1,083,231**	**1,083,231**	**1,083,231**	**1,083,231**	**1,083,231**	**1,083,231**	**1,083,231**

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

Total suitable acres would range from 2 percent of the Angoon community use area under Alternative 1 to 12 percent under Alternative 7, compared to 8 percent under Alternative 5 (No Action) and Alternative 6 (Proposed Action).

Economy

Angoon is a traditional native community. Commercial fishing and subsistence use are the primary factors influencing Angoon. For subsistence use, Admiralty and Catherine Islands are especially important to Angoon. All of the National Forest System land within the Angoon community use area on Admiralty Island would be maintained in their current condition under all alternatives. Commercial fishing would not be affected under any of the alternatives.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 52 percent of the total edible pounds of subsistence resources harvested by Angoon households (Kruse and Frazier 1988). Marine resources (fish and marine invertebrates), primarily salmon, accounted for the majority (81 percent) of per capita subsistence harvest in Angoon in 1996 (ADF&G 2006).

The 1988 TRUCS study found that deer accounted for 30 percent of the total edible pounds of subsistence resources harvested by Angoon households (Kruse and Frazier 1988). Deer accounted for 15 percent of per capita subsistence harvest by Angoon residents in 1996 (ADF&G 2006).

The WAAs used by Angoon residents for hunting deer lie within Game Management Unit (GMU) 4. Deer harvest in GMU 4 is considered very high relative to other areas of Southeast Alaska, which is indicative of relatively high deer populations (ADF&G 2005). Over 1997-2004, there has been no significant trend in the number of deer harvested or in the number of hunters (ADF&G 2005). However, as shown above, from 1990 to 2005 Angoon's human population has been on a declining trend and is currently 22 percent below 1990 levels.

Angoon residents take the majority (59 percent) of their deer from three WAAs on Admiralty Island (4042, 4054, and 4055). As shown in Table 3.23-10, these three WAAs will not be affected by any of the alternatives. The next two WAAs in importance contribute 20 percent of Angoon's deer harvest and would each be affected under the alternatives, with the greatest effects occurring under Alternatives 4 and 7.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that all of the alternatives should be able to provide habitat capability for deer hunted by Angoon residents, all rural hunters, and all hunters within the WAAs where Angoon hunters derive most of their deer harvest. Because Alternative 7, the most timber-intensive alternative in this EIS, is similar to Alternative 2 in the 1997 Forest Plan EIS, all alternatives in this EIS should be able to provide habitat capability for deer hunted by Angoon residents, as well as for all deer hunted within the WAAs.

Table 3.23-10
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Angoon Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability							
WAA	Angoon Residents	All Rural Hunters	All Hunters	2005	Alt 1	Alt 2	Alt 3	Alt 4	Alt 5	Alt 6	Alt 7

3315	20	85	107	83	82	75	75	71	74	74	69
3308	16	98	158	66	64	59	57	53	56	57	51

*Calculated based on harvest where location is known.

In summary, use of most subsistence resources (fish and marine invertebrates) by Angoon residents is not expected to be affected under any of the alternatives. In addition, subsistence use of deer by Angoon households is unlikely to be directly affected by any of the alternatives as the areas most heavily used by Angoon residents (on Admiralty Island) will be essentially unmodified under all alternatives. It is possible, however, that the more timber-intensive alternatives, especially Alternatives 4 and 7, would create increased competition for deer within Angoon's subsistence use areas if hunters from other communities are displaced due to timber harvest activity. These impacts are estimated to be minor based on the limited accessibility of these areas to non-local hunters. The three WAAs of highest importance to Angoon hunters, which occur on Admiralty Island, have very low road densities. Open and total road densities range from 0 to 0.1 mile per square mile (for all ownerships combined).and road densities in these WAAs are expected to increase insiginificantly in the future under any of the alternatives. Although the WAAs of importance to Angoon across Chatham Strait on Chichagof, Baranof, and Catherine Islands have considerably higher road densities, these roads are generally isolated and not connected to a community road system.

Coffman Cove

Coffman Cove is located on northeast Prince of Wales Island. Settlement of Coffman Cove began in 1956 with development of a logging camp. A road connecting Coffman Cove to the larger community of Craig was built in the 1980s. Two scheduled airlines serve the community from Ketchikan. The population of Coffman Cove shows little change between 1980 and 2000. According to the 2000 Census, Coffman Cove had a 2000 population of 199, with Alaska Natives comprising 3 percent of the total (U.S. Census Bureau 2001). The population decreased by 22 percent between 2000 and 2005, with an estimated population of 156 in 2005. Total estimated population was 162 in Coffman Cove in 2006 (Alaska DOL 2007a).

Year	1980	1990	2000	2005	2006
Population	193	186	199	156	162

Source: USDA Forest Service 1997a; U.S. Census Bureau 2001; Alaska DOL 2007a

The logging industry and the local school system provide the majority of employment for Coffman Cove. One of the major log transfer sites on Prince of Wales Island is located at Coffman Cove. Oyster farming and commercial fishing also occur in the area. The city is conducting a study of the feasibility of creating a commercial/ industrial complex (Alaska DCED 2006). Roundtrip service is currently (summer 2006) provided to Coffman Cove from Wrangell and Petersburg by the Inter-Island Ferry Authority.

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. Approximately 11 percent of the labor force in Coffman Cove was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $43,750, compared to a regional median of $44,118 (Alaska DCED 2002).

Source: Alaska DCED 2002

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Coffman Cove is located in the Thorne Bay Ranger District and is part of the North Prince of Wales community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record for this EIS. Wood products employment in the North Prince of Wales community group declined by 186 jobs or 69 percent between 1990 and 1999. Wood products employment accounted for 83 jobs or 23 percent of total employment in this community group in 1999.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Coffman Cove in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-3. This area contains 1,228,787 acres of National Forest System land (among other land ownerships). Table 3.23-11 shows how the lands within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs presently account for 50 percent of the total acreage within the Coffman Cove community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 through 3. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 40

Total	**1,228,786**	**1,228,787**	**1,228,789**	**1,228,809**	**1,228,790**	**1,228,787**	**1,228,788**

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

percent under Alternative 5 (No Action) to 62 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-11). Alternatives 4 and would increase the acreage in development LUDs. Development LUDs would account for 60 percent and 72 percent under Alternatives 4 and 7, respectively, compared to 50 percent under Alternative 5.

Total suitable acres would range from 14 percent of the Coffman Cove community use area under Alternative 1 to 28 percent under Alternative 7, compared to 19 percent of the total community use area under Alternative 5 (No Action) and Alternative 6 (Proposed Action).

Economy

Coffman Cove is primarily a logging community and would, therefore, be directly affected by the amount of logging opportunities on northern Prince of Wales Island and elsewhere on the Tongass. Approximately 6.5 MMBF was under contract in the Thorne Bay Ranger District in August 2006. This volume would not be affected under any of the alternatives. These data provide an indication of potential impacts, actual impacts would depend on the volume that is under contract when the decision is implemented and whether potentially affected existing sales were cancelled as part of the decision.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 65 percent of the total edible pounds of subsistence resources harvested by Coffman Cove households (Kruse and Frazier 1988). Marine resources (fish and marine invertebrates) accounted for the majority (71 percent) of per capita subsistence harvest in the community in 1998 (ADF&G 2006).

The 1998 TRUCS study found that deer accounted for 32 percent of the total edible pounds of subsistence resources harvested by Coffman Cove households (Kruse and Frazier 1988). Deer accounted for 20 percent of per capita subsistence harvest by Coffman Cove residents in 1998 (ADF&G 2006).

Coffman Cove residents harvest deer almost entirely on Prince of Wales Island, which is included in GMU 2. Deer harvest and hunter effort in GMU 2 generally increased during 1997-2000 and subsequently declined during 2000-2004; however, no change has been noted in the average number of hunter-days required to harvest a deer (ADF&G 2005). As noted above, Coffman Cove's human population was relatively stable between 1980 and 2000, but has recently declined 22 percent below 2000 levels.

Residents of Coffman Cove harvest the majority (81 percent) of their deer from two WAAs in the eastern half of north-central Prince of Wales Island (1420 and 1421). As shown in Table 3.23-12, the Coffman Cove portion represents about one-third of the total harvest and about one-half of the rural hunter harvest in these WAAs. About 36 percent of the combined harvest in these WAAs is by non-rural hunters, suggesting that there is a harvest buffer that could be restricted, if necessary, before restrictions are placed on rural harvests.

WAAs 1420 and 1421 occur in an area with substantial past harvest and, therefore, deer habitat capabilities are currently estimated to be considerably below 1954 levels (Table 3.23-12). Under each of the alternatives, additional harvest would occur that would reduce habitat capabilities after 100+ years to 36 to 43 percent of 1954 levels in WAA 1420 and 55-66 percent in WAA 1421.

Table 3.23-12
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Coffman Cove Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability							
WAA	Coffman Cove Residents	All Rural Hunters	All Hunters	2005	Alt 1	Alt 2	Alt 3	Alt 4	Alt 5	Alt 6	Alt 7
1420	87	151	231	52	43	42	40	39	40	40	36
1421	22	47	76	74	66	64	64	64	63	63	55

*Calculated based on harvest where location is known.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide sufficient habitat capability over the long term for deer hunted by Coffman Cove residents. However, it concluded that demand would exceed the capability of the habitat to produce deer populations sufficient to avoid effects on hunter success for all rural hunters in the long term and for all hunters in both the short and long terms.

In summary, use of most subsistence resources by Coffman Cove residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives. However, subsistence use of deer may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1. The risks of this occurring are greatest under Alternative 7 because of its general lack of Non-development LUDs within the Coffman Cove use area, and lower under the other six alternatives. The risk of hunting restrictions would be reduced somewhat, through more intensive management (e.g., thinning) of the existing and future closed-canopy, young-growth forests in this area. Indirect effects associated with increased competition for deer within Coffman Cove's subsistence use areas could also occur under all alternatives due to displacement of hunters from other communities due to timber harvest activity. Additional road development under the alternatives would improve access but may increase competition with other non-local hunters. The level of road development is already relatively high in these WAAs. Existing open road densities are 1.1 and 0.7 miles per square mile and existing total road densities are 1.8 and 1.3 miles per square mile in WAAs 1420 and 1421, respectively (for all ownerships combined). Long-term (100+ years) road development would vary by alternative and would result in estimated maximum total road densities ranging from 1.6 to 2.0 miles per square mile in these WAAs under Alternative 1, to 2.0 to 2.2 miles per square mile in these WAAs under Alternative 7 (for all ownerships combined).

Craig

Craig is situated on a small island connected to the west coast of Prince of Wales Island by a causeway. Craig is located approximately 56 air miles northwest of Ketchikan and 6 and 23 road miles from Klawock and Hydaburg, respectively. A floatplane dock and heliport are maintained in Craig, and the State ferry serves Hollis 30 miles away enabling transportation of passengers, cargo, and vehicles.

Tlingit fish camps and seasonal villages originally occupied the present location of Craig. It was named for its contemporary founder, Craig Miller, who in 1907, with the help of local Haidas, established a saltery at Fish Egg Island.

The Forest Service established a permanent ranger station here around 1919. The city of Craig was incorporated in 1922 as a second-class city under the laws of the territory of Alaska and became a first-class city in 1973. Shaan-Seet Inc. (the village corporation established under the Alaska Native Claims Settlement Act of 1971) received an interim conveyance of 20,852 acres in 1979 (ADF&G 1994).

The population of Craig more than tripled between 1970 and 1990. According to the 2000 Census, Craig had a 2000 population of 1,397, with Alaska Natives comprising 22 percent of the total (U.S. Census Bureau 2001). The total population was 10 percent higher in 2000 than in 1990. The population decreased by an estimated 301 residents or 22 percent from 2000 to 2005. Total estimated population was 1,105 in Craig in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	272	527	1,260	1,397	1,096	1,105

Source: USDA Forest Service 1997a; U.S. Census Bureau 2001; Alaska DOL 2007a

The Craig economy is primarily based on the fishing and timber industry with commercial fishing, fish processing, logging, sawmill operations, government and commercial services providing the majority of employment. Estimated gross fishing earnings of local residents exceeded $2.6 million in 2000. Columbia Ward Fisheries, a fish buying station, and a major cold storage plant are located in Craig and 200 residents hold commercial fishing permits. Shan-Seet Village Corporation timber operations is a major employer of local residents. Craig's increased role as a service and transportation center for the Prince of Wales Island communities has largely been responsible for its growth (Alaska DCED 2002). The Viking Lumber sawmill is located near Craig. According to the 2006 mill survey conducted for the USDA Forest Service, this mill, which has an installed production capacity of 80 MMBF, processed approximately 19 MMBF in 2006 and employed 42 people (Juneau Economic Development Council 2007).

W.R. Jones and Son Lumber Company is also located in Craig. This mill with an installed production capacity of 1 MMBF, processed approximately 600 MBF in 2006 and employed 4 people (Juneau Economic Development Council 2007).

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. Approximately 9 percent of the labor force in Craig was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $45,298, compared to a regional median of $44,118 (Alaska DCED 2002).

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Craig is part of the Central Prince of Wales community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record for this EIS.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Craig in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-4. This area contains 766,935 acres of National Forest System land (among other land ownerships). Table 3.23-13 shows how the land within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs presently account for 55 percent of the total acreage within the Craig community use area. Alternatives 5 and 6 would not have a significant effect on LUD allocations in the Craig community use area because the acreage in development LUD groups would remain virtually the same as under the current Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 through 3. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 39 percent under Alternative 5 (No Action) to 63 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-13). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 64 percent and 72 percent under Aternatives 4 and 7, respectively, compared to 55 percent under Alternative 5.

Total suitable acres would range from 15 percent under Alternative 1 to 28 percent under Alternative 7, compared to 20 percent of the total community use area under Alternative 5 (No Action).

Economy

Craig is primarily a commercial fishing, retail trade, and timber community. It is most likely to be affected by changes in timber employment, commercial fishing, and retail services. Viking Lumber, one of the larger remaining sawmills in the region, is located between Craig and Klawock.

Viking Lumber had 27 MMBF under contract in August 2006. Approximately 17 percent (4.6 MMBF) of this volume could be potentially affected under Alternative 1, which would maintain all Inventoried Roadless Areas on the Tongass in a natural condition and not permit timber harvest in these areas. None of the other alternatives would affect this volume. These data provide an indication of potential impacts, actual impacts would depend on the volume that is under contract when the decision is implemented and whether potentially affected existing sales were cancelled as part of the decision.

Several small timber operators produce value-added products in Craig. These value added products include music wood, cabinets, and other products. These operators process relatively low volumes of timber, but require specific species and grades to meet their needs. All alternatives should meet their needs.

Commercial fisheries employment is not likely to be affected any of the alternatives.

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 70 percent of the total edible pounds of subsistence resources harvested by Craig households (Kruse and Frazier 1988). Marine resources (fish and marine invertebrates) accounted for 67 percent of per capita subsistence harvest in Craig in 1997 (ADF&G 2006).

The 1988 TRUCS study found that deer accounted for 22 percent of the total edible pounds of subsistence resources harvested by Craig households (Kruse and Frazier 1988). Deer accounted for 19 percent of per capita subsistence harvest by Craig residents in 1997 (ADF&G 2006).

Craig residents harvest deer almost entirely on Prince of Wales and adjacent islands, which are included in GMU 2. Deer harvest and hunter effort in GMU 2 generally increased during 1997-2000 and subsequently declined during 2000-2004; however, no change has been noted in the average number of hunter-days required to harvest a deer (ADF&G 2005). As noted above, the human population of Craig more than tripled between 1970 and 1990, continued to grow and peaked around 2000, and then declined by 21 percent as of 2005.

Deer harvest by Craig residents is spread over many WAAs, but the majority (55 percent) of their deer are harvested from five WAAs in central and northern Prince of Wales Island (top five WAAs in Table 3.23-14). The Craig portion of the harvest in these five WAAs represents about one-quarter of the total harvest and about 40 percent of the rural hunter harvest (Table 3.23-14). About 30 percent of the combined harvest in these WAAs is by non-rural hunters, indicating that there is a harvest buffer that could be restricted, if necessary, before restrictions are placed on rural harvests.

Table 3.23-14
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Craig Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability

*Calculated based on harvest where location is known.

The majority of the WAAs used heavily by Craig residents are in areas with substantial past harvest and deer habitat capabilities are currently estimated to be considerably below 1954 levels (Table 3.23-14). Under each of the alternatives, additional harvest would further reduce habitat capabilities after 100+ years. Reductions would be smallest under Alternative 1 and highest under Alternative 7.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide sufficient habitat capability over the long term for deer hunted by Craig residents. However, it concluded that demand would exceed the capability of the habitat to produce deer populations sufficient to avoid effects on hunter success for all rural hunters in the long term and for all hunters in both the short and long terms.

In summary, use of most subsistence resources by Craig residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives. However, subsistence use of deer may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1. The risks of this occurring are greatest under Alternative 7 because of its general lack of non-development LUDs throughout most of Prince of Wales Island, and second highest under Alternative 4 because of its lower use of non-development LUDs than the other alternatives. Alternatives 1, 2, and 3 would have the lowest risk and Alternatives 5 and 6 would be intermediate. The risk of hunting restrictions would be reduced somewhat, through more intensive management (e.g., thinning) of the existing and future closed-canopy, young-growth forests in this area. Indirect effects associated with increased competition for deer within Craig's subsistence use areas could also occur under all alternatives due to displacement of hunters from other communities due to timber harvest activity. Additional road development under the alternatives would improve access but may increase competition with other non-local hunters. The level of road development is already relatively high in these WAAs. Existing open road densities range from 0.6 to 1.9 miles per square mile and existing total road densities range from 1.2 to 1.9 miles per square mile in the five most important WAAs for Craig deer harvest (for all ownerships combined). Long-term (100+ years) road development would vary by alternative and would result in estimated maximum total road densities ranging from 1.3 to 2.8 miles per square mile in these WAAs under Alternative 1, to 1.6 to 3.0 miles per square mile in these WAAs under Alternative 7 (for all ownerships combined).

Edna Bay

Edna Bay is located on southeast Kosciusko Island, west of Prince of Wales Island, and north of Sea Otter Sound. Originally, Tlingit Indians from west Prince of Wales Island used Edna Bay on a seasonal basis. In 1943, a logging camp was established when the demand for aircraft-quality spruce was high. The camp closed in the late 1960s and the buildings were burned and the site cleaned. In 1977, the State selected part of the Tongass National Forest at Edna Bay, with the U.S. Forest Service reserving two administrative sites. In 1982, the State sold several lots around Edna Bay to private landowners. A small community developed as families, mainly those involved in commercial fishing, moved to Edna Bay. A school was constructed and a road connecting dispersed segments of the community was completed (ADF&G 1994).

Edna Bay remains an unincorporated city. The community has a local Fish and Game Advisory Committee and has shown a strong commitment to protecting local commercial fishing and subsistence resources (ADF&G 1994). Edna Bay is accessible by water or by float plane from Ketchikan. Most households own skiffs for transportation around the bay and to other near shore areas not accessible by road (ADF&G 1994).

Edna Bay's population fluctuated a great deal between 1970 and 1990. The population in 2000 was very similar to that identified in 1990. According to the 2000 Census, Edna Bay had a 2000 population of 49, with no Alaska Native population (U.S. Census Bureau 2001). The population declined by 16 percent—an estimated eight people—between 2000 and 2005, with an estimated population of 41 in 2005. Total estimated population was also 41 in Edna Bay in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	112	6	86	49	41	41

Source: USDA Forest Service 1997a; U.S. Census Bureau 2001; Alaska DOL 2007a

The majority of employment in Edna Bay is provided by a local sawmill, commercial fishing, and the local school district. Thirteen residents hold commercial fishing licences, primarily used for power trolling. During the summer, a fish buyer is also located in the bay (Alaska DCED 2002).

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. This data is an extrapolation based on information from a sample of residents. Because the sample size was small, the extrapolation may not be exact, but it should provide a general indication of distribution of employment. The potential work force was estimated to be 35 people and total employment estimated to be 18. While no adults in Edna Bay were identified as unemployed and seeking work in 2000, 49 percent of the population was identified as not employed and not seeking work. Median household income was $44,583, compared to a regional median of $44,118 (Alaska DCED 2002).

Source: Alaska DCED 2002

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community. Edna Bay is part of the North Prince of Wales community group (see Table 3.23-6). Detailed employment data are available for this community group for 1990, 1995, and 2000 in the planning record for this EIS. Wood products employment in the North Prince of Wales community group declined by 186 jobs or 69 percent between 1990 and 1999. Wood products employment accounted for 83 jobs or 23 percent of total employment in this community group in 1999.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Edna Bay in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-5. This area contains 665,386 acres of National Forest System land (among other land ownerships).

Development LUDs presently account for 49 percent of the total acreage within the Edna Bay community use area. Table 3.23-15 shows how the lands within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly

Natural LUDs would increase under Alternatives 1 through 3. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 46 percent under Alternative 5 (No Action) to 67 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-15). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 54 percent and 62 percent under Alternatives 4 and 7, respectively, compared to 49 percent under Alternative 5.

Total suitable acres would range from 16 percent under Alternative 1 to 25 percent under Alternative 7, compared to 19 percent of the total community use area under Alternative 5 (No Action).

Economy

Edna Bay is primarily a commercial fishing and subsistence community. Commercial fishing is not expected to be significantly affected under any of the alternatives.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources accounted for 59 percent of the total edible pounds of subsistence resources harvested by Edna Bay households based on the 1998 TRUCS study (Kruse and Frazier 1988). Marine resources (fish and marine invertebrates) accounted for 69 percent of per capita subsistence harvest in Edna Bay in 1998 (ADF&G 2006).

The 1988 TRUCS study found that deer accounted for 21 percent of the total edible pounds of subsistence resources harvested by Edna Bay households (Kruse and Frazier 1988). Deer accounted for 23 percent of per capita subsistence harvest by Edna Bay residents in 1998 (ADF&G 2006).

Three WAAs have been identified as most important to Edna Bay residents for deer harvest: WAA 1525, covering Kosciusko Island; WAA 1003, covering Heceta Island; and WAA 3315, covering Catherine Island and adjacent parts of Baranof Island. Over 75 percent of Edna Bay's harvest is derived from the first two WAAs, which are included in GMU 2. Deer harvest and hunter effort in GMU 2 generally increased during 1997-2000 and subsequently declined during 2000-2004; however, no change has been noted in the average number of hunter-days required to harvest a deer (ADF&G 2005). As noted above, Edna Bay's human population has fluctuated considerably from 1970 to 1990 and has declined since then, with the 2005 population at less than half the 1990 level.

Residents of Edna Bay are responsible for the majority (62 percent) of the deer harvested on Kosciusko Island (WAA 1525), but only a small portion of the deer harvested on Heceta Island and in other WAAs. As shown in Table 3.23-16, the Edna Bay portion represents about 14 percent of the total harvest and about 29 percent of the rural hunter harvest in these WAAs. About 43 percent of the combined harvest in these WAAs is by non-rural hunters, suggesting that there is a harvest buffer that could be restricted, if necessary, before restrictions are placed on rural harvests.

Table 3.23-16
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Edna Bay Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability							
WAA	Edna Bay Residents	All Rural Hunters	All Hunters	2005	Alt 1	Alt 2	Alt 3	Alt 4	Alt 5	Alt 6	Alt 7
1525	8	11	13	51	48	47	46	46	46	46	43
1003	4	31	61	66	54	53	53	49	51	52	47

*Calculated based on harvest where location is known.

The two WAAs used heavily by Edna Bay residents are in areas with substantial past harvest and deer habitat capabilities are currently estimated to be considerably below 1954 levels (Table 3.23-16). Under each of the alternatives, additional harvest would further reduce habitat capabilities. Reductions would be smallest under Alternatives 1 and 2 and greatest under Alternative 7.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that all of the alternatives should be able to provide habitat capability for deer hunted by Edna Bay residents, all rural hunters, and all hunters, within the WAAs where Edna Bay hunters derive most of their deer harvest. Because Alternative 7, the most timber-intensive alternative in this EIS, is similar to Alternative 2 in the 1997 Forest Plan EIS, the 1997 analysis indicates that all alternatives in this EIS should be able to provide habitat capability for deer hunted by Edna Bay residents, as well as for all deer hunted within the WAA's.

In summary, use of most subsistence resources by Edna Bay residents (fish and marine resources) is not expected to be affected under any of the alternatives. In addition, subsistence use of deer by Edna Bay households is unlikely to be directly affected by any of the alternatives, as the area most heavily used by Edna Bay residents appears to have a low current rate of harvest by local hunters and all hunters combined and it is unlikely that demand will increase sufficiently in the future to result in a direct effect. Future young-growth management (e.g., thinning) would further reduce the potential for effects on local hunters. It is possible, however, that additional timber harvest throughout Prince of Wales and adjacent islands would create increased competition for deer within Edna Bay's subsistence use areas if hunters from other communities are displaced due to timber harvest activity. These impacts are estimated to be relatively minor based on the limited accessibility of these island areas to non-local hunters. The two WAAs of highest importance to Edna Bay hunters have relatively high existing road densities. Existing open road densities range from 1.1 to 1.5 miles per square mile and total road densities range from 2.0 to 2.3 miles per square mile (for all ownerships combined). However, these road systems are not connected to any community road systems outside of Edna Bay. Long-term (100+ years) road development would vary by alternative and would result in estimated maximum total road densities ranging from 2.4 to 2.5 miles per square mile in these WAAs under Alternative 1, to 2.7 to 2.8 miles per square mile in these WAAs under Alternative 7 (for all ownerships combined).

Elfin Cove

Elfin Cove is a small fishing town located on northwest Chichagof Island. Prior to its development as a community, Native Tlingit groups, now based largely in Hoonah, used the Elfin Cove area for hunting, fishing, and gathering, as well as a safe harbor. According to the 2000 Census, Elfin Cove had a 2000 population of 32, none of whom were Alaska Natives (U.S. Census Bureau 2001).

A fish buyer established a business here in 1927. The opening of a cold storage plant at Pelican, less than 20 miles from Elfin Cove in Lisianski Inlet, meant that fish no longer had to be hauled all the way to Juneau. Today, the cove still serves as a key stopover and supply center for fishermen and the year-round community is made up largely of fishing households. In the 1980s, a school was completed that also functions as a community center.

Elfin Cove is an unincorporated community. The community has a local Fish and Game Advisory Committee and is accessible by floatplane from Juneau. Elfin Cove's population, which fluctuated between 1970 and 1990, was 25 people or 44 percent lower than it was in 1990. The population remained fairly stable between 2000 and 2005, with an estimated decrease in total population of three people. Total estimated population was 25 in Elfin Cove in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	49	28	57	32	29	25

Source: USDA Forest Service 1997a; U.S. Census Bureau 2001; Alaska DOL 2007a

The economy of Elfin Cove is highly seasonal and primarily based on the fishing industry. It is a fish buying and supply center for fishermen and residents participate in commercial fishing, sport fishing and charter services. Eighty percent of the population (26 residents) holds commercial fishing permits. Seasonal employment is also provided by summer lodges and local retail businesses (Alaska DCED 2006).

A recent study of nature-based tourism in Southeast Alaska found that although Elfin Cove had been dependent on the commercial fishing industry for decades, the focus of the town's economy had shifted toward tourism and sportfishing (Dugan et al. 2006). This study also found that the community's population ranged from 12 in the winter to 200 in the summer, with much of the summer increase associated with employment in nine sport fishing lodges. The study estimated that 54 people, mostly non-residents, were employed by these lodges during the summer. Small cruise ships, mostly carrying 60 to 70 passengers, dock at Elfin Cove, with 30 dockings in 2005 (Dugan et al. 2006).

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. This data is an extrapolation based on information from a sample of residents. Because the sample size was small, the extrapolation may not be exact, but it should provide a general indication of distribution of employment. Approximately 23 percent of the labor force in Elfin Cove was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $33,750, compared to a regional median of $44,118 (Alaska DCED 2002).

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Elfin Cove is part of the North Chichagof community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record for this EIS. Manufacturing and non-federal government were the major employers in the North Chichagof community group in 1999, accounting for 34 and 30 percent of total employment, respectively. Logging and seafood processing accounted for 24 and 10 percent of total employment, respectively.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Elfin Cove in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-6. This area contains 357,385 acres of National Forest System land (among other land ownerships). Table 3.23-17 shows how the land within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

The proposed alternatives would not have a significant effect on existing LUD allocations in the Elfin Cove community use area because the acreage in development LUDs would remain essentially the same as under the existing Forest Plan under all of the alternatives, with a very slight increase in development LUDs and suitable acres under Alternatives 4 and 7.

Economy

Commercial fishing, recreation and tourism, and subsistence use are important to Elfin Cove. The acreage in the Elfin Cove community use area is either Wilderness or Mostly Natural LUD allocations. Local timber production is not a significant part of the local economy. Commercial fishing is not expected to be significantly affected under any of the alternatives. Tourism, especially sportfishing, has recently become more important to Elfin Cove. A number of lodges operate out of the community. Recreation and tourism based on sportfishing is expected to increase by the same amount under all of the alternatives.

Icy Strait, northwest Chichagof Island, and Yakobi Island are the most important areas in terms of subsistence use to Elfin Cove. Portions of these areas are legislatively withdrawn from timber harvest as either Wilderness or LUD II and would be maintained in their current condition under all alternatives. The remaining area is allocated to Mostly Natural LUDs and would continue to be either mostly natural or further restricted by re-allocation as Recommended Wilderness or LUD II.

Figure 3.23-6

Intensive Development	0	1	5	5,015	18	5	5,015
Total	**357,385**	**357,385**	**357,385**	**357,385**	**357,385**	**357,385**	**357,385**

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources accounted for 63 percent of the total edible pounds of subsistence resources harvested by Elfin Cove households based on the 1988 TRUCS study (Kruse and Frazier 1988). Marine resources (fish and marine invertebrates) accounted for 62 percent of per capita subsistence harvest in Elfin Cove in 1987 (ADF&G 2006).

The 1988 TRUCS study found that deer accounted for 27 percent of the total edible pounds of subsistence resources harvested by Elfin Cove households (Kruse and Frazier 1988). Deer accounted for 28 percent of per capita subsistence harvest by Elfin Cove residents in 1987 (ADF&G 2006).

The WAAs used by Elfin Cove residents for hunting deer lie within Game Management Unit (GMU) 4. Deer harvest in GMU 4 is considered very high relative to other areas of Southeast Alaska, which is indicative of relatively high deer populations (ADF&G 2005). Over 1997-2004, there has been no significant trend in the number of deer harvested or in the number of hunters (ADF&G 2005). However, as shown above, although from 1970 to 2005 the number of residents in Elfin Cove has fluctuated, the number in 2005 is 51 percent of the peak in 1990.

Elfin Cove residents take the majority (74 percent) of their deer from two WAAs on northwestern Chichagof Island (3417 and 3421). As shown in Table 3.23-18, these WAAs would not be affected by any of the alternatives because they are in wilderness, LUD II areas, or are in other Non-development LUDs. The next two WAAs in importance are also in the same area and also would not be affected by any of the alternatives because of their LUDs.

Table 3.23-18
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Elfin Cove Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability							
WAA	**Elfin Cove Residents**	**All Rural Hunters**	**All Hunters**	**2005**	**Alt 1**	**Alt 2**	**Alt 3**	**Alt 4**	**Alt 5**	**Alt 6**	**Alt 7**
3421	14	29	36	100	100	100	100	100	100	100	100
3417	7	100	159	100	100	100	100	100	100	100	100

*Calculated based on harvest where location is known.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that all of the alternatives should be able to provide habitat capability for deer hunted by Elfin Cove residents, all rural hunters, and all hunters within the WAAs where Elfin Cove hunters derive most of their deer harvest in the short term. In the long term, sufficient habitat would be provided for Elfin Cove residents and all rural hunters, but not for all hunters. However, the predicted deficit for all hunters in the long term would be a natural condition and not due to timber harvest.

In summary, use of most subsistence resources (fish and marine invertebrates) by Elfin Cove residents is not expected to be affected under any of the alternatives. In addition, subsistence use of deer by Elfin Cove households would not be directly affected by any of the alternatives as the areas most heavily used by Elfin Cove residents are in Non-development LUDs. It is also unlikely that Elfin Cove residents would be affected by increased competition or access because of the limited access and the lack of activities under the alternatives in this area.

Gustavus

Gustavus is located in northern Southeast Alaska on the north shore of Icy Straits, east of the entrance to Glacier Bay. Prior to the founding of the present community, Huna Tlingit used the land and resources in the immediate vicinity of the community site. Use of a salmon camp near the mouth of the Salmon River was noted by early Gustavus settlers; however, after a short period of settlement by the new community, the Huna Tlingit generally discontinued use of the camp (ADF&G 1994). According to the 2000 Census, Gustavus had a 2000 population of 429, with Alaska Natives comprising 44 percent of the total (U.S. Census Bureau 2001).

Gustavus was settled and named "Strawberry Point" in 1914 by a small group of immigrants from the lower 48 planning to develop the land as agricultural homesteads. World War II brought development to Gustavus in the form of an airstrip and Federal Aviation Administration communications facilities. Nearby Glacier Bay National Monument was established in 1925 (ADF&G 1994).

The population of Gustavus, which increased considerably between 1970 and 1990, increased by 66 percent between 1990 and 2000 and continued to increase in the first part of this decade, although at a much slower rate with an estimated total population of 459 in 2005. Total estimated population was 441 in Gustavus in 2006 (Alaska DOL 2007a).

Year	**1970**	**1980**	**1990**	**2000**	**2005**	**2006**
Population	64	98	258	429	459	441

Source: USDA Forest Service 1997a, U.S. Census Bureau 2001; Alaska DOL 2007a

The economy of Gustavus is seasonal, at least partly due to its proximity to Glacier Bay National Park. The park and its lodge attract tourists and recreation enthusiasts during the summer months and there is also a commercial fishing industry. The lodge, airport, school, small businesses, and the Park Service are primary employers of local residents (Alaska DCED 2002).

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. Approximately 14 percent of the labor force in Gustavus was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $34,766, compared to a regional median of $44,118 (Alaska DCED 2002).

Employment by Industry	**Number**	**Percent of Total**

Total Employment	**190**	**100**

Source: Alaska DCED 2002

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Gustavus is part of the Gustavus community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record for this EIS.

The services and Federal government sectors were the largest employers in the Gustavus community group in 1999, accounting for 40 and 36 percent of total employment, respectively. There is no wood products employment in this community. Recreation and tourism-related activities (lodging, restaurants, and recreation services) accounted for 40 percent of total employment in 1999.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Gustavus in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-7. This area contains 480,541 acres of National Forest System land (among other land ownerships). Table 3.23-19 shows how the land within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs presently account for 35 percent of the total acreage within the Gustavus community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 through 3. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 59 percent under Alternative 5 (No Action) to 89 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-19). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 46 percent and 56 percent under Alternatives 4 and 7, respectively, compared to 35 percent under Alternative 5.

Total suitable acres would range from 2 percent under Alternative 1 to 16 percent under Alternative 7, compared to 7 percent of the total community use area under Alternative 5 (No Action) and Alternative 6 (Proposed Action).

Economy

Gustavus is a small community located near Glacier Bay National Park. Recreation and tourism are important to Gustavus, especially in relation to use of the National Park. Commercial fishing and subsistence use are also important to the community.

Commercial fishing is not expected to be significantly affected by Forest Service activities under any of the alternatives.

Figure 3.23-7
Gustavus' Community Use Area

Total	**480,541**	**480,541**	**480,541**	**480,537**	**480,541**	**480,541**	**480,541**

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. Marine resources (fish and marine invertebrates) accounted for 69 percent of per capita subsistence harvest in Gustavus in 1987.

The 1988 TRUCS study found that deer accounted for 70 percent of the total edible pounds of subsistence resources harvested by Gustavus households (Kruse and Frazier 1988). Deer accounted for 27 percent of per capita subsistence harvest by Gustavus residents in 1987 (ADF&G 2006).

The primary WAAs used by Gustavus residents for hunting deer lie within Game Management Unit (GMU) 4. Deer harvest in GMU 4 is considered very high relative to other areas of Southeast Alaska, which is indicative of relatively high deer populations (ADF&G 2005). Over 1997-2004, there has been no significant trend in the number of deer harvested or in the number of hunters (ADF&G 2005). However, as shown above, the number of residents in Gustavus has increased steadily from 1970 to 2005, and the 2005 population is seven times the size it was in 1970.

Gustavus residents take the majority (80 percent) of their deer from two WAAs on northern Chichagof Island and Pleasant, Lemesurier, and Inian Islands (4256 and 4222). As shown in Table 3.23-20, WAA 4256, which provides over half of Gustavus' harvest, would not be affected by any of the alternatives because it is in wilderness. WAA 4222 would be affected by timber harvest, especially by Alternatives 4 and 7.

Table 3.23-20
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Gustavus Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability							
WAA	Gustavus Residents	All Rural Hunters	All Hunters	2005	Alt 1	Alt 2	Alt 3	Alt 4	Alt 5	Alt 6	Alt 7
4256	26	30	45	100	100	100	100	100	100	100	100
4222	12	45	64	97	96	95	94	86	94	94	86

*Calculated based on harvest where location is known.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that all of the alternatives should be able to provide habitat capability for deer hunted by Gustavus residents, all rural hunters, and all hunters within the WAAs where Gustavus hunters derive most of their deer harvest in the short term. In the long term, sufficient habitat would be provided for Gustavus residents and all rural hunters, but not for all hunters. The predicted deficit for all hunters in the long term would be a natural condition, but would occur earlier with timber harvest in the area.

In summary, use of most subsistence resources (fish and marine invertebrates) by Gustavus residents is not expected to be affected under any of the alternatives. In addition, subsistence use of deer by Gustavus households may be slightly affected to the point that some restriction in hunting by non-rural hunters might be necessary over the long term. It is also unlikely that Gustavus residents would be affected by increased competition or access because of the limited access and the lack of activities under the alternatives in this area.

Haines

Haines is located in the northern portion of Southeast Alaska, near the north end of Lynn Canal on the Chilkat Peninsula. Haines is one of three Southeast communities connected by road to Canada. According to the 2000 Census, Haines had a 2000 population of 2,292, with Alaska Natives comprising 11 percent of the total (U.S. Census Bureau 2001). Haines Borough includes the city of Haines, which had a 2000 population of 1,811, and several surrounding communities. These communities include Lutak, just north of Haines, which had a population of 39 in 2000 and Mosquito Lake, historically Chilkat Tlingit territory, which was home to 221 residents in 2000, 5 percent identified as Alaska Natives. Covenant Life, a religious community, had 102 residents in 2000.

The Haines area was originally settled by the Chilkat Tlingits. The Chilkat Tlingits are now considered as two groups: the Chilkats of the Chilkat River, with Klukwan being the major population center, and the Chilkoots living in and near Haines. Haines itself was a trade center and mission site (ADF&G 1994). Klukwan, a Chilkat Indian Village near the Chilkat River and 22 miles north of Haines, had a population of 139 in 2000. The village is known for its woven artwork of cedar bark and mountain goat hair. The area is host to the largest concentration of bald eagles in the world during the fall and winter at the nearby Chilkat Bald Eagle Reserve.

Settlement did not concentrate in Haines until the late 1800s. The commercial fishing industry located several canneries in the Chilkat Inlet area near Haines beginning in 1882; the Klondike gold rush brought thousands of prospectors to the town in the late 1890s; and the Dalton Trail was established as an open access route into the interior in the 1890s. Haines incorporated as a city in 1910 and as a third class borough in 1968 (ADF&G 1994).

Haines is a major trans-shipment point because of its ice-free, deep-water port and dock, and year-round road access to Canada and Interior Alaska on the Alaska Highway. It is a northern terminus of the Alaska Marine Highway System and a hub for transportation to and from Southeast Alaska (Alaska DCED 2006).

The population of Haines has increased steadily since 1970. In the last decade, between 1990 and 2000, it increased 46 percent (U.S. Census Bureau 2001). The estimated total population decreased by about 16 percent between 2000 and 2005. Total estimated population was 1,492 in Haines in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	463	993	1,238	1,811	1,525	1,492

Source: USDA Forest Service 1997a; U.S. Census Bureau 2001; Alaska DOL 2007a

The economy of Haines is highly seasonal. Commercial fishing, tourism, government, and transportation are the primary employers. Estimated gross fishing earnings of local residents neared $3 million in 2000 and 128 residents hold commercial fishing permits. Haines' road connection to the State Ferry has become increasingly important to the tourism businesses. In 2001, Royal Caribbean Cruise Lines ceased serving Haines as a port of call. Today, around 45,000 cruise ship passengers visit each year (Alaska DCED 2006). Approximately 38,000 visitors arrived by land in 2005.

Employment by industry data, as compiled by the Alaska DCED from the 2000 Census, are summarized in the table below. Approximately 14 percent of the labor force in Haines was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $39,926, compared to a regional median of $44,118 (Alaska DCED 2002).

Total Employment	**772**	**100**

Source: Alaska DCED 2002

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Haines is part of the Haines community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record for this EIS.

Retail trade, services, and non-federal government were the main employers in the Haines community group in 1999, accounting for 26, 26, and 20 percent of total employment, respectively. Recreation and tourism-related activities (lodging, restaurants, and recreation services) accounted for 22 percent of total employment in 1999. Approximately 140 sawmill jobs were lost with the closure of the Chilkoot Lumber Mill in 1991. There was no wood products employment identified in the Haines community group in 1999.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of the Haines Borough in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-8. This area contains 232,496 acres of National Forest System land (among other land ownerships). Table 3.23-21 shows how the land within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Figure 3.23-8
Haines' Community Use Area

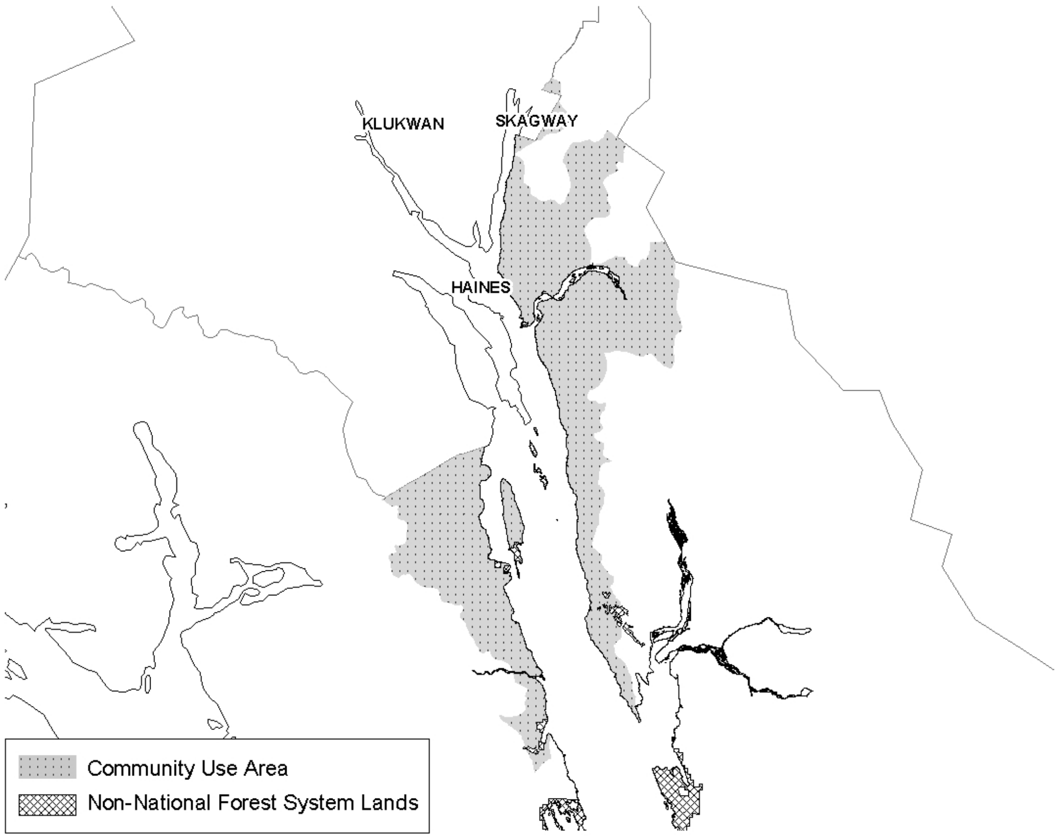

Table 3.23-21
LUD Groups in Haines' Community Use Area by Alternative

	Alternative						
	1	**2**	**3**	**4**	**5**	**6**	**7**
	Suitable National Forest System Acres for Timber Management						
Suitable Acres	233	326	2,208	8,732	6,066	5,694	9,733
LUD Groups	**Acres of National Forest System Land per LUD Group**						
Wilderness/National Monument	253	253	253	253	253	253	253
Mostly Natural	231,717	231,393	216,585	180,501	195,999	199,757	180,501
Moderate Development	527	850	15,659	51,424	36,244	32,487	51,423
Intensive Development	0	0	0	318	0	0	319
Total	**232,496**	**232,496**	**232,496**	**232,496**	**232,496**	**232,496**	**232,496**

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

Development LUDs presently account for 16 percent of the total acreage within the Haines community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 through 3. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 84 percent under Alternative 5 (No Action) to 100 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-21). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 22 percent under both of these alternatives compared to 16 percent under Alternative 5.

Total suitable acres would range from 0 under Alternatives 1 and 4 percent under Alternatives 4 and 7, compared to 3 percent of the total community use area under Alternative 5 (No Action).

Economy

Commercial fishing, recreation and tourism, and subsistence use are important to Haines. Haines has an Alaska Marine Highway System ferry terminal and provides road access into Interior Alaska. Timber harvest on State land and wood processing were historically a major sector of the Haines economy, but there was no wood products employment in Haines in 2004 (see Table 3.23-3). Mining at the Kensington Mine southeast of Haines may become a more significant employer in the future. Construction activities initiated on the mine site were halted by legal challenges and the Forest Service now anticipates the submittal of a revised plan of operations in 2008. Although the major mine support is anticipated to be located in Juneau, it is likely that some benefits would accrue to Haines.

Commercial fishing is not expected to be significantly affected under any of the alternatives. Mining, and the potential opening of the Kensington Mine, is not anticipated to be affected differently by any alternative.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 68 percent of the total edible pounds of subsistence resources harvested by Haines' households (Kruse and Frazier 1988). Marine resources (fish and marine invertebrates) accounted for 76 percent of per capita subsistence harvest in Haines in 1996.

The 1988 TRUCS study found that deer accounted for 15 percent of the total edible pounds of subsistence resources harvested by Haines households (Kruse and Frazier 1988). Deer accounted for 4 percent of per capita subsistence harvest by Haines residents in 1996 (ADF&G 2006).

Haines residents mainly harvest deer in GMU 4. Deer harvest in GMU 4 is considered very high relative to other areas of Southeast Alaska, which is indicative of relatively high deer populations (ADF&G 2005). Over 1997-2004, there has been no significant trend in the number of deer harvested or in the number of hunters (ADF&G 2005). As noted above, the human population of Haines increased steadily from 1970 through 2000, but experienced an estimated decrease of 16 percent between 2000 and 2005. Haines had an estimated population of 1,525 in 2005.

Nineteen WAAs account for about 75 percent of deer harvest by Haines residents. The two most heavily used WAAs—3418 and 3104—accounted for 12 percent and

7 percent of total deer harvest by Haines residents, respectively. As these numbers suggest, deer harvest by Haines residents is spread over a fairly wide area in GMU 4 (Table 3.23-22). As a result, Haines residents tend to comprise a relatively small share of total harvest by WAA, with two main exceptions—WAAs 1106 and 4146, which are located on Chichagof Island and Admiralty Island, respectively, and have very low levels of deer harvest. About 38 percent of the combined harvest in the 19 WAAs used by Haines residents is by non-rural hunters, suggesting that there is a harvest buffer that could be restricted, if necessary, before restrictions are placed on rural harvests.

Table 3.23-22
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Haines Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

WAA	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability

*Calculated based on harvest where location is known.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that the the 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide sufficient habitat capability for deer hunted in the Haines community use area by Haines residents, all rural hunters, and all hunters in the short term. The selected alternative should also provide sufficient habitat capability for Haines residents in the long term. Projected harvest for all rural hunters and all hunters in the Haines community use area would exceed 10 percent habitat capability, the level that the analysis assumed would provide a reasonably high level of hunter success for their effort. The Final EIS analysis concluded that at some point a restriction in hunting might be necessary.

In summary, use of most subsistence resources by Haines residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives. However, subsistence use of deer in some of the WAAs hunted by Haines residents may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1. The risks of this occurring are greatest under Alternative 7 because of its general lack of Non-Development LUDs under this alternative, and lower under the other six alternatives. The risk of hunting restrictions would be reduced somewhat, through more intensive management (e.g., thinning) of the existing and future closed-canopy, young-growth forests in this area. Indirect effects associated with increased competition for deer within Haine's subsistence use areas could also occur under all alternatives due to displacement of hunters from other communities due to timber harvest activity. Additional road development under the alternatives would improve access but may increase competition with other non-local hunters.

Hollis

Hollis is located on east Prince of Wales Island, 19 miles east of Craig. According to the 2000 Census, Hollis had a 2000 population of 139, with Alaska Natives comprising 5 percent of the total (U.S. Census Bureau 2001).

Hollis, initially settled as a mining camp at the turn of the century, developed into a logging camp in the mid-1950s. In 1960, when Thorne Bay became center of the logging industry on central Prince of Wales Island, most Hollis residents moved to Thorne Bay. In recent years, Hollis has grown as a community, due in part to an Alaska Marine Highway terminal there. Roads now connect Hollis with most other communities on Prince of Wales Island. A State land sale at Hollis in 1980 led to its present status as a permanent community (ADF&G 1994).

Viking Lumber, one of the larger sawmills presently operating in the region, is located nearby between Craig and Klawock. According to the 2006 mill survey conducted for the USDA Forest Service, this mill, which has an installed production capacity of 80 MMBF, processed approximately 19 MMBF in 2006 and employed 42 people (Juneau Economic Development Council 2007).

The population of Hollis increased by 28 people or 25 percent between 1990 and 2000. The estimated total population stayed essentially constant between 2000 and 2005, with an estimated 2 fewer people in 2005 than in 2000. Total estimated population was 156 in Hollis in 2006 (Alaska DOL 2007a).

Year	1990	2000	2005	2006
Population	111	139	137	156

Source: USDA Forest Service 1997a; U.S. Census Bureau 2001; Alaska DOL 2007a

Support services for the timber industry, the State Ferry, and the U.S. Forest Service provide the majority of employment to the residents of Hollis. While the timber industry is prevalent on the Prince of Wales Island, it does not occur directly in the Hollis Community (Alaska DCED 2002).

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. Approximately 3 percent of the labor force in Hollis was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $43,750, compared to a regional median of $44,118 (Alaska DCED 2002).

Source: Alaska DCED 2002

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Hollis is part of the Central Prince of Wales community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record for this EIS.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Hollis in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-9. This area contains 289,873 acres of National Forest System land (among other land ownerships). Table 3.23-23 shows how the land within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs presently account for 53 percent of the total acreage within the Hollis community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 through 3. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 35 percent under Alternative 5 (No Action) to 63 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-23). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 62 percent and 83 percent under Alternatives 4 and 7, respectively, compared to 53 percent under Alternative 5.

Figure 3.23-9
Hollis' Community Use Area

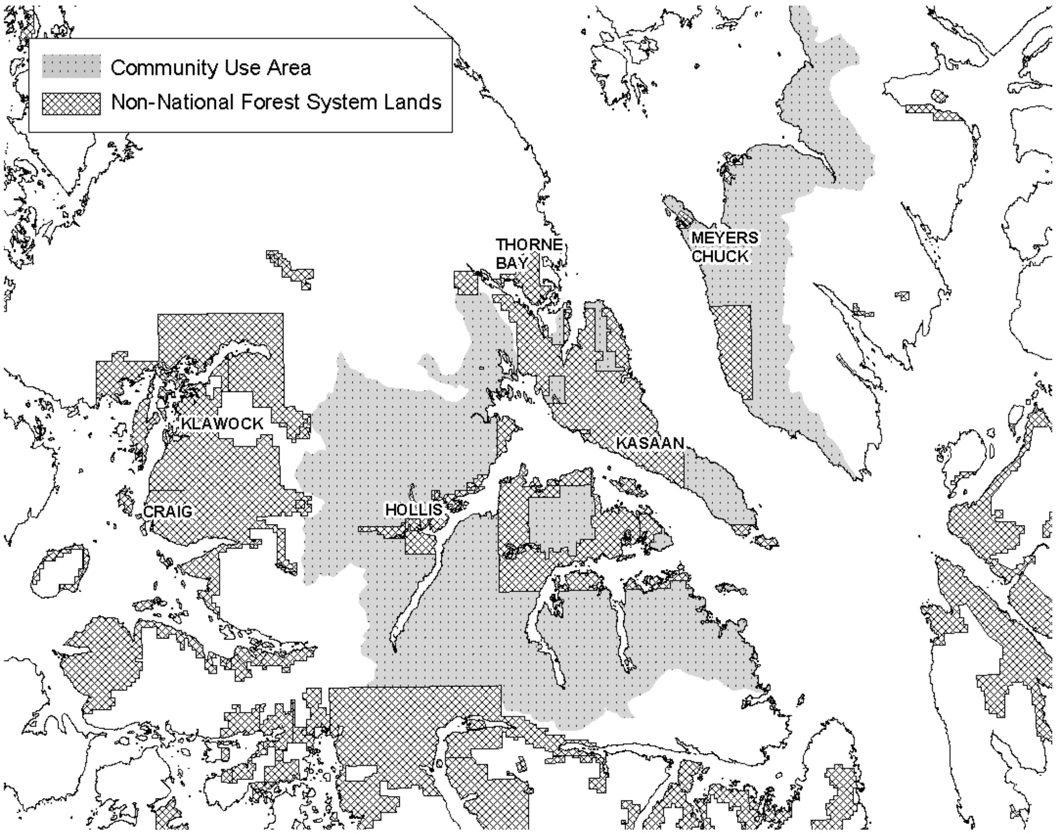

Table 3.23-23
LUD Groups in Hollis' Community Use Area by Alternative

	Alternative						
	1	**2**	**3**	**4**	**5**	**6**	**7**

Intensive Development	52,233	73,920	104,265	139,708	118,903	119,667	177,413
Total	**289,872**	**289,873**	**289,873**	**289,873**	**289,873**	**289,872**	**289,872**

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

Total suitable acres would range from 10 percent under Alternative 1 to 30 percent under Alternative 7, compared to 16 percent of the total community use area under Alternative 5 (No Action) and Alternative 6 (Proposed Action).

Economy

Hollis is the site of the Alaska Marine Highway ferry terminal that provides access to the rest of Prince of Wales Island. As such, transportation is a major component of the community's economy. Subsistence and timber also play important roles.

Viking Lumber had 27 MMBF under contract in August 2006. Approximately 17 percent (4.6 MMBF) of this volume could be potentially affected under Alternative 1, which would maintain all Inventoried Roadless Areas on the Tongass in a natural condition and not permit timber harvest in these areas. None of the other alternatives would affect this volume. These data provide an indication of potential impacts, actual impacts would depend on the volume that is under contract when the decision is implemented and whether potentially affected existing sales were cancelled as part of the decision.

The ferry terminal would continue to provide important access to Prince of Wales Island under all alternatives. Ferry access has become increasingly important to Prince of Wales Island as its population continues to grow.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 65 percent of the total edible pounds of subsistence resources harvested by Hollis households (Kruse and Frazier 1988). Marine resources (fish and marine invertebrates) accounted for 73 percent of per capita subsistence harvest in Hollis in 1998.

The 1988 TRUCS study found that deer account for 23 percent of the total edible pounds of subsistence resources harvested by Hollis households (Kruse and Frazier 1988). Deer accounted for 18 percent of the per capita subsistence harvest by Hollis residents in 1998 (ADF&G 2006).

Data were not provided for Hollis in the ADF&G deer harvest reports for 1996 to 2002. The majority of deer harvest by Hollis residents likely takes place in GMU 2—Prince of Wales Island. Deer harvest and hunter effort in GMU 2 generally increased during 1997-2000 and subsequently declined during 2000-2004; however, no change has been noted in the average number of hunter-days required to harvest a deer (ADF&G 2005). As noted above, the human population of Hollis has been relatively constant since 1990. Hollis had an estimated population of 137 residents in 2005.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that the 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide habitat capability for deer hunted in the Hollis community use area by Hollis residents and all rural hunters in both the short term and long term. Projected harvest by all hunters in the Hollis community use area would exceed 10 percent habitat capability; the level that the analysis assumed would provide a reasonably high level of hunter success for their effort, in both the short term and long term. The Final EIS analysis concluded that at some point a restriction in hunting might be necessary.

In summary, use of most subsistence resources by Hollis residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives. However, subsistence use of deer may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1. The risks of this occurring are greatest under Alternative 7, and second highest under Alternative 4 because of its lower use of Non-Development LUDs than the other alternatives. Alternatives 1, 2, and 3 would have the lowest risk and Alternatives 5 and 6 would be intermediate.

Hoonah

Hoonah is located on Port Frederick, along Icy Strait on the northeast shore of Chichagof Island, 40 air miles west of Juneau. Hoonah is predominantly a Native community and has been the principal village for the Hoonah Tlingit Clans since the late 1800s. According to the 2000 Census, Hoonah had a 2000 population of 501, with Alaska Natives comprising 61 percent of the total (U.S. Census Bureau 2001). Whitestone Logging Camp, with a population of 116 (U.S. Census Bureau 2001), is adjacent to Hoonah. The community of Game Creek, a religious ministry, is located 2.6 miles southwest of Hoonah.

The village of Hoonah has been occupied since prehistoric times by the Tlingit people. Groups of Huna Tlingit lived all or part of the year at seasonal camps and small winter settlements throughout the Huna territory. Dozens of camps and settlements have been documented through archaeological surveys. The Hoonah Tlingit have very close ties to the Glacier Bay area across Icy Strait.

In 1880, the Northwest Trading Company built a store in Hoonah. The following year, missionaries settled in the town and established the Presbyterian Home Mission church and school. By 1887, about 500 people were wintering in the village. When the post office was established in 1901, the village was officially named Hoonah, which means "village by the cliff" in Tlingit. In 1944, fire burned many homes in Hoonah and destroyed the traditional ceremonial costumes and keepsakes of the villagers. The town has since been rebuilt and has become a center for logging operations on northern Chichagof Island (ADF&G 1994). A sort yard and log transfer facility are located at Long Island. The community has a local Fish and Game Advisory Committee (ADF&G 1994).

Icy Strait Point, an old cannery located approximately 1.5 miles from in Hoonah opened in 2004 as Alaska's first cruise destination built specifically for tourists. Owned by the Hoonah Totem Corporation and operated by Pt. Sophia Development Corporation. A total of 67,620 cruise passengers visited Hoonah in 2004, 77,498 visited in 2005, and 135,519 cruise visitors were projected for 2006 (Cruise Line Agencies of Alaska 2006).

The Icy Straits Lumber Company and D&L Woodworks are both located in Hoonah. According to the 2006 mill survey conducted for the USDA Forest Service, the Icy Straits mill, which had an installed production capacity of 20 MMBF, processed approximately 0.7 MMBF in 2006 and employed 15 people (Juneau Economic Development Council 2007). D&L Woodworks had an installed production capacity of 1.8 MMBF and processed 0.1 MMBF in 2007, supporting approximately 1.5 years of full-time employment (Juneau Economic Development Council 2007). This processing total represented 3 percent and 6 percent of the existing capacity at the Icy Straits and D&L Woodworks facilities, respectively.

The population of Hoonah increased by 65 people or 8 percent between 1990 and 2000 and stayed essentially constant between 2000 and 2005. Total estimated population was 829 in Hoonah in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	748	680	795	860	861	829

Source: USDA Forest Service 1997a; U.S. Census Bureau 2001; Alaska DOL 2007a

Hoonah has a diverse economy with nearly full employment during the summer season. A total of 117 residents hold commercial fishing permits. Fishing, logging, and local government are the main employers. Estimated gross fishing earnings of local residents exceeded $1.5 million in 2000. Fish processing occurs at plants in Hoonah and nearby Excursion Inlet. Sealaska Timber Corporation employs a number of local residents through contracts with Whitestone Logging, Inc. and Southeast Stevedoring. The Huna Totem Corporation owns and operates a sort yard and timber transfer facility. The City of Hoonah and the school district are the major public sector employers (Alaska DCED 2002). Residents are also employed by the recently opened Icy Strait Point development. A total of 67,620 cruise passengers visited Hoonah in 2004, 77,498 visited in 2005, and 135,519 cruise visitors are projected for 2006 (Cruise Line Agencies of Alaska 2006).

The economy of Hoonah has undergone a major transformation in recent years with the completion of Icy Strait Point (Dugan et al. 2006). Icy Strait Point is the largest single employer in Hoonah, with 124 employees, mostly Hoonah residents, working there three to four days a week. Icy Strait Point includes a museum and serves as a base for tours, including forest tours, whale watching, and fishing charters. These tours served an estimated 30,000 people in 2005 (Dugan et al. 2006).

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. Approximately 21 percent of the labor force in Hoonah was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $39,028, compared to a regional median of $44,118 (Alaska DCED 2002).

Employment by Industry	Number	Percent of Total

Total Employment	**317**	**100**

Source: Alaska DCED 2002

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Hoonah is part of the North Chichagof community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record for this EIS. Manufacturing and non-federal government were the major employers in the North Chichagof community group in 1999, accounting for 34 and 30 percent of total employment, respectively. Logging and seafood processing accounted for 24 and 10 percent of total employment, respectively.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Hoonah in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-10. This area contains 583,825 acres of National Forest System land (among other land ownerships). Table 3.23-24 shows how the land within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs presently account for 46 percent of the total acreage within the Hoonah community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 through 3. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 51 percent under Alternative 5 (No Action) to 87 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-24). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 58 percent and 69 percent under Alternatives 4 and 7, respectively, compared to 46 percent under Alternative 5.

Total suitable acres would range from 3 percent under Alternative 1 to 19 percent under Alternative 7, compared to 10 percent of the total community use area under Alternative 5 (No Action).

Economy

Commercial fishing, logging, and subsistence use are important to Hoonah. The Icy Straits sawmill, which is located in Hoonah, employed 15 people in 2006. Hoonah residents are also employed by the recently opened Icy Strait Point development. Commercial fishing is not expected to be significantly affected under any of the alternatives.

The Icy Straits sawmill had approximately 8 MMBF under contract in August 2006. Approximately 30 percent (2.5 MMBF) of this volume could be potentially affected under Alternative 1. None of the other alternatives would affect this volume. These data provide an indication of potential impacts, actual impacts would depend on the volume that is under contract when the decision is implemented and whether potentially affected existing sales were cancelled as part of the decision.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 59 percent of the total edible pounds of subsistence resources harvested by Hoonah households (Kruse and Frazier 1988). Marine resources (fish and marine invertebrates) accounted for 74 percent of per capita subsistence harvest in Hoonah in 1996.

The 1988 TRUCS study found that deer accounted for 23 percent of the total edible pounds of subsistence resources harvested by Hoonah households (Kruse and Frazier 1988). Deer accounted for 14 percent of per capita subsistence harvest by Hoonah residents (ADF&G 2006).

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

Hoonah residents mainly harvest deer on Chichagof Island, which is included in GMU 4. Deer harvest in GMU 4 is considered very high relative to other areas of Southeast Alaska, which is indicative of relatively high deer populations (ADF&G 2005). Over 1997-2004, there has been no significant trend in the number of deer harvested or in the number of hunters (ADF&G 2005). As noted above, the human population of Hoonah increased steadily from 1970 through 2000 and remained relatively constant from 2000 to 2005. Hoonah had an estimated population of 861 in 2005.

Four WAAs account for the majority (74 percent) of deer harvest by Hoonah residents (Table 3.23-25). The Hoonah portion represents from 78 percent to 93 percent of the rural hunter harvest and from 49 percent to 70 percent of the total harvest in these WAAs. About 35 percent of the combined harvest in these WAAs is by non-rural hunters, suggesting that there is a harvest buffer that could be restricted, if necessary, before restrictions are placed on rural harvests.

Table 3.23-25
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Hoonah Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

WAA	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability

3523	92	99	164	81	76	74	74	72	73	73	63
3525	83	107	171	78	71	67	67	62	65	66	58
3524	63	71	90	100	100	86	85	79	83	84	78

*Calculated based on harvest where location is known

Three of the WAAs identified in Table 3.23-26 are in areas with substantial past harvest and deer habitat capabilities are currently estimated to be considerably below 1954 levels. Under each of the alternatives, additional harvest would further reduce habitat capabilities. Reductions would be smallest under Alternatives 1 and 2 and greatest under Alternative 7.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that the 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide sufficient habitat capability for deer hunted by Hoonah residents in the short term. Projected deer harvest in the Hoonah community use area for all rural hunters and all hunters would exceed 10 percent habitat capability, the level that the analysis assumed would provide a reasonably high level of hunter success for their effort, in the short term. Projected harvest for Hoonah residents was estimated to exceed this level in the long term. The Final EIS analysis concluded that at some point a restriction in hunting might be necessary.

In summary, use of most subsistence resources by Hoonah residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives. However, subsistence use of deer may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1. The risks of this occurring are greatest under Alternative 7 because of its general lack of Non-Development LUDs in Hoonah's community use area, and second highest under Alternative 4 because of its lower use of Non-Development LUDs than the other alternatives (Table 3.23-25). Alternatives 1, 2, and 3 would have the lowest risk and Alternatives 5 and 6 would be intermediate. The risk of hunting restrictions would be reduced somewhat, through more intensive management (e.g., thinning) of the existing and future closed-canopy, young-growth forests in this area. Indirect effects associated with increased competition for deer within Hoonah's subsistence use areas could also occur under all alternatives due to displacement of hunters from other communities due to timber harvest activity. Additional road development under the alternatives would improve access but may increase competition with other non-local hunters. The level of road development is already relatively high in these WAAs. Existing open road densities range from 0.4 to 2.1 miles per square mile and existing total road densities range from 0.8 to 2.1 miles per square mile (for all ownerships combined). Long-term (100+ years) road development would vary by alternative and would result in estimated maximum total road densities ranging from 1.1 to 3.1 miles per square mile in these WAAs under Alternative 1, to 1.5 to 3.4 miles per square mile in these WAAs under Alternative 7 (for all ownerships combined).

Hydaburg

Hydaburg is located on the southwest side of Prince of Wales Island, 45 air miles northwest of Ketchikan. According to the 2000 Census, Hydaburg had a 2000 population of 382, with Alaska Natives comprising 85 percent of the total (U.S. Census Bureau 2001).

The Haida Indians migrated to Prince of Wales Island, a predominantly Tlingit area, from Graham Island, Canada. After combining three villages, the present site was chosen initially as the Hydaburg Indian Reservation in 1912. It became a fishing village with the first fish processing plant opening in 1927, and three other canneries operating through the 1930s. Seafood processing was active until 1984 when a fire destroyed the cannery (ADF&G 1994). Hydaburg is connected by road to Craig, Klawock, Hollis, and northern parts of the Island.

In 1936, Hydaburg became the first Alaskan Native village to form an Indian Reorganization Act Council. In 1972, Hydaburg incorporated as a first class city. The community has a local Fish and Game Advisory Committee (ADF&G 1994).

Hydaburg's population increased by 79 percent between 1970 and 1990, but remained fairly constant between 1990 and 2000, and decreased slightly (3 percent) between 2000 and 2005. Total estimated population was 352 in Hydaburg in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	214	298	384	382	369	352

Source: USDA Forest Service 1997a; U.S. Census Bureau 2001; Alaska DOL 2007a

Hydaburg's economy is based primarily on the timber and fishing industries. A total of 39 residents hold commercial fishing permits. The Haida Corporation has a substantial timber holding, a log storage facility, and a sort yard. It suspended logging in 1985 due to a decline in the timber market and leases the storage facility and sort yard to Sealaska Corporation. The city of Hydaburg, Sealaska Corporation, Haida Corporation, and SEARHC are the leading employers. Potential development ideas for the community include a fish processing facility, a U.S. Forest Service Visitor Center, specialty woodworking, and some type of retail center (Alaska DCED 2002).

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. Approximately 31 percent of the labor force in Hydaburg was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $31,625, compared to a regional median of $44,118 (Alaska DCED 2002).

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Hydaburg is part of the Hydaburg community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record for this EIS. Non-federal government and services were the main employers in the Hydaburg community group in 1999, accounting for 48 and 19 percent of total employment, respectively.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Hydaburg in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-11. This area contains 764,430 acres of National Forest System land (among other land ownerships). Table 3.23-26 shows how the land within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs presently account for 44 percent of the total acreage within the Hydaburg community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 through 3. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 44 percent under Alternative 5 (No Action) to 77 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-26). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 54 percent and 59 percent under Alternatives 4 and 7, respectively, compared to 44 percent under Alternative 5.

Total suitable acres would range from 5 percent under Alternative 5 to 19 percent under Alternative 7, compared to 12 percent of the total community use area under Alternative 5 (No Action) and Alternative 6 (Proposed Action).

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

Economy

Subsistence use and commercial fishing are the primary elements of Hydaburg's economy. Commercial fisheries employment is not likely to be affected under any of the alternatives.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 80 percent of the total edible pounds of subsistence resources harvested by Hydaburg households (Kruse and Frazier 1988). Marine resources (fish and marine invertebrates) accounted for the majority (85 percent) of per capita subsistence harvest in Hydaburg in 1997.

The 1988 TRUCS study found that deer accounted for 13 percent of the total edible pounds of subsistence resources harvested by Hydaburg households (Kruse and Frazier 1988). Deer accounted for 9 percent of per capita subsistence harvest by Hydaburg residents in 1997 (ADF&G 2006).

Hydaburg residents primarily harvest deer on south Prince of Wales Island, which is included in GMU 2. Deer harvest and hunter effort in GMU 2 generally increased during 1997-2000 and subsequently declined during 2000-2004; however, no changehas been noted in the average number of hunter-days required to harvest a deer (ADF&G 2005). As noted above, Hydaburg's human population increased steadily from 1970 through 1990 and decreased slightly from 2000 to 2005. Hydaburg had an estimated 2005 population of 861.

Residents of Hydaburg harvest the majority (75 percent) of their deer from two WAAs in central Prince of Wales Island (1107 and 1214) (Table 3.23-27). The Hydaburg portion represents about 47 percent of the total harvest and 53 percent of rural hunter harvest in WAA 1107 and less than 10 percent of total and rural harvest in WAA 1214. Non-rural harvest comprises 10 percent of total harvest in WAA 1107 and 42 percent in WAA 1214. This suggests that there is a limited harvest buffer that could be restricted, if necessary, before restrictions are placed on rural harvests.

Table 3.23-27
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Hydaburg Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability							
WAA	Hydaburg Residents	All Rural Hunters	All Hunters	2005	Alt 1	Alt 2	Alt 3	Alt 4	Alt 5	Alt 6	Alt 7
1107	19	37	41	98	97	97	97	88	90	90	86
1214	3	53	91	79	70	66	65	62	64	64	53

*Calculated based on harvest where location is known

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that the 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide sufficient habitat capability for deer hunted by Hydaburg residents, as well as for all deer hunted within the WAAs of the Hydaburg community use area in the long term.

In summary, use of most subsistence resources by Hydaburg residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives.

However, subsistence use of deer may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1. The risks of this occurring are greatest under Alternative 7 because of its general lack of Non-Development LUDs throughout most of Prince of Wales Island, and second highest under Alternative 4 because of its lower use of Non-Development LUDs than the other alternatives. Alternatives 1, 2, and 3 would have the lowest risk and Alternatives 5 and 6 would be intermediate. The risk of hunting restrictions would be reduced somewhat, through more intensive management (e.g., thinning) of the existing and future closed-canopy, young-growth forests in this area. Indirect effects associated with increased competition for deer within Hydaburg's subsistence use areas could also occur under all alternatives due to displacement of hunters from other communities due to timber harvest activity. Additional road development under the alternatives would improve access but may increase competition with other non-local hunters. The level of road development is already relatively high in these WAAs. Existing open road densities are 0.9 and 1.5 miles per square mile and existing total road densities are 0.9 and 1.6 miles per square mile in WAAs 1107 and 1214, respectively (for all ownerships comined). Long-term (100+ years) road development would vary by alternative and would result in estimated maximum total road densities ranging from 1.5 to 2.3 miles per square mile in these WAAs under Alternative 1, to 1.5 to 2.7 miles per square mile in these WAAs under Alternative 7 (for all ownerships combined).

Hyder

Hyder is a small community located at the head of Portland Canal, a 70-mile-long fjord that forms part of the United States/Canadian border. Hyder is just 2 miles from Stewart, British Columbia, and 75 air miles from Ketchikan. Hyder is one of three Alaskan communities connected by road to Canada. According to the 2000 Census, Hyder had a 2000 population of 97, with no Alaska Native population (U.S. Census Bureau 2001).

Nass River Tsimshians inhabited the area, which they called Skam-a-Kounst, "a safe place," prior to the coming of white prospectors in the late 1890s. The first official exploration and building at the town site occurred in 1896 by the U.S. Army Corps of Engineers. Stewart also became settled at this time, as gold, silver, and other mineral mining operations developed. The two towns grew together with an initial economic base in mining (ADF&G 1994).

The population of Hyder, which slightly more than doubled between 1970 and 1990, remained fairly constant between 1990 and 2005, decreasing by an estimated 6 persons. Total estimated population was 92 in Hyder in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	49	77	99	97	91	92

Source: USDA Forest Service 1997a; U.S. Census Bureau 2001; Alaska DOL 2007a

Hyder's economy is primarily based on tourism and, as such, is seasonal. Four of the five largest employers are tourist related. Four residents hold commercial fishing permits. Many tourists enter Hyder from Canada. Stewart, British Columbia and Hyder are only 2 miles apart and share visitor services. A bottled water business opened in 1998 and employs several local residents (Alaska DCED 2002).

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. Approximately 47 percent of the labor force in Hyder was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $11,719 compared to a regional median of $44,118 (Alaska DCED 2002).

Total Employment	**24**	**100**

Source: Alaska DCED 2002

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Hyder is part of the Hyder community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record for this EIS. The Federal government and services sectors were the main employers in the Hyder community group in 1999, accounting for 69 and 25 percent of total employment, respectively.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Hyder in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-12. This area contains 108,809 acres of National Forest System land (among other land ownerships). Table 3.23-28 shows how the land within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs presently account for 10 percent of the total acreage within the Hyder community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 through 3. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 90 percent under Alternative 5 (No Action) to 100 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-28). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 31 percent under Alternatives 4 and 7 compared to 10 percent under Alternatives 5 and 6.

Total suitable acres would range from 0 under Alternative 1 to 5 percent under Alternatives 4 and 7, compared to 3 percent of the total community use area under Alternative 5 (No Action) and Alternative 6 (Proposed Action).

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

Economy

Hyder is a small former mining town that now relies upon tourism and commercial fishing for the majority of its income. Tourism (especially bear viewing) has become increasingly important to the economy of Hyder. A number of organizations commenting on the Draft EIS pointed out that the area around Hyder is a well-known mining area (as noted above) and stated that several old mines in the area are being evaluated for further development and a number of new projects have been identified and are in various stages of development. These organizations requested that the LUD classification in this area be changed from Semi-remote Recreation to a Moderate Development LUD with a Minerals overlay. A Minerals overlay has been added to this area in the Final Proposed Plan under all of the action alternatives. The Minerals LUD overlay may have the effect of changing potential exploration and development costs from high to moderate in the affected area. This is discussed further in the *Minerals* section of this EIS.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 80 percent of the total edible pounds of subsistence resources harvested by Hyder households (Kruse and Frazier 1988). Marine resources (fish and marine invertebrates) accounted for the majority (85 percent) of per capita subsistence in Hyder in 1987.

The 1988 TRUCS study found that deer accounted for only a fraction of the total edible pounds of subsistence resources harvested by Hyder households (Kruse and Frazier 1988). Deer accounted for a very small amount of per capita subsistence harvest by Hyder residents in 1987.

Data were not provided for Hyder in the ADF&G deer harvest reports for 1996 to 2002. The majority of deer harvest by Hyder residents likely takes place in GMU 1A. Deer harvest in GMU 1A generally declined from 1997 to 2004, with the number of hunters and hunter effort also decreasing over this period (ADF&G 2005). As noted above, the population of Hyder increased from 1970 through 1990 and has remained fairly constant since. Hyder had an estimated population of 91 residents in 2005.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide sufficient habitat capability for deer hunted in Hyder's community use area by Hyder residents, all rural hunters, and all hunters in the short term. In the long term projected harvest for all rural hunters and all hunters in the Hyder community use area would exceed 10 percent habitat capability, the level that the analysis assumed would provide a reasonably high level of hunter success for their effort.

In summary, use of most subsistence resources by Hyder residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives. However, subsistence use of deer may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1. The risks of this occurring are greatest under Alternative 7 and second highest under Alternative 4, because of their lower use of Non-Development LUDs compared with the other alternatives. Alternatives 1, 2, and 3 would have the lowest risk and Alternatives 5 and 6 would be intermediate. It is unlikely that Hyder residents would be affected by increased competition or access in WAA 826, which surrounds their community, because of the limited access to this area. Existing road densities are also relatively low and total road density is not expected to increase to more than 0.6 mile per square mile even under Alternative 7 (for all lands combined).

Juneau and Vicinity

The city and Borough of Juneau surrounds the Gastineau Channel in Southeast Alaska. Juneau lies approximately 900 air miles northwest of Seattle and 600 air miles southeast of Anchorage. The City and Borough is comprised of three communities: Juneau, Auke Bay, and Douglas. According to the 2000 Census, the City and Borough of Juneau had a 2000 population of 30,711, accounting for 42 percent of the population in Southeast Alaska. Alaska Natives comprised almost 11 percent of the total population (U.S. Census Bureau 2001).

Originally, Tlingit Indians made seasonal and permanent villages along the north and south coast near the present site of Juneau. Gold discovered in the Juneau area started the mining town in 1880 and the settlement grew rapidly. Two of the world's largest lode gold mines produced over $180 million in gold before finally closing in 1944. The state capital was moved from Sitka to Juneau in 1906 while Alaska was still a territory. Alaska became the 49th State in 1959. Juneau has developed as a government and regional services center, with added economic contributions from fishing and tourism.

The population of Juneau has grown steadily since 1970, almost doubling between 1970 and 1990 and increasing a further 15 percent between 1990 and 2000. The population in Juneau has continued to growth, increasing by approximately 2 percent (482 residents) between 2000 and 2005. Total estimated population was 30,650 in Juneau in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	13,556	19,528	26,751	30,711	31,193	30,650

Source: USDA Forest Service 1997a; U.S. Census Bureau 2001; Alaska DOL 2007a

The Juneau economy is primarily based on government, tourism, support services for logging, fish processing and mining. The State, city and Borough of Juneau, and federal agencies provide nearly 45% of the employment in the community. Juneau is the State capital and is the home of the State legislators and their staff during the legislative season (January to May). Tourism is a significant part of the economy during the summer months providing an estimated $130 million in income. Juneau is an important cruise ship docking location due to the local attractions: Mendenhall Glacier, Juneau Icefield, Tracy Arm Fjord Glacier, and the new Mount Roberts Tram. Estimated gross fishing earnings of local residents exceeded $10.4 million in 2000. Cold storage facilities in Juneau process over 2 million pounds of seafood annually and DIPAC, a private non-profit organization, operates a salmon hatchery. The Kennecott Green's Creek Mine, the largest silver mine in North America, produces gold, silver, lead and zinc (Alaska DCED 2002). In addition, the Forest Service approved a plan of operations for the Kensington Gold Mine north of Juneau in 2005 and Coeur Alaska, Inc. subsequently began construction activities on the site. Construction and development was, however, halted by legal challenges and the Forest Service now anticipates the submittal of a revised plan of operations in 2008.

Tourism in Juneau is dominated by cruise ships, but a recent study noted that a substantial number of independent unguided travelers also make their way through Juneau in pursuit of hiking, kayaking, boating, hunting, and other outdoor activities (Dugan et al. 2006). The six major cruise lines who dock at Juneau each offer 34 to 37 shore excursions for purchase on the ship or before the cruise begins.

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. Approximately 5 percent of the labor force in Juneau was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $62,034, compared to a regional median of $44,118 (Alaska DCED 2002).

Employment by Industry	Number	Percent of Total

Total Employment	**16,537**	**100**

Source: Alaska DCED 2002

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Juneau is part of the Juneau community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record for this EIS. Non-federal government, services, and retail trade were the main employers in the Juneau community group in 1999, accounting for 37, 21, and 15 percent of total employment, respectively. Recreation-related activities (lodging, restaurants, and recreation services) accounted for 11 percent of total employment.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Juneau in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-13. This area contains 2,013,397 acres of National Forest System land (among other land ownerships). Table 3.23-29 shows how the land within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs presently account for 8 percent of the total acreage within the Juneau community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 through 3. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 73 percent under Alternative 5 (No Action) to 80 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-29). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 10 and 11 percent under alternatives 4 and 7, respectively, compared to 8 percent under Alternative 5.

Total suitable acres would range from no acreage under Alternatives 1 through 3 to 2.4 percent under Alternative 7, compared to 1.6 percent of the total community use area under Alternative 5 (No Action).

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

Economy

As the State capital, government is important to Juneau. Besides changes in government employment, Juneau is most likely to be affected by changes in mining, recreation and tourism, and commercial fishing. None of the alternatives are expected to affect these aspects of the local economy.

Subsistence

Juneau is not classified as a subsistence community; however, many residents use the surrounding Tongass for sport hunting and fishing. Juneau is the largest community in Southeast Alaska and accounted for 44 percent of the region's population in 2005, with an estimated total of 31,193 residents. Given the non-subsistence status of the community and its large size, no attempt is made here to summarize the WAAs that community residents use to hunt deer. The following paragraphs do, however, summarize the findings of the 1997 EIS and provide a general overview of the likely impacts of the current alternatives.

The majority of deer harvest by Juneau residents likely takes place within the community's identified use area (Figure 3.23-13), which is mainly located within GMU 1C. GMU 1C has been characterized from 1997-2004 by substantial annual variation in deer harvest, with no evident long-term trend in harvest levels (ADF&G 2005).

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide sufficient habitat capability for deer hunted by all rural hunters in the long term. Projected deer harvest in the Juneau community use area by all rural hunters and Juneau residents and all hunters was estimated to exceed 10 percent habitat capability; the level that the analysis assumed would provide a reasonably high level of hunter success for their effort in the short term and long term. The Final EIS analysis concluded that at some point a restriction in hunting might be necessary.

In summary, use of most subsistence resources by Juneau residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives. However, subsistence use of deer may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1. The risks of this occurring are greatest under Alternative 7, and second highest under Alternative 4 because of its lower use of Non-Development LUDs than the other alternatives. Alternatives 1, 2, and 3 would have the lowest risk and Alternatives 5 and 6 would be intermediate.

Kake

Kake is located on west Kupreanof Island, along Keku Strait, 38 air miles northwest of Petersburg. According to the 2000 Census, Kake had a 2000 population of 710, with Alaska Natives comprising 67 percent of the total (U.S. Census Bureau 2001).

Tlingit Alaska Natives villages and fishing camps in the Kake area pre-date non-Alaska Native explorations of Southeast Alaska. During the 1800s these villages were consolidated at the present site of Kake. In the years following the American purchase of Alaska from Russia in 1867, there were several confrontations between the *Keex'* Tlingit and the Russian and American military administrations culminating in the destruction of three Kake villages. For many years, the *Keex'* people did not rebuild their villages. Eventually, they concentrated on Kupreanof Island at the present townsite along Keku Strait (ADF&G 1994).

The period of 1880 through 1915 brought a territorial government, missionary activity, economic innovations, and a larger white population into *Keex'* Tlingit territory. By the 1920s, Kake had become self-governing, with a mayor and police chief. In 1949, Kake formed an IRA Council under the Indian Reorganization Act of

1936. In 1952, Kake became incorporated as a first class city. In 1971, the passage of ANCSA resulted in the incorporation of the village and the selection of corporation lands (ADF&G 1994).

The population of Kake, which increased by 56 percent between 1970 and 1990, remained fairly constant between 1990 and 2000, and decreased by an estimated 112 people or 16 percent between 2000 and 2005. Total estimated population was 536 in Kake in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	448	555	700	710	598	536

Source: USDA Forest Service 1997a; U.S. Census Bureau 2001; Alaska DOL 2007a

The Kake economy is primarily based on timber and fishing industries. Sixty-seven residents hold commercial fishing permits. The city, including the school district, and the timber industry are the largest employers. Turn Mountain Timber, a joint venture between Whitestone logging and Kake Tribal Logging, and the log sort yard and transfer facility at Point McCarny employ a number of local residents. Kake Tribal Corporation, which owns a local cold storage plant and Ocean Fresh Seafoods, is the largest individual employer. The Gunnock Creek Hatchery, a non-profit organization, operates a salmon hatchery to assist in sustaining the salmon fishery in the area (Alaska DCED 2002).

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. Approximately 25 percent of the labor force in Kake was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $39,643, compared to a regional median of $44,118 (Alaska DCED 2002).

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Kake is located in the Petersburg Ranger District and part of the Kake community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record for this EIS.

The non-federal government, finance, insurance, and real estate (F.I.R.E), and manufacturing sector were the major employers in the Kake community group in 1999, accounting for 28, 22, and 21 percent of total employment, respectively. Wood products (logging) employment decreased by 57 percent between 1990 and 1999, declining from 123 to 53 jobs. Wood products employment accounted for 21 percent of total employment in the Kake community group in 1999.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Kake in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-14. This area contains 454,186 acres of National Forest System land (among other land ownerships). Table 3.23-30 shows how the land within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Figure 3.23-14
Kake's Community Use Area

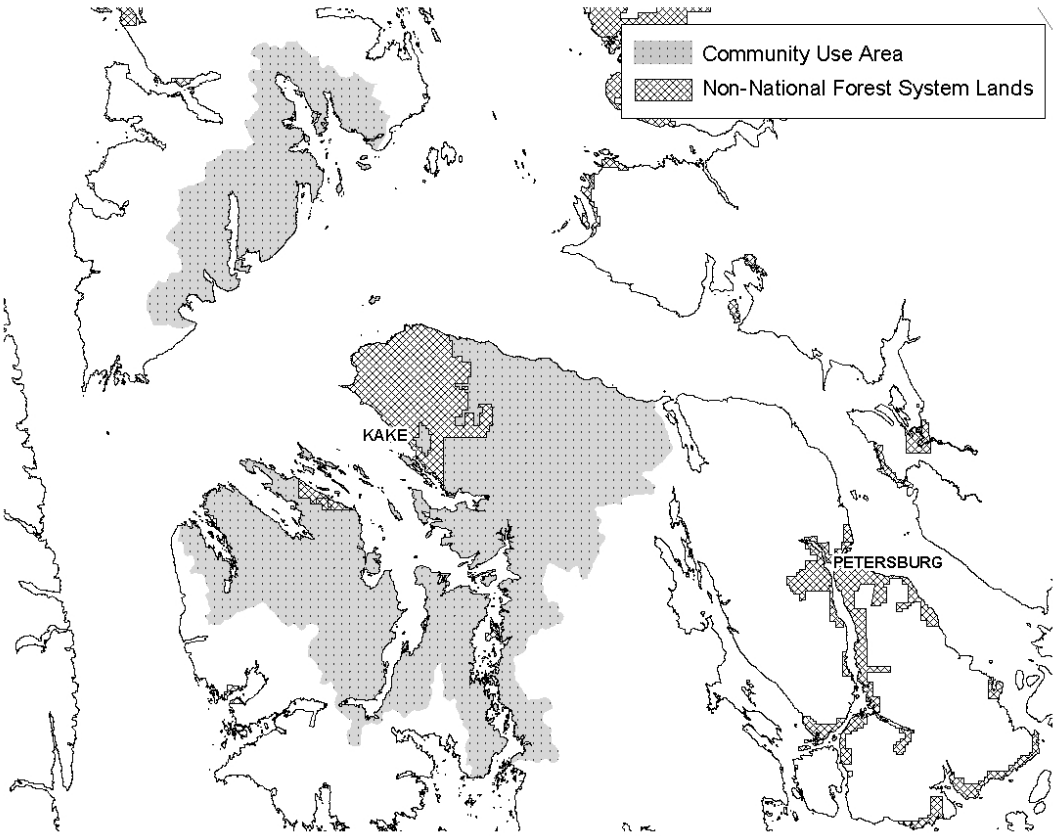

Table 3.23-30
LUD Groups in Kake's Community Use Area by Alternative

Total	**454,187**	**454,185**	**454,210**	**454,188**	**454,186**	**454,185**	**454,186**

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

Development LUDs presently account for 44 percent of the total acreage within the Kake community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 through 3. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 33 percent under Alternative 5 (No Action) to 69 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-30). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 52 percent and 57 percent under Alternatives 4 and 7, respectively, compared to 44 percent under Alternatives 5.

Total suitable acres would range from 4 percent under Alternative 1 to 19 percent under Alternative 7, compared to 16 percent of the total community use area under Alternative 5 (No Action).

Economy

Kake is a traditional native community where commercial fishing, timber harvesting, and subsistence use are important. For subsistence use, west Kupreanof and north Kuiu Islands are some of the most important areas.

Timber harvest has been an important contributor to the Kake economy for approximately 20 years. During that period, both private and National Forest System lands have been harvested. Recently, timber harvest has diminished on both ownerships. Logging employment in the Kake community group declined by 70 jobs or 57 percent between 1990 and 1999, but still comprised 21 percent of total employment in 1999 (Table 3.23-7).

A total of 20.6 MMBF is presently under contract in the Petersburg Ranger District. Approximately 22 percent or 4.6 MMBF of this volume would be affected under Alternative 1, which would maintain all Inventoried Roadless Areas on the Tongass in a natural condition and not permit timber harvest in these areas. None of the other alternatives would affect this volume. These data provide an indication of potential impacts, actual impacts would depend on the volume that is under contract when the decision is implemented and whether potentially affected existing sales were cancelled as part of the decision.

Commercial fishing is not expected to be significantly affected under any of the alternatives.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 52 percent of the total edible pounds of subsistence resources harvested by Kake households (Kruse and Frazier 1988). Marine resources (fish and marine invertebrates) accounted for 60 percent of per capita subsistence harvest in Kake in 1996.

The 1988 TRUCS study found that deer accounted for 24 percent of the total edible pounds of subsistence resources harvested by Kake households (Kruse and Frazier 1988). Deer accounted for 28 percent of per capita subsistence harvest by Kake residents in 1996 (ADF&G 2006).

Kake residents harvest deer on Admiralty Island and Kupreanof Island, which are included in GMU 4 and GMU 3, respectively. Deer harvest in GMU 4 is considered very high relative to other areas of Southeast Alaska, which is indicative of relatively high deer populations. Over 1997-2004, there has been no significant trend in the number of deer harvested or in the number of hunters (ADF&G 2005). Deer harvest in GMU 3 declined between 1998-2002 and increased between 2002-2004. The number of deer hunters declined between 2000-2002 and slightly increased between 2002-2004 (ADF&G 2005). As noted above, Kake's human population increased from 1970 to 1990, stayed relatively constant between 1990 and 2000, and decreased from 2000 to 2005. Kake had an estimated 2005 population of 598.

Five WAAs account for the majority (76 percent) of deer harvest by Kake Residents (Table 3.23-31). The Kake portion ranges from about 19 percent (WAA 3939) to 91 percent (WAA 5131) of the total harvest and from 21 percent to 100 percent of the rural hunter harvest in these WAAs. About 7 percent of the combined harvest in these WAAs is by non-rural hunters, suggesting that there is a small harvest buffer that could be restricted, if necessary, before restrictions are placed on rural harvests.

Table 3.23-31
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Kake Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

WAA	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability							
	Kake Residents	All Rural Hunters	All Hunters	2005	Alt 1	Alt 2	Alt 3	Alt 4	Alt 5	Alt 6	Alt 7
3940	35	75	77	92	92	92	92	92	92	92	92
3939	24	114	125	100	100	100	100	100	100	100	100
5132	18	21	21	73	71	68	67	64	65	67	62
5131	15	15	17	90	86	83	83	80	81	82	79
4041	14	24	29	90	90	90	90	90	90	90	90

*Calculated based on harvest where location is known

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that the 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide sufficient habitat capability for deer hunted in the Kake community use area by Kake residents, all rural hunters, and all hunters in the short term. In the long term, the selected alternative (Alternative 11 in the 1997 Forest Plan EIS) should be able to provide sufficient habitat capability for deer hunted in the Kake community use area by Kake residents and all rural hunters. Projected harvest for all hunters in the Kake community use area would, however, exceed 10 percent habitat capability; the level that the analysis assumed would provide a reasonably high level of hunter success for their effort.

In summary, use of most subsistence resources by Kake residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives. However, subsistence use of deer in some of the WAAs hunted by Kake residents may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1. The risks of this occurring are greatest under Alternative 7 because of its general lack of Non-Development LUDs within the Kake use area, and lower under the other six alternatives. The risk of hunting restrictions would be reduced somewhat, through more intensive management (e.g., thinning) of the existing and future closed-canopy, young-growth forests in this area. Indirect effects associated with increased competition for deer within Kake's subsistence use areas could also occur under all alternatives due to displacement of hunters from other communities due to timber harvest activity. The impacts are estimated to be relatively low based on the limited accessibility of these areas to non-local hunters. Three of the five WAAs of highest importance to Kake hunters (WAAs 3939, 3940, and 4041) occur at the south end of Admiralty Island. They are currently unroaded and there are no plans for future road development in these areas. This is not the case for the other two WAAs of importance to Kake hunters (WAAs 5131 and 5132), which are located surrounding or adjacent to the community of Kake on Kupreanof Island. These WAAs, which currently have total road densities of 0.4 and 2.2 miles per square mile, respectively, are projected to have long-term maximum total road densities ranging from 0.6 and 3.2 miles per square mile under Alternative 1 to 1.0 and 3.3 miles per square mile under Alternative 7, respectively (all ownerships combined).

Kasaan

Kasaan is a small village located on the eastern side of Prince of Wales Island 30 miles northwest of Ketchikan. According to the 2000 Census, Kasaan had a 2000 population of 39, with Alaska Natives comprising 38 percent of the total (U.S. Census Bureau 2001).

Originally Tlingit territory, Kasaan gets its name from the Tlingit word meaning "pretty town." Haidas migrated north from the Queen Charlotte Islands in the early 1700s to the Island and established the village known as "Old Kasaan." Between 1892 and 1900, the Copper Queen mine, camp, sawmill, post office, and store were built on Kasaan Bay, and the Haida people relocated to this new village (Alaska DCED 2006). The Haida village of Kasaan was settled at its present site in 1904 (ADF&G 1994).

Kasaan's population grew by 80 percent between 1970 and 1990. The population declined between 1990 and 2000, decreasing by 15 people or 28 percent. The population has increased since 2000, with an estimated 61 people living in Kasaan in 2005. Total estimated population was 59 in Kasaan in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	30	25	54	39	61	59

Source: USDA Forest Service 1997a; U.S. Census Bureau 2001; Alaska DOL 2007a

Most villagers participate in subsistence for supplemental food sources (Alaska DCED 2002).

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. This data is an extrapolation based on information from a sample of residents. Extrapolation of a small sample may have inaccuracies but should provide a general indication of distribution of employment. Approximately 20 percent of the labor force in Kasaan was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $43,500, compared to a regional median of $44,118 (Alaska DCED 2002).

Source: Alaska DCED 2002

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Kasaan is part of the North Prince of Wales community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record for this EIS. Wood products employment in the North Prince of Wales community group declined by 186 jobs or 69 percent between 1990 and 1999. Wood products employment accounted for 83 jobs or 23 percent of total employment in this community group in 1999.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Kasaan in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-15. This area contains 540,324 acres of National Forest System land (among other land ownerships). Table 3.23-32 shows how the land within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs presently account for about 47 percent of the total acreage within the Kasaan community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 through 3. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 45 percent under Alternative 5 (No Action) to 78 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-32). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 61 percent and 72 percent under Alternatives 4 and 7, respectively, compared to 47 percent under Alternative 5.

Total suitable acres would range from 6 percent under Alternative 1 to 24 percent under Alternative 7, compared to 13 percent of the total community use area under Alternative 5 (No Action) and Alternative 6 (Proposed Action).

Total	**540,324**	**540,324**	**540,324**	**540,325**	**540,325**	**540,324**	**540,324**

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

Economy

Subsistence use and commercial fishing are the primary elements of Kasaan's economy. Commercial fisheries employment is not likely to be affected under any of the alternatives. Much of the timber harvest in the vicinity of Kasaan is on private land owned by the Kasaan Native Corporation. This land would not be affected under any of the alternatives.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 74 percent of the total edible pounds of subsistence resources harvested by Kasaan households (Kruse and Frazier 1988) and 75 percent of per capita harvest in 1998 (ADF&G 2006).

The 1988 TRUCS survey found that deer account for 22 percent of the total edible pounds of subsistence resources harvested by Kasaan households (Kruse and Frazier 1988). Deer accounted for 15 percent of per capita subsistence harvest by Kasaan residents in 1998 (ADF&G 2006).

The majority of deer harvest by Kasaan residents takes place near the community on north Prince of Wales Island, which is included in GMU 2. Deer harvest and hunter effort in GMU 2 generally increased during 1997-2000 and subsequently declined during 2000-2004; however, no change has been noted in the average number of hunter-days required to harvest a deer (ADF&G 2005). As noted above, the population of Kasaan fluctuated from 1970 to 2000. From 2000 to 2005 Kasaan's population increased by 56 percent, with an estimated population of 61 in 2005.

Residents of Kasaan harvest the majority (90 percent) of their deer from WAA 1315 on north Prince of Wales Island (Table 3.23-33). The Kasaan portion makes up 1 percent of the total harvest and 2 percent of the rural hunter harvest in this WAA. About 35 percent of the harvest in this WAA is by non-rural hunters, suggesting that there is a harvest buffer that could be restricted, if necessary, before restrictions are placed on rural harvests.

Table 3.23-33
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Kasaan Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability							
WAA	Kasaan Residents	All Rural Hunters	All Hunters	2005	Alt 1	Alt 2	Alt 3	Alt 4	Alt 5	Alt 6	Alt 7
1315	4	175	270	55	50	49	47	44	47	47	41

*Calculated based on harvest where location is known

WAA 1315 occurs in an area with substantial past harvest and, therefore, deer habitat capabilities are currently estimated to be considerably below 1954 levels (Table 3.23-33). Under each of the alternatives, additional harvest would occur that would reduce habitat capabilities after 100+ years to 41-50 percent of 1954 levels (Table 3.23-33).

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that the 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide sufficient habitat capability for deer hunted in the Kasaan community use area by Kasaan residents in the short term and long term. This alternative was also estimated to provide sufficient habitat for all rural hunters in the short term. Projected deer harvest for all hunters in the Kasaan community use area exceeds the level that is both sustainable and provides a reasonably high level of hunter success for their effort in the short term and long term. Projected deer harvest for all rural hunters also exceeds this level in the long term.

Kasaan is currently competing with other communities in their subsistence use areas and this is likely to continue to do so under all alternatives. Alternatives increasing access by road due to harvest activity may increase competition from other communities on Prince of Wales Island indirectly impacting Kasaan's use. An increase in access may also allow Kasaan households to increase the range of their use.

In summary, use of most subsistence resources by Kasaan residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives. However, subsistence use of deer may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1. The risks of this occurring are greatest under Alternative 7 because of its general emphasis on Development LUDs, and lower under the other six alternatives. The risk of hunting restrictions would be reduced somewhat, through more intensive management (e.g., thinning) of the existing and future closed-canopy, young-growth forests in this area. Indirect effects associated with increased competition for deer within Port Protection's subsistence use areas could also occur under all alternatives due to displacement of hunters from other communities due to timber harvest activity. Additional road development under the alternatives would improve access but may increase competition with other non-local hunters. The level of road development is already relatively high in this WAA. Existing open road densities are 1.5 miles per square mile and existing total road densities are 2.0 miles per square mile, respectively (all ownerships combined). Long-term (100+ years) road development would vary by alternative and would result in estimated maximum total road densities ranging from 2.7 miles per square mile in these WAAs under Alternative 1, to 2.9 miles per square mile in these WAAs under Alternative 7 (for all ownerships combined).

Ketchikan

Ketchikan is located on Revillagigedo Island near the southernmost boundary of Alaska. Ketchikan lies approximately 679 miles north of Seattle and 235 miles south of Juneau. It is the first Alaska port-of-call for northbound ships. Ketchikan Gateway Borough includes Ketchikan, Saxman, Mountain Point, Clover Pass, Ward Cove and Herring Cove, which are located on the Ketchikan road system, and Pennock Island.

According to the 2000 Census, Ketchikan Gateway Borough had a 2000 population of 14,070, with 56 percent of the population living in the city of Ketchikan. Alaska Natives make up 18 percent of the borough population (U.S. Census Bureau 2001). Native populations in 1990 varied from a high of 80 percent in Saxman to a low of less than 8 percent in the Ketchikan suburbs. Alaska Natives accounted for 66 percent of total population in Saxman in 2000. Refer to the section on Saxman for information directly relating to that community.

The Ketchikan area was a summer fishing camp for the Tlingit Alaska Natives. Their name for the area, "kitschk-him," meant "thundering wings of an eagle." Its abundant fish and timber resources eventually attracted non-Natives, with the first cannery opening in Ketchikan in 1886 and four more by 1912. Nearby gold and copper discoveries briefly brought activity to Ketchikan during the late 1890s, but timber and fishing became the chief economic forces at the turn of the century and have remained important. The 1954 construction of a pulp mill in Ward Cove continued a tradition begun by the 1903 opening of Ketchikan Spruce Mills, which operated for more than 70 years. Ketchikan has also remained an important hub for fishing, both for fish processing and as home to those with commercial fishing permits (401 area residents).

The population of Ketchikan increased by 14 percent between 1980 and 1990 and then decreased by 4 percent between 1990 and 2000. The population decreased by a further 3 percent (237 residents) between 2000 and 2005. Total estimated population was 7,662 in Ketchikan in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	6,994	7,198	8,263	7,922	7,685	7,662

Source: USDA Forest Service 1997a; U.S. Census Bureau 2001; Alaska DOL 2007a

Ketchikan is an industrial center and a major port of entry in Southeast Alaska. It has a diverse economy, supported by a large fishing fleet, fish processing facilities, timber and tourism. The estimated gross fishing earnings of local residents neared $10 million in 2000. Four canneries, three cold storage facilities, and a fish processing plant support the fishing industry in summer months. Ketchikan is a cruise ship stop and receives over 650,000 annual visitors. While the timber industry is important to the economy with the home base for several timber companies, the Ketchikan Pulp Corporation's pulp mill closed almost a decade ago, in March 1997.

Ketchikan received approximately 887,000 cruise ship visitors in 2005 and has a well-developed network and system of shore-excursions, with 47 shore excursions advertised by the various cruise lines that dock there. Most nature-based activities that originate in Ketchikan fell into four general categories: flightseeing, marine charters, adventure experiences, and general sightseeing. In all cases, the majority of clients participating in these activities were cruise ship passengers (Dugan et al. 2006).

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. Approximately 8 percent of the labor force in Ketchikan was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $45,802, compared to a regional median of $44,118 (Alaska DCED 2002).

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Ketchikan Gateway Borough is comprised of the Ketchikan and Revillagigideo community groups (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record for this EIS.

Since completion of the 1997 Forest Plan EIS analysis, the Ketchikan pulp mill has closed. Closure of the mill, the community's largest employer, resulted in the loss of 500 direct jobs, many of which were high paying and year round. Employment data compiled by the Alaska DOL indicate that employment in the lumber and wood products sector declined from 11.8 percent of total wage and salary employment in 1996 to 5.7 percent in 1999 (Baker 2001). A study by the Alaska DOL found that 3 years after the mill closure about 45 percent of the laid-off workers were employed in other jobs in the Ketchikan/Prince of Wales area, about 15 percent were employed elsewhere in Alaska, and about 40 percent had left the state altogether (Landry 2001).

Gateway Forest Products opened lumber and veneer facilities on the former site of the KPC Pulp Mill in Ketchikan in 2000. Gateway Forest Products filed for bankruptcy protection in February 2002. This application was dismissed by the U.S. Bankruptcy Court in April 2002. The Ketchikan veneer mill restarted in 2007 using timber imported from British Columbia. More recently, the mill has acquired timber from a logging contractor that purchased timber from several Southeast Alaska timber sales (Brackley and Haynes, in press; Damstedt 2007).

The Pacific Log and Lumber sawmill, one of the larger remaining sawmills in Southeast Alaska is also located in Ketchikan. According to the 2006 mill survey conducted for the USDA Forest Service, this mill, which has an installed production capacity of 39.6 MMBF, processed approximately 4.2 MMBF in 2006 and employed 20 people (Juneau Economic Development Council 2007).

Approximately 21 percent of employment in the Ketchikan community group was in non-federal government. Services and retail trade accounted for 21 and 17 percent of total employment, respectively, with recreation-related activities comprising 10 percent of total employment.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Ketchikan in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-16. This area contains 1,975,122 acres of National Forest System land (among other land ownerships). Table 3.23-34 shows how the land within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs presently account for about 21 percent of the total acreage within the Ketchikan community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 through 3. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 31 percent under Alternative 5 (No Action) to 48 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-34). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 32 percent and 33 percent under Alternatives 4 and 7, respectively, compared to 21 percent under Alternative 5.

Total	**1,975,122**	**1,975,122**	**1,975,122**	**1,975,123**	**1,975,123**	**1,975,122**	**1,975,129**

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

Total suitable acres would range from 2 percent under Alternative 1 to 10 percent under Alternative 7, compared to 6 percent of the total community use area under Alternative 5 (No Action) and Alternative 6 (Proposed Action).

Economy

Ketchikan would be primarily influenced by changes in timber processing, recreation and tourism use, commercial fishing, and recreation opportunities, as well as potential restrictions on transportation and utility projects.

Pacific Log and Lumber had approximately 43 MMBF under contract in August 2006. In addition, 24.5 MMBF is presently under contract with Alcan Forest Products, who are located in Ketchikan, but do not operate a facility there. Approximately 75 percent (32.1 MMBF) of the volume under contract with Pacific Log and Lumber could potentially be affected under Alternative 1, which would maintain all Inventoried Roadless Areas on the Tongass in a natural condition and not permit timber harvest in these areas. Alternative 1 would also affect 62 percent (15.2 MMBF) of volume under contract with Alcan Forest Products. None of the other alternatives would affect this volume. These data provide an indication of potential impacts, actual impacts would depend on the volume that is under contract when the decision is implemented and whether potentially affected existing sales were cancelled as part of the decision.

Recreation and tourism have become increasingly important to the economy of Ketchikan, with more than 650,000 cruise ship passengers visiting Ketchikan annually. Ketchikan is also the stopover point for visitors traveling to Misty Fiords and Prince of Wales Island.

Commercial fisheries employment is not likely to be affected under any of the alternatives.

Subsistence

Ketchikan is not classified as a subsistence community; however, many residents use the surrounding Tongass for hunting and fishing. Ketchikan Gateway Borough is the second largest community in Southeast Alaska and accounted for 19 percent of the region's population in 2005, with an estimated total of 13,125 residents. Given the non-subsistence status of the community and its large size, no attempt is made here to summarize the WAAs that community residents use to hunt deer. The following paragraphs do, however, summarize the findings of the 1997 EIS and provide a general overview of the likely impacts of the current alternatives.

The majority of deer harvest by Ketchikan residents likely takes place within the community's identified use area (Figure 3.23-16), which is mainly located within GMU 1A and GMU 2. Deer harvest in GMU 1A generally declined from 1997 to 2004, with the number of hunters and hunter effort also decreasing over this period (ADF&G 2005). Deer harvest in GMU 2 generally increased between 1997 and 2000 and subsequently declined between 2001 and 2004. The average number of days required to harvest a deer, however, remained constant across the entire period (ADF&G 2005).

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that the 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide sufficient habitat capability for deer hunted by all hunters in the short term. However, projected deer harvest in the long term by rural hunters and Ketchikan residents and all hunters exceeds the level that is both sustainable and provides a reasonably high level of hunter success for their effort. If a restriction were necessary, sport hunting by Ketchikan residents would be restricted before subsistence hunting by rural hunters is restricted.

In summary, use of most subsistence resources by Ketchikan residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives. However, subsistence use of deer may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1. The risks of this occurring are greatest under Alternative 7, and second highest under Alternative 4 because of its lower use of Non-Development LUDs than the other alternatives. Alternatives 1, 2, and 3 would have the lowest risk and Alternatives 5 and 6 would be intermediate.

Klawock

Klawock is located on the west coast of Prince of Wales Island, across from Klawock Island, approximately 56 air miles from Ketchikan. It is connected by road to Craig and to other communities on the Prince of Wales Island road system. According to the 2000 Census, Klawock had a 2000 population of 854, with Alaska Natives comprising 51 percent of the total (U.S. Census Bureau 2001).

The mouth of the Klawock River, where the village of Klawock is now located, has been the site of Tlingit occupation for at least the past 600 years. According to oral history, some members of the Kuiu *kwaan* of Kuiu Island moved to Klawock as well (ADF&G 1994). Klawock is now the center of the Tlingit population on west Prince of Wales Island.

The history of Klawock is closely tied to the fishing industry. A trading post and salmon saltery were established in 1868, and the first cannery in Alaska was built here by a San Francisco firm in 1878. A hatchery for red salmon operated at Klawock Lake between 1897 and 1917 (Alaska DCED 2006). In 1929, Klawock incorporated as a first class city. The community has a local Fish and Game Advisory Committee (ADF&G 1994).

The community has been historically dependent on fishing and cannery operations. The timber industry increased in importance in recent years with a relatively large number of residents employed in logging and ship loading in the Klawock and Craig area (Alaska DCED, 2002). Viking Lumber, one of the larger sawmills presently operating in the region, is located between Klawock and Craig. According to the 2006 mill survey conducted for the USDA Forest Service, this mill, which has an installed production capacity of 80 MMBF, processed approximately 19 MMBF in 2006 and employed 42 people (Juneau Economic Development Council 2007).

A total of 47 residents hold commercial fishing permits.

Retail trade and services have become increasingly important to the economy of Klawock. Many residents of communities on northern Prince Wales, as well as recreationists and tourists shop at the shopping center located in Klawock. Klawock has a new airport that has the capacity to accommodate large jet aircraft. The new airport is currently not in commercial operation.

Klawock's population, which more than tripled between 1970 and 1990, increased by 132 people or 18 percent between 1990 and 2000. The population decreased by 74 people or 9 percent between 2000 and 2005. Total estimated population was 776 in Klawock in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	213	318	722	854	780	776

Source: USDA Forest Service 1997a; U.S. Census Bureau 2001.; Alaska DOL 2007a

Historically, the Klawock economy has been dependent on fishing and cannery operations. The cannery operations were closed in the late 1980's and the timber industry has become increasingly important. Sealaska's logging operation, through a contract with Shaan-Seet, Inc., is the largest employer. The City and school district are also significant employers. The state operates a salmon hatchery on Klawock Lake to maintain the local salmon fisheries (Alaska DCED 2002).

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. Approximately 16 percent of the labor force in Klawock was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $35,000, compared to a regional median of $44,118 (Alaska DCED 2002).

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Klawock is part of the Central Prince of Wales community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record for this EIS.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Klawock in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-17. This area contains 767,934 acres of National Forest System land (among other land ownerships). Table 3.23-35 shows how the land within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs presently account for about 55 percent of the total acreage within the Klawock community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain largely the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 through 3. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 39 percent under Alternative 5 (No Action) to 63 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-35). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 64 percent and 72 percent under Alternatives 4 and 7, respectively, compared to 55 percent under Alternative 5.

Total suitable acres would range from 15 percent under Alternative 1 to 28 percent under Alternative 7, compared to 20 percent of the total community use area under Alternative 5 (No Action).

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

Economy

Klawock is a traditional native community. Timber employment, subsistence use, and retail services are most likely to be affected in this community. Viking Lumber one of the larger remaining sawmills in the region is located between Craig and Klawock.

Viking Lumber had 27 MMBF under contract in August 2006. Approximately 17 percent (4.6 MMBF) of this volume could be potentially affected under Alternative 1, which would maintain all Inventoried Roadless Areas on the Tongass in a natural condition and not permit timber harvest in these areas. None of the other alternatives would affect this volume. These data provide an indication of potential impacts, actual impacts would depend on the volume that is under contract when the decision is implemented and whether potentially affected existing sales were cancelled as part of the decision.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 75 percent of the total edible pounds of subsistence resources harvested by Klawock households (Kruse and Frazier 1988). Marine resources (fish and marine invertebrates) accounted for 69 percent of per capita subsistence harvest in Klawock in 1997. The 1988 TRUCS study found that deer accounted for 19 percent of the total edible pounds of subsistence resources harvested by Klawock households (Kruse and Frazier 1988). Deer accounted for 15 percent of per capita subsistence harvest by Klawock residents in 1997 (ADF&G 2006).

Klawock residents mainly harvest deer on north Prince of Wales Island, which is included in GMU 2. Deer harvest and hunter effort in GMU 2 generally increased during 1997-2000 and subsequently declined during 2000-2004; however, no change has been noted in the average number of hunter-days required to harvest a deer (ADF&G 2005). As noted above, the human population of Klawock increased steadily from 1970 to 2000, but decreased by an estimated 9 percent between 2000 and 2005. Klawock had an estimated population of 78 in 2005.

Residents of Klawock harvest the majority (75 percent) of their deer from six WAAs in north Prince of Wales Island (Table 3.23-36). The Klawock portion represents from about 4 percent (WAA 1315) to 31 percent (WAA 1318) of the total harvest and about 6 percent to 37 percent of the rural hunter harvest in these WAAs. About 33 percent of the combined harvest in these WAAs is by non-rural hunters, suggesting that there is a limited harvest buffer that could be restricted, if necessary, before restrictions are placed on rural harvests.

Most of the WAAs identified in Table 3.23-36 occur in areas with substantial past harvest and, therefore, deer habitat capabilities are currently estimated to be below 1954 levels. Under each of the alternatives, additional harvest would occur that would reduce habitat capabilities after 100+ years to 64-85 percent of 1954 levels in WAA 1318 and 41-50 percent in WAA 1315.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that the 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide sufficient habitat capability for deer hunted by Klawock residents in the short term and long term. Projected deer harvest for all rural and for all hunters was estimated to exceed the level that the analysis assumed would provide a reasonably high level of hunter success for their effort in both the short term and long term. At some point a restriction in hunting may be necessary.

Table 3.23-36
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Klawock Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

WAA	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability

1214	10	53	91	79	70	66	65	62	64	64	53

*Calculated based on harvest where location is known

In summary, use of most subsistence resources by Klawock residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives. However, subsistence use of deer may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1. The risks of this occurring are greatest under Alternative 7 because of its low level of Non-Development LUDs throughout most of Prince of Wales Island, and second highest under Alternative 4 because of its lower use of Non-Development LUDs than the other alternatives. Alternatives 1, 2, and 3 would have the lowest risk and Alternatives 5 and 6 would be intermediate. The risk of hunting restrictions would be reduced somewhat, through more intensive management (e.g., thinning) of the existing and future closed-canopy, young-growth forests in this area. Indirect effects associated with increased competition for deer within the Klawock subsistence use areas could also occur under all alternatives due to displacement of hunters from other communities due to timber harvest activity. Additional road development under the alternatives would improve access but may increase competition with other non-local hunters. The level of road development is already relatively high in these WAAs. For example, for the three WAAs with the highest deer harvest by Klawock residents, existing open road densities range from 0.9 to 1.9 miles per square mile and existing total road densities range from 1.5 to 1.9 miles per square mile (all ownerships combined). Long-term (100+ years) road development in these three WAAs would vary by alternative and would result in estimated maximum total road densities ranging from 1.7 to 2.8 miles per square mile under Alternative 1, to 2.0 to 3.0 miles per square mile under Alternative 7 (for all ownerships combined).

Metlakatla

Metlakatla is located on Annette Island, 15 miles south of Ketchikan. According to the 2000 Census, Metlakatla had a 2000 population of 1,375, with Alaska Natives comprising 82 percent of the total (U.S. Census Bureau 2001).

Metlakatla, which is believed to have been occupied at one time by Tlingit Indians, was settled in 1887 by Church of England minister William Duncan and about 830 Tsimshian followers from northern British Columbia. In 1891, an Act of Congress declared Annette Island an Indian Reservation (the Annette Island Reserve), the only one in Alaska. This action set aside the reservation for the exclusive use and occupancy by “Metlakatla Indians and such other Natives of Alaska who might join them” (ADF&G 1994).

Metlakatla is a traditional Tsimshian community with a subsistence lifestyle. The community was not part of ANCSA. The 86,000-acre Island reservation and surrounding 3,000 feet of coastal waters are not subject to State jurisdiction. The Annette Island Reserve regulates commercial fishing in these waters, and operates its own tribal court system (Alaska DCED 2006). The community participates in regional fish and game management issues (ADF&G 1994).

Non-federal government was the largest employer in the Metlakatla community group in 1999, accounting for 322 jobs or 68 percent of total employment. Wood products employment, which decreased by 60 percent (56 jobs) between 1990 and 1999, accounted for 40 jobs or 9 percent of total employment in 1999. These jobs were all in the sawmill sector. The two sawmills located in Metlakatla, Annette Island Sawmill and Metlakatla Forest Products, were both idle in 2005 and are not expected to reopen. A total of 49 residents hold commercial fishing permits.

The population of Metlakatla, which increased by a third between the 1980 and 1990 census, saw a 2 percent decline between 1990 and 2000. The population declined by an estimated 33 people—a further 2 percent—between 2000 and 2005. Total estimated population was 1,377 in Metlakatla in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	1,050	1,056	1,407	1,375	1,342	1,377

Source: USDA Forest Service 1997a; U.S. Census Bureau 2001; Alaska DOL 2007a

Metlakatla is a federal Indian reservation with no local taxes. The economy is based primarily on the fishing and wood products industry. Metlakatla Indian Community, the largest employer, operates a salmon hatchery on Tamgas Creek, the tribal court, and all local services. Annette Island Packing Co. is a cold storage facility in Metlakatla owned by the community (Alaska DCED 2002).

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. Approximately 21 percent of the labor force in Metlakatla was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $43,516, compared to a regional median of $44,118 (Alaska DCED 2002).

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Metlakatla is part of the Metlakatla community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record for this EIS. Non-federal government and retail trade were the main employers in the Metlakatla community group in 1999, accounting for 68 and 10 percent of total employment, respectively.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Metlakatla in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-18. This area contains 1,975,123 acres of National Forest System land (among other land ownerships). Table 3.23-37 shows how the land within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Figure 3.23-18
Metlakatla's Community Use Area

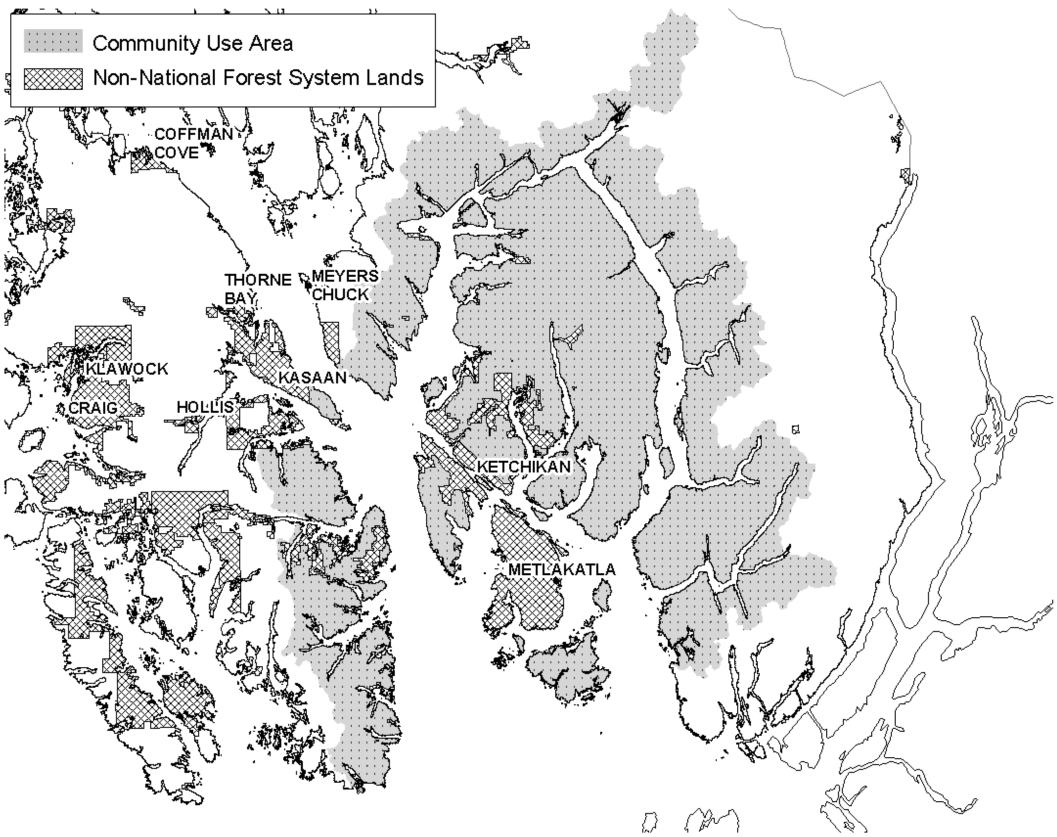

Table 3.23-37
LUD Groups in Metlakatla's Community Use Area by Alternative

	Alternative

Total	**1,975,122**	**1,975,122**	**1,975,122**	**1,975,123**	**1,975,123**	**1,975,122**	**1,975,129**

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

Development LUDs presently account for about 21 percent of the total acreage within the Metlakatla community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 and 2. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 31 percent under Alternative 5 (No Action) to 48 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-37). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 32 percent and 33 percent under Alternatives 4 and 7, respectively, compared to 21 percent under Alternative 5.

Total suitable acres would range from 2 percent under Alternative 1 to 10 percent under Alternative 7, compared to 6 percent of the total community use area under Alternative 5 (No Action) and Alternative 6 (Proposed Action).

Economy

Metlakatla could be affected primarily by changes in commercial fishing, timber processing, and subsistence opportunities.

Commercial fisheries employment is not likely to be affected under any of the alternatives. As noted above, the two sawmills in Metlakatla are presently idle and not expected to re-open. Alternatives 1 and 2 would provide sufficient volume to support the existing Southeast Alaska sawmills operating at their current production levels. The sawmills in Metlakatla would be unlikely to re-open under these alternatives.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 75 percent of the total edible pounds of subsistence resources harvested by Metlakatla households (Kruse and Frazier 1988). Marine resources (fish and marine invertebrates) accounted for 75 percent of per capita subsistence harvest in Metlakatla in 1987.

The 1988 TRUCS study found that deer account for 15 percent of the total edible pounds of subsistence resources harvested by Metlakatla households (Kruse and Frazier 1988). Deer accounted for 15 percent of per capita subsistence harvest by Metlakatla residents in 1987 (ADF&G 2006).

The majority of deer harvest by Metlakatla residents occurs in the vicinity of the community in GMU 1A and on north Prince of Wales Island in GMU 2. Deer harvest in GMU 1A generally declined from 1997 to 2004, with the number of hunters and hunter effort also decreasing over this period (ADF&G 2005). Deer harvest in GMU 2 generally increased between 1997 and 2000 and subsequently declined between 2001 and 2004. The average number of days required to harvest a deer, however, remained constant across the entire period (ADF&G 2005). As noted above, the human population of Metlakatla increased from 1970 to 1990, declined from 1990 to 2000, and declined a further estimated 2 percent from 2000 to 2005. Metlakatla had an estimated population of 1,342 in 2005.

The majority (70 percent) of deer harvest by Metlakatla residents takes place in three WAAs located in the vicinity of the community (WAAs 101, 202, and 405) (Table 3.23-38). Metlakatla residents account for 100 percent of rural harvest in these WAAs and from 33 percent to 90 percent of total harvest. The other WAA identified as important to Metlakatla residents in Table 3.23-38, is located on north Prince of Wales Island. Metlakatal residents account for just 2 percent of rural harvest in this area. About 60 percent of the combined harvest in these WAAs is by non-rural hunters, suggesting that there is a harvest buffer that could be restricted, if necessary, before restrictions are placed on rural harvests.

Table 3.23-38
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Metlakatla Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability							
WAA	Metlakatla Residents	All Rural Hunters	All Hunters	2005	Alt 1	Alt 2	Alt 3	Alt 4	Alt 5	Alt 6	Alt 7

202	8	8	12	0	0	0	0	0	0	0	0
405	3	3	31	83	80	74	73	73	74	73	71
1529	3	122	226	73	63	61	60	56	59	59	50

*Calculated based on harvest where location is known

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that the 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide sufficient habitat capability for deer hunted in the Metlakatla community use area by Metlakatla residents, all rural hunters, and all hunters in both the long term and short term.

In summary, use of most subsistence resources by Metlakatla residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives. However, subsistence use of deer may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1. The risks of this occurring are greatest under Alternative 7 because of its overall emphasis on Development LUDs, and lower under the other six alternatives. The risk of hunting restrictions would be reduced somewhat, through more intensive management (e.g., thinning) of the existing and future closed-canopy, young-growth forests in this area. The two WAAs of highest importance to Metlakatla hunters have existing open and total road densities ranging from less than 0.1 to 0.8 mile per square mile (for all ownerships combined). Long-term (100+ years) road development would vary by alternative and would result in estimated maximum total road densities ranging from 0.2 to 2.3 miles per square mile in these WAAs under

Alternative 1, to 0.5 to 2.3 miles per square mile in these WAAs under Alternative 7 (for all ownerships combined); however, the contribution of Tongass lands to these projected road densities is relatively small.

Meyers Chuck

Meyers Chuck is a small fishing village on the northwest tip of Cleveland Peninsula, 40 miles northwest of Ketchikan. According to the 2000 Census, Meyers Chuck had a 2000 population of 21, none of whom were Alaska Native (U.S. Census Bureau 2001).

Beginning as a protected anchorage for fishing vessels, Meyers Chuck grew with the building of a cannery in Union Bay in 1916. Postal service began in 1922. Fishing and fish processing, and support services sustained the community until the mid-1900s. Fishing and fish processing are still the basic sources of income in the community.

Meyers Chuck's population was the same in 1990 as it was in 1970, but declined by 16 residents, or 43 percent, between 1990 and 2000. The population declined by a further 6 people or 29 percent between 2000 and 2005. Total estimated population was 11 in Meyers Chuck in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	37	50	37	21	15	11

Source: USDA Forest Service, 1997a; U.S. Census Bureau, 2001; Alaska DOL, 2007a

The Meyers Chuck economy is primarily based on fishing with five residents (25 percent of the population) holding commercial fishing licensees. Due to the relatively few cash opportunities, many residents depend on subsistence activities (Alaska DCED, 2002).

Employment by industry data for Meyers Chuck is not included because it was based on a very small sample size and may not be a good indicator of the economy as a whole. The 2000 U.S. Census identified 3 people as employed in a potential workforce of 13 residents. While no adults in Meyers Chuck were identified as unemployed and seeking work in 2000, 77 percent of the population was identified as unemployed and not seeking work. Median household income was $64,375 compared to a regional median of $44,118 (Alaska DCED, 2002).

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Meyers Chuck is part of the Cleveland Peninsula community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Meyers Chuck in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-19. This area contains 380,308 acres of National Forest System land (among other land ownerships). Table 3.23-39 shows how the land within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs presently account for 30 percent of the total acreage within the Meyers Chuck community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 through 3. The largest increase would

Figure 3.23-19

	Alternative						
	1	**2**	**3**	**4**	**5**	**6**	**7**
	Suitable National Forest System Acres for Timber Management						
Suitable Acres	0	2,222	11,711	56,183	31,849	31,259	78,597
LUD Groups	**Acres of National Forest System Land per LUD Group**						
Wilderness/National Monument	48,596	48,596	48,596	48,596	48,596	48,596	48,596
Mostly Natural	329,712	324,174	281,769	134,504	214,661	212,167	89,166
Moderate Development	0	2,191	19,138	69,814	33,310	32,295	92,573
Intensive Development	0	3,348	28,805	125,413	81,742	85,251	147,974
Total	**378,308**	**378,308**	**378,308**	**378,327**	**378,308**	**378,308**	**378,308**

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

occur under Alternatives 1, with the acreage allocated to Mostly Natural LUDs increasing from 56 percent under Alternative 5 (No Action) to 87 percent, with a commensurate reduction in development LUDs (Table 3.23-39). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 52 percent and 64 percent under Alternatives 4 and 7 compared to 30 percent under Alternative 5.

Total suitable acres would range from no acreage under Alternative 1 to 21 percent under Alternative 7, compared to 8 percent of the total community use area under Alternative 5 (No Action) and Alternative 6 (Proposed Action).

Economy

Meyers Chuck is primarily a fishing community and would be primarily influenced by changes in fishing. Commercial fishing is not likely to be affected under any of the alternatives.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 80 percent of the total edible pounds of subsistence resources harvested by Meyers Chuck households (Kruse and Frazier, 1988). Marine resources (fish and marine invertebrates) accounted for the majority (83 percent) of per capita subsistence harvest in Meyers Chuck in 1987.

The 1988 TRUCS study found that deer account for 5 percent of the total edible pounds of subsistence resources harvested by Meyers Chuck households (Kruse and Frazier, 1988). Deer accounted for 5 percent of per capita subsistence harvest by Meyers Chuck residents in 1987 (ADF&G 2006).

The WAAs used by Meyers Chuck residents for hunting deer lie within GMUs 1A, 2, and 4. Meyers Chuck had an estimated population of 15 in 2005 and this is reflected in the small total number of deer harvested by community residents (Table 3.23-40). Four WAAs accounted for more than 75 percent of the annual average harvest by Meyers Chuck residents from 1996 to 2002. The WAA located in GMU 4 (3308) is located outside the Meyers Chuck community use area and was only hunted in one year. This WAA is not considered further in this analysis.

Deer harvest in GMU 1A generally declined from 1997 to 2004, with the number of hunters and hunter effort also decreasing over this period (ADF&G 2005). Deer harvest in GMU 2 generally increased between 1997 and 2000 and subsequently declined between 2001 and 2004. The average number of days required to harvest a deer, however, remained constant across the entire period (ADF&G 2005).

Meyers Chuck residents take almost half (49 percent) of their deer from three WAAs (1003, 614, and 1319). These WAAs would each be affected under the alternatives, with the greatest effects occurring under Alternatives 4 and 7 (Table 3.23-40).

In summary, use of most subsistence resources (fish and marine invertebrates) by Meyers Chuck residents is not expected to be affected under any of the alternatives. Subsistence deer harvest patterns would be most likely to be affected under Alternative 7, which allocates the largest share of WAAs used by Meyers Chuck residents to development LUDs.

Table 3.23-40
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Meyers Chuck Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability

*Calculated based on harvest where location is known.

Naukati Bay

Naukati Bay is a town, approximately 6.5 square miles in size, located on the northwest coast of Prince of Wales Island. According to the 2000 Census, Naukati Bay had a 2000 population of 135, with Alaska Natives comprising 10 percent of the total (U.S. Census Bureau 2001).

The U.S. Coast and Geodetic Survey named the area “Naukatee Nay” in 1904 after the local Native name. Naukati Bay was first developed as a logging camp, but in 1991 an area approximately a mile from the camp was opened by the State Department of Natural Resources as a land disposal site for homesteaders (Alaska DCED 2006).

The population of Naukati Bay increased by 42 people or 45 percent between 1990 and 2000. The population declined by 29 people or 21 percent between 2000 and 2005. Total estimated population was 129 in Naukati Bay in 2006 (Alaska DOL 2007a).

Year	1990	2000	2005	2006
Population	93	135	106	129

Source: USDA Forest Service, 1997a; U.S. Census Bureau 2001; Alaska DOL, 2007a

The Naukati Bay economy is heavily dependent on the timber industry and employment is primarily seasonal. The Naukati Logging camp provides log transfer services for several smaller camps on Prince of Wales Island (Alaska DCED 2002).

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. Approximately 29 percent of the labor force in Naukati Bay was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $27,500, compared to a regional median of $44,118 (Alaska DCED 2002).

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Naukati Bay is located in the Thorne Bay Ranger District and is part of the North Prince of Wales community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record. Wood products employment in the North Prince of Wales community group declined by 186 jobs or 69 percent between 1990 and 1999. Wood products employment accounted for 83 jobs or 23 percent of total employment in this community group in 1999.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Naukati Bay in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-20. This area contains 1,109,349 acres of National Forest System land (among other land ownerships). Table 3.23-41 shows how the lands within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs presently account for 48 percent of the total acreage within the Naukati Bay community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 through 3. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 45 percent under Alternative 5 (No Action) to 63 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-41). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 55 percent and 69 percent under Alternatives 4 and 7, respectively, compared to 48 percent under Alternative 5.

Total suitable acres would range from 15 percent under Alternative 1 to 28 percent under Alternative 7, compared to 19 percent of the total community use area under Alternative 5 (No Action).

Economy

Naukati Bay is primarily a logging community and as such will be directly affected by the amount of logging opportunities on north Prince of Wales Island. Approximately 6.5 MMBF was under contract in the Thorne Bay Ranger District in August 2006. This volume would not be affected under any of the alternatives. These data provide an indication of potential impacts, actual impacts would depend on the volume that is under contract when the decision is implemented and whether potentially affected existing sales were cancelled as part of the decision.

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

Subsistence

Naukati Bay was not surveyed by the Tongass Resource Use Cooperative Survey, and there are no baseline subsistence data for this community. No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. Marine resources (fish and marine invertebrates) accounted for 73 percent of per capita subsistence harvest in Naukati Bay in 1987.

Deer accounted for 19 percent of per capita subsistence harvest by Naukati Bay residents in 1988 (ADF&G 2006).

Naukati Bay residents harvest deer almost entirely on Prince of Wales Island, which is included in GMU 2. Deer harvest and hunter effort in GMU 2 generally increased during 1997-2000 and subsequently declined during 2000 to 2004; however, no change has been noted in the average number of hunter-days required to harvest a deer (ADF&G 2005). As noted above, Naukati Bay's human population decreased by an estimated 21 percent between 2000 and 2005.

Residents of Naukati Bay harvest the majority (78 percent) of their deer from three WAAs on north Prince of Wales Island (1422, 1527, and 1529). As shown in Table 3.23-42, the Naukati Bay portion ranges from 4 percent to 28 percent of the total harvest and from 7 percent to 46 percent of the rural hunter harvest in these WAAs. About 37 percent of the combined harvest in these WAAs is by non-rural hunters, suggesting that there is a harvest buffer that could be restricted, if necessary, before restrictions are placed on rural harvests.

Table 3.23-42
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Naukati Bay Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability							
WAA	Naukati Bay Residents	All Rural Hunters	All Hunters	2005	Alt 1	Alt 2	Alt 3	Alt 4	Alt 5	Alt 6	Alt 7
1422	53	209	300	60	50	48	47	46	47	47	43
1527	14	31	50	73	65	61	60	60	59	59	55
1529	8	122	226	73	63	61	60	56	59	59	50

*Calculated based on harvest where location is known.

WAAs 1422, 1527, and 1529 occur in an area with substantial past harvest and, therefore, deer habitat capabilities are currently estimated to be considerably below 1954 levels (Table 3.23-42). Under each of the alternatives, additional harvest would occur that would reduce habitat capabilities after 100+ years to 43-50 percent of 1954 levels in WAA 1422, 55-65 percent in WAA 1527, and 50-63 percent in WAA 1529.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that the 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide sufficient habitat capability for deer hunted in the Naukati Bay community use area by Naukati residents, all rural hunters, and all hunters in the short term. Projected deer harvest for all rural hunters and all hunters would exceed 10 percent habitat capability, the level that the analysis assumed would provide a reasonably high level of hunter success for their effort in the long term. The Final EIS analysis concluded that at some point a restriction in hunting might be necessary.

In summary, use of most subsistence resources by Naukati Bay residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives. However, subsistence use of deer may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1. The risks of this occurring are greatest under Alternative 7 because of its overall emphasis on Development LUDs within the Naukati Bay use area, and lower under the other six alternatives. The risk of hunting restrictions would be reduced somewhat, through more intensive management (e.g., thinning) of the existing and future closed-canopy, young-growth forests in this area. Indirect effects associated with increased competition for deer within Naukati Bay's subsistence use areas could also occur under all alternatives due to displacement of hunters from other communities due to timber harvest activity. Additional road development under the alternatives would improve access but may increase competition with other non-local hunters. The level of road development is already relatively high in these WAAs. Existing open road densities are 1.0. 0.9, and 0.9 mile per square mile and existing total road densities are 1.9, 1.5, and 1.5 miles per square mile in WAAs 1422, 1527, and 1529, respectively). Long-term (100+ years) road development would vary by alternative and would result in estimated maximum total road densities ranging from 1.7 to 2.1 mile per square mile in these WAAs under Alternative 1, to 1.9 to 2.5 miles per square mile in these WAAs under Alternative 7 (for all ownerships combined).

Pelican

Pelican is a fishing village along Lisianski Inlet on the northwest corner of Chichagof Island, located approximately 70 air miles north of Sitka and 70 air miles west of Juneau. Part of the community is built on pilings over tideland. A boardwalk serves as the town's main thoroughfare due to lack of flat land for roads. According to the 2000 Census, Pelican had a 2000 population of 199, with Alaska Natives comprising 21 percent of the total (U.S. Census Bureau 2001).

Prior to its settlement in 1938, the Pelican area was used as a safe harbor by fishermen and as a hunting, fishing, trapping, and gathering site by Hoonah Tlingit groups, who claimed lands on either side of Cross Sound (ADF&G 1994).

Pelican was incorporated as a second class city in 1943. Pelican employs a full-time city manager and is governed by a mayor and city council. The community has a local Fish and Game Advisory Committee. The Native community, largely Tlingit, is represented by a local Tlingit and Haida Community Council. No Native land allotments or withdrawals occur in the immediate vicinity of Pelican. Pelican is accessible via the Alaska ferry system, as well as floatplane from Juneau or Sitka (ADF&G 1994).

The population of Pelican, which grew by 67 percent between 1970 and 1990, decreased by 27 percent between 1990 and 2000. The population continued to decline in the first part of this decade, decreasing by 48 people or 29 percent between 2000 and 2005. Total estimated population was 106 in Pelican in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	133	180	222	163	115	106

Source: USDA Forest Service, 1997a; U.S. Census Bureau, 2001; Alaska DOL, 2007a

The Pelican economy is primarily based on commercial fishing (41 residents hold permits) and seafood processing. Pelican Seafoods, the largest employer, operates a seafood processing plant, the electric utility, a fuel company, and a store. It was purchased by Kaioh Suisan, a Japanese firm, in 1989 and then closed in 1996. It was subsequently purchased by Kake Tribal Corporation and re-opened during the same year. The plant processes salmon, halibut, sable fish, rockfish, and dungenesss crab (Alaska DCED 2002).

There have been low levels of tourism in Pelican for some time but more recently with the decline in commercial fishing tourism has begun to play a more important role in the local economy (Dugan et al. 2006). Tourism in Pelican is primarily focused on sport fishing and marine wildlife viewing charters, with 12 marine charters operating out of the town in 2005. The town also serves as a jumping-off point for independent travelers accessing nearby wilderness.

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. Approximately 8 percent of the labor force in Pelican was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $48,750, compared to a regional median of $44,118 (Alaska DCED 2002).

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Pelican is part of the North Chichagof community group, which also includes Elfin Cove and Hoonah (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record. Manufacturing and non-federal government were the major employers in the North Chichagof community group in 1999, accounting for 34 and 30 percent of total employment, respectively. Logging and seafood processing accounted for 24 and 10 percent of total employment, respectively.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Pelican in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-21. This area contains 488,851 acres of National Forest System land (among other land ownerships). Table 3.23-43 shows how the lands within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs account for less than one percent of the lands in the Pelican community use area under Alternative 5 (No Action). The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The main difference between the alternatives is the amount of acres allocated to development LUDs. Under Alternatives 4 and 7, approximately 5 percent of the area would be allocated to development LUDs, compared to less than 1 percent under Alternatives 2, 3, 5, and 6 and zero under Alternative 1.

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

Economy
Pelican is primarily a commercial fishing and seafood processing town. Employment within the community is expected to remain stable as long as the Pelican Seafoods plant continues to operate. Commercial fishing is not expected to be significantly affected under any of the alternatives.

Subsistence
In terms of subsistence use, Lisianski Inlet, Icy Strait, northwest Chichagof, and Yakobi Island are the most important areas to Pelican. These areas are presently legislatively withdrawn from timber harvest as either Wilderness or LUD II or allocated to the Mostly Natural LUDs. Therefore, it is unlikely that subsistence use in Pelican would be directly affected under any of the alternatives.

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 63 percent of the total edible pounds of subsistence resources harvested by Pelican households (Kruse and Frazier, 1988). Marine resources (fish and marine invertebrates) accounted for 64 percent of per capita subsistence harvest in Pelican in 1987.

The 1988 TRUCS study found that deer account for 30 percent of the total edible pounds of subsistence resources harvested by Pelican households (Kruse and Frazier, 1988). Deer accounted for 30 percent of per capita subsistence harvest by Pelican residents in 1987 (ADF&G 2006).

The WAAs used by Pelican residents for hunting deer lie within Game Management Unit (GMU) 4. Deer harvest in GMU 4 is considered very high relative to other areas of Southeast Alaska, which is indicative of relatively high deer populations (ADF&G 2005). Over 1997-2004, there has been no significant trend in the number of deer harvested or in the number of hunters (ADF&G 2005). As noted above, the number of residents in Pelican decreased by 29 percent from 2000 to 2005.

Pelican residents take the majority (94 percent) of their deer from three WAAs on northwestern Chichagof Island (3417, 3418, and 3419). As shown in Table 3.23-44, these WAAs would not be affected by any of the alternatives because they are in wilderness, LUD II areas, or are in other Non-development LUDs.

Table 3.23-44
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Pelican Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability							
WAA	Pelican Residents	All Rural Hunters	All Hunters	2005	Alt 1	Alt 2	Alt 3	Alt 4	Alt 5	Alt 6	Alt 7
3418	37	62	70	100	100	100	100	100	100	100	100
3419	35	35	47	100	100	100	100	100	100	100	100
3417	28	100	159	100	100	100	100	100	100	100	100

*Calculated based on harvest where location is known.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that the 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide sufficient habitat capability for deer hunted in the Pelican community use area by Pelican residents, all rural hunters, and all hunters in the short term and long term.

In summary, use of most subsistence resfources (fish and marine invertebrates) by Pelican residents is not expected to be affected under any of the alternatives. In addition, subsistence use of deer by Pelican households would not be directly affected by any of the alternatives as the areas most heavily used by Pelican. Marine resources (fish and marine invertebrates) accounted for 64 percent of per capita subsistence harvest in Pelican in 1987.

Petersburg and Kupreanof

Petersburg is located on the northern tip of Mitkof Island across Wrangell Narrows from Kupreanof Island. It lies midway between Juneau and Ketchikan, about 120 miles from either community. According to the 2000 Census, Petersburg had a 2000 population of 3,224, with Alaska Natives comprising 7 percent of the total (U.S. Census Bureau 2001). The community of Kupreanof, with a population of 23 in 2000, is located less than one mile from Petersburg, on Kupreanof Island. This settlement is economically tied to Petersburg, where most residents find employment, purchase goods, and attend school (ADF&G 1994).

Prior to Petersburg's development by homesteaders and fishermen around 1900, Tlingit use of the area occurred at many small settlements (ADF&G 1994). The community of Petersburg was founded by Norwegian Peter Buschmann in 1899 and incorporated in 1906. More Norwegians followed and settled into a Scandinavian-style community. Petersburg has a local Fish and Game Advisory Committee, which takes an active interest in resource management issues (ADF&G 1994).

The population of Petersburg, which increased by 57 percent between 1970 and 1990, increased by less than 1 percent between 1990 and 2000. The population decreased by 69 people or 2 percent between 2000 and 2005. Total estimated population was 3,129 in Petersburg in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	2,042	2,821	3,207	3,224	3,155	3,129

Source: USDA Forest Service 1997a; U.S. Census Bureau 2001; Alaska DOL 2007a

The Petersburg economy is primarily based on the commercial fishing (469 residents have commercial fishing permits) and timber industries and, unlike the rest of Southeast Alaska, has escaped the severe swings in economic cycles. Estimated gross fishing revenues of local residents was almost $22 million in 2000. Petersburg is among the top-ranked ports in the United States for quality and value of fish landed. The city includes several processors operating cold storage, canneries, and custom packing services and the state-run Crystal Lake salmon hatchery. Petersburg also provides supplies and services for many of the area logging camps. While there is no deep water dock suitable for cruise ships, there is independent sportsmen and tourist visitation (Alaska DCED, 2002).

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. Approximately 10 percent of the labor force in Petersburg was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $49,028, compared to a regional median of $44,118 (Alaska DCED, 2002).

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Petersburg and Kupreanof are part of the Petersburg community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record.

Non-federal government and seafood processing were the main employers in the Petersburg community group in 1999, accounting for 25 and 24 percent of total employment, respectively. Employment in the wood products sector declined by 93 percent between 1990 and 1999, with just 5 people employed in this sector in 1999. Three sawmills, The Mill, Alaska Fibre, and Southeast Alaska Wood Products, were identified in Petersburg in the mill survey conducted for the Forest Service in 2006. The mill survey noted that Alaska Fibre sold its primary processing equipment in 2005, but reportedly has plans to purchase and install new equipment (Juneau Economic Development Council 2007). According to the 2006 mill survey, The Mill and Southeast Alaska Wood Products had respective installed production capacities of 8.5 MMBF and 4.5 MMBF, and together processed approximately 250 MBF in 2006 and employed 2 people (Juneau Economic Development Council 2007).

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Petersburg in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-22. This area contains 742,197 acres of National Forest System land (among other land ownerships). Table 3.23-45 shows how the lands within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs presently account for about 40 percent of the total acreage within the Petersburg community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 through 3. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 30 percent under Alternative 5 (No Action) to 58 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-45). Alternatives 4 and 7 would increase the acreage in development LUDs.

Figure 3.23-22
Petersburg's Community Use Area

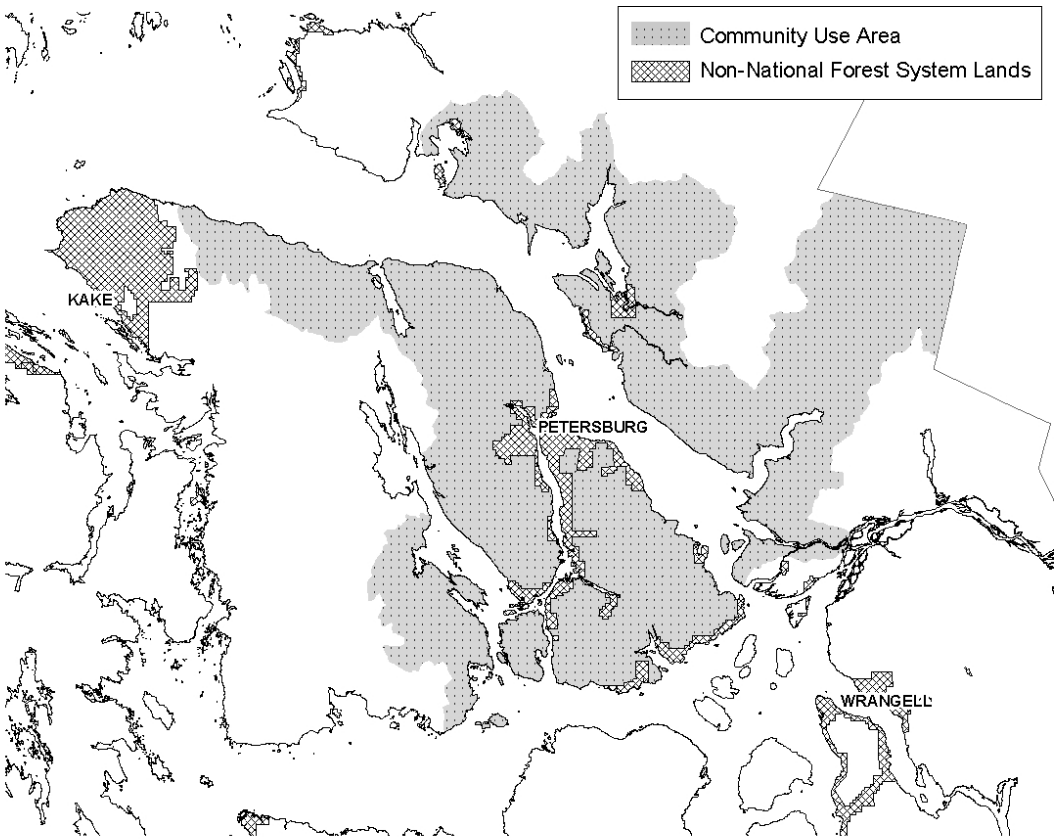

Table 3.23-45
LUD Groups in Petersburg's Community Use Area by Alternative

	Alternative						
	1	2	3	4	5	6	7
	Suitable National Forest System Acres for Timber Management						
Suitable Acres	37,346	64,756	80,848	99,068	86,229	86,177	115,610
LUD Groups	**Acres of National Forest System Land per LUD Group**						
Wilderness/National Monument	223,285	223,285	223,285	223,285	223,285	223,285	223,285
Mostly Natural	432,243	336,442	251,709	170,174	223,095	233,287	125,381
Moderate Development	45,518	100,014	147,536	195,479	162,219	160,680	220,238

Total	**742,197**	**742,197**	**742,197**	**742,198**	**742,198**	**742,197**	**742,205**

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

Development LUDs would account for 47 percent and 53 percent under Alternatives 4 and 7, respectively, compared to 40 percent under Alternative 5.

Total suitable acres would range from 5 percent under Alternative 1 to 16 percent under Alternative 7, compared to 12 percent of the total community use area under Alternative 5 (No Action) and Alternative 6 (Proposed Action).

Economy

Commercial fishing is particularly important to Petersburg. Commercial fisheries employment is not likely to be affected under any of the alternatives. Southeast Alaska Wood Products had 1.7 MMBF under contract with the Forest Service in August 2006. This volume would not be affected under any of the alternatives. Approximately 20.6 MMBF is presently under contract in the Petersburg Ranger District in August 2006. About 4.6 MMBF of this volume would be affected under Alternative 1, which would maintain all Inventoried Roadless Areas on the Tongass in a natural condition and not permit timber harvest in these areas. None of the other alternatives would affect this volume. These data provide an indication of potential impacts, actual impacts would depend on the volume that is under contract when the decision is implemented and whether potentially affected existing sales were cancelled as part of the decision.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 52 percent of the total edible pounds of subsistence resources harvested by Petersburg households (Kruse and Frazier, 1988). Marine resources (fish and marine invertebrates) accounted for 65 percent of per capita subsistence harvest in Petersburg in 1987.

The 1988 TRUCS study found that deer accounted for 21 percent of the total edible pounds of subsistence resources harvested by Petersburg households (Kruse and Frazier 1988). Deer accounted for 22 percent of per capita subsistence harvest by Petersburg residents in 1987 (ADF&G 2006).

Petersburg residents harvest deer on and around Mitkof and Kupreanof Islands, with the majority of harvest occurring within GMUs 3 and 4. Deer harvest in GMU 3 declined between 1998-2002 and increased between 2002-2004. The number of deer hunters declined between 2000-2002 and slightly increased between 2002-2004 (ADF&G 2005). Deer harvest in GMU 4 is considered very high relative to other areas of Southeast Alaska, which is indicative of relatively high deer populations (ADF&G 2005). Over 1997-2004, there has been no significant trend in the number of deer harvested or in the number of hunters (ADF&G 2005). As noted above, the human population of Petersburg declined by an estimated 2 percent between 2000 and 2005. Petersburg had an estimated human population of 3,155 in 2005.

Eight WAAs account for the majority (78 percent) of deer harvest by Petersburg residents. As shown in Table 3.23-46, the Petersburg portion represents about three-quarters of the total and rural hunter harvest in these WAAs.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that the 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide sufficient habitat capability for deer hunted by Petersburg residents in the short term and long term. There was also sufficient habitat capability for deer hunted in the Petersburg community use area by all rural hunters in both the short term and long

Table 3.23-46
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Petersburg Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability

*Calculated based on harvest where location is known.

term. Projected deer harvest for all hunters would exceed 10 percent habitat capability, the level that the analysis assumed would provide a reasonably high level of hunter success for their effort, in the long term. The Final EIS analysis concluded that at some point a restriction in hunting might be necessary.

In summary, use of most subsistence resources by Petersburg residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives. However, subsistence use of deer in some of the WAAs hunted by Petersburg residents may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1. The risks of this occurring are greatest under Alternative 7 because of its general lack of Non-Development LUDs within the Petersburg use area, and lower under the other six alternatives. The risk of hunting restrictions would be reduced somewhat, through more intensive management (e.g., thinning) of the existing and future closed-canopy, young-growth forests in this area. Indirect effects associated with increased competition for deer within Petersburg's subsistence use areas could also occur under all alternatives due to displacement of hunters from other communities due to timber harvest activity. Additional road development under the alternatives would improve access but may increase competition with other non-local hunters.

Point Baker

Point Baker is located on the northern tip of Prince of Wales Island, 101 air miles northwest of Ketchikan. Point Baker received its name in 1793 from Captain George Vancouver. According to the 2000 Census, Point Baker had a 2000 population of 35, with Alaska Natives comprising 3 percent of the total (U.S. Census Bureau 2001).

Native settlement of the area was already established during Vancouver's time. Tlingits used fish camps at Point Baker to participate in both customary trade and subsistence fishing. Commercial fishing at Point Baker began in the early 1900s, when the area was used as the site of a floating fish packer. Land sales in Point Baker accounted for part of an increase in year-round residents, the majority being non-Native (ADF&G 1994).

Point Baker is accessible by floatplane and skiff. Point Baker is not an incorporated city, nor is it within any other local government jurisdiction. It is not part of any

Native organization and has no traditional council. The town is not recognized under the Alaska Native Claims Settlement Act. Residents of Point Baker are members of the Sumner Strait Fish and Game Advisory Committee (ADF&G 1994).

The population of Point Baker, which decreased by about a half between 1970 and 1990, was fairly constant between 1990 and 2000. The population decreased by an estimated 13 people or 37 percent between 2000 and 2005. Total estimated population was 16 in Point Baker in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	80	90	39	35	22	16

Source: USDA Forest Service, 1997a; U.S. Census Bureau, 2001; Alaska DOL, 2007a

The Point Baker economy is heavily dependent on the fishing industry, with three quarters of the population holding commercial fishing permits (Alaska DCED 2002).

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. These data are an extrapolation based on information from a sample of residents. An extrapolation of a small sample may have inaccuracies but should provide a general indication of the distribution of employment. The 2000 U.S. Census estimated that 15 residents are employed. While no adults in Point Baker were identified as unemployed and seeking work in 2000, 58 percent of the population was identified as not employed and not seeking work. Median household income was $28,000, compared to a regional median of $44,118 (Alaska DCED 2002).

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Point Baker is part of the North Prince of Wales community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record. Wood products employment in the North Prince of Wales community group declined by 186 jobs or 69 percent between 1990 and 1999. Wood products employment accounted for 83 jobs or 23 percent of total employment in this community group in 1999.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Point Baker in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-23. This area contains 842,636 acres of National Forest System land (among other land ownerships). Table 3.23-47 shows how the lands within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs presently account for 43 percent of the total acreage within the Point Baker community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 through 3. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 48 percent under Alternative 5 (No Action) to 64 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-47). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 52 percent and 61 percent under Alternatives 4 and 7, respectively, compared to 43 percent under Alternative 5.

Total suitable acres would range from 13 percent under Alternative 1 to 25 percent under Alternative 7, compared to 17 percent of the total community use area under Alternative 5 (No Action) and Alternative 6 (Proposed Action).

Economy

Commercial fisheries and subsistence use are important to Point Baker. Commercial fisheries employment is not likely to be affected under any of the alternatives.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 59 percent of the total edible pounds of subsistence resources harvested by Point Baker households (Kruse and Frazier, 1988). Marine resources (fish and marine invertebrates) accounted for 79 percent of per capita subsistence harvest in Point Baker in 1996.

The 1988 TRUCS study found that deer account for 27 percent of the total edible pounds of subsistence resources harvested by Point Baker households (Kruse and Frazier 1988). Deer accounted for 16 percent of per capita subsistence harvest by Point Baker residents in 1996 (ADF&G 2006).

Point Baker residents harvest deer on north Prince of Wales Island and Kupreanof Island, which are included in GMUs 2 and 3, respectively. Deer harvest and hunter effort in GMU 2 generally increased during 1997-2000 and subsequently declined during 2000-2004; however, no change has been noted in the average number of hunter-days required to harvest a deer (ADF&G 2005). Deer harvest in GMU 3 declined between 1998-2002 and increased between 2002-2004. The number of deer hunters declined between 2000-2002 and slightly increased between 2002-2004 (ADF&G 2005). Point Baker had a total estimated population of 22 people in 2005, 13 fewer people than in 2000.

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

Residents of Point Baker harvest the majority (72 percent) of their deer from two WAAs on north Prince of Wales Island (1529) and Kupreanof Island (5134). As shown in Table 3.23-48, the Point Baker portion ranges from 6 percent to 19 percent of the total harvest and from 3 percent to 16 percent of the rural hunter harvest in these WAAs. About 41 percent of the combined harvest in these WAAs is by non-rural hunters, suggesting that there is a harvest buffer that could be restricted, if necessary, before restrictions are placed on rural harvests.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that the 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, selected alternative (Alternative 11 in the 1997 Forest Plan EIS) should be able to provide sufficient habitat capability for deer hunted by Point Baker residents in the short term and long term. There was also sufficient habitat capability for deer hunted in the Point Baker community use area by all rural hunters in both the short term and long term. Projected deer harvest for all hunters would exceed 10 percent habitat capability, the level that the analysis assumed would provide a reasonably high level of hunter success for their effort, in the long term. The Final EIS analysis concluded that at some point a restriction in hunting might be necessary.

In summary, use of most subsistence resources by Point Baker residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives. However, subsistence use of deer on Prince of Wales Island may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1. The risks of this occurring are greatest under Alternative 7 because of its general emphasis on Development LUDs within the Point Baker use area, and lower under the other six alternatives. The risk of hunting restrictions would be reduced somewhat, through more intensive management (e.g., thinning) of the existing and future closed-canopy, young-growth forests in this area. Indirect effects associated with increased competition for deer within Point Baker's subsistence use areas on Prince of Wales Island could also occur under all alternatives due to displacement of hunters from other communities due to timber harvest activity. Additional road development under the alternatives would improve access but may increase competition with other non-local hunters. The level of road development is already relatively high in one of the WAAs most used by Point Baker residents (1529), with an existing open and total road densities of 0.9 and 1.5 miles per square mile, respectively. Road densities are very low in the other WAAs (5014 and 5134) important to Point Baker subsistence deer hunters. Long-term (100+ years) road development would vary by alternative and would result in estimated

Table 3.23-48
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Point Baker Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability							
WAA	Point Baker Residents	All Rural Hunters	All Hunters	2005	Alt 1	Alt 2	Alt 3	Alt 4	Alt 5	Alt 6	Alt 7
1529	7	122	226	73	63	61	60	56	59	59	50
5134	6	33	39	92	92	92	89	83	87	87	83
5014	2	4	4	96	96	96	96	70	75	75	64

*Calculated based on harvest where location is known.

maximum total road densities ranging from 0.1 to 1.7 mile per square mile in these three WAAs under Alternative 1, to 0.3 to 2.5 miles per square mile in these WAAs under Alternative 7 (for all ownerships combined).

Port Alexander

Port Alexander is located on the southern tip of Baranof Island about 85 miles south of Sitka. According to the 2000 Census, Port Alexander had a 2000 population of 81, with Alaska Natives comprising 4 percent of the total (U.S. Census Bureau 2001).

Port Alexander was named in 1849 by the governor of the Russian American colonies. In 1913, salmon trollers discovered the rich fishing grounds in the area, and two floating processors arrived soon after. By 1916, there was a fishing supply store, a shore station, and a bakery at Port Alexander. During the 1920s and 1930s, a prosperous fishing fleet evolved, and houses, stores, restaurants, and a school were constructed. The 1940s and 1950s saw a steep decline in Port Alexander's population. Today, people choose Port Alexander as a home because of its independent, subsistence lifestyle, and commercial fishing opportunities, as well as its remote setting. There are no roads in Port Alexander; travel within the community is by skiff, boardwalks, and footpaths (ADF&G 1994). The community has a local Fish and Game Advisory Committee.

Port Alexander's population, which was three times larger in 1990 than it was in 1970, decreased by 32 percent (39 residents) between 1990 and 2000. The population stayed relatively constant between 2000 and 2005, decreasing by an estimated 6 people over this period. Total estimated population was 64 in Port Alexander in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	36	86	119	81	75	64

Source: USDA Forest Service 1997a; U.S. Census Bureau 2001; Alaska DOL 2007a

The economy of Port Alexander is largely based on commercial fishing and subsistence use of marine and forest resources. More than 40 percent of the population hold commercial fishing permits (35 residents). The City, the school, and post office provide the only full time employment in the area (Alaska DCED 2002).

Employment by industry data for Port Alexander is not included since it was based on a very small sample size and may not be a good indicator of the economy as a whole. The 2000 U.S. Census identified 29 residents of Port Alexander as being employed out of a potential work force (aAge 16+) of 48. Approximately 9 percent of the labor force in Port Alexander was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $31,563 compared to a regional median of $44,118 (Alaska DCED 2002).

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Port Alexander is part of the Kuiu Island community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record. Logging employment accounted for 91 percent of total employment (77 jobs) in this community group in 1990. There was no logging employment in this community group in 1999, and the non-federal government sector accounted for 13 of the 14 recorded jobs.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Port Alexander in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-24. This area contains 86,828 acres of National Forest System land (among other land ownerships). Table 3.23-49 shows how the lands within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

None of Port Alexander's community use area is presently allocated to development LUDs and this would be the case under all the alternatives evaluated in this EIS. There would be no change in the LUD allocation for this community under any of the alternatives.

Economy

Port Alexander is primarily a commercial fishing town. Commercial fishing and subsistence use are important to the community. Commercial fishing is not expected to be significantly affected under any of the alternatives.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 55 percent of the total edible pounds of subsistence resources harvested by Port Alexander households (Kruse and Frazier 1988). Marine resources (fish and marine invertebrates) accounted for 55 percent of per capita subsistence harvest in Port Alexander in 1987.

Deer account for 36 percent of the total edible pounds of subsistence resources harvested by Port Alexander households (Kruse and Frazier, 1988). Deer accounted for 35 percent of per capita subsistence harvest by Port Alexander residents in 1987 (ADF&G 2006).

Port Alexander residents take the majority (95 percent) of their deer from one WAA (3734) on the south end of Baranof Island. This WAA is located within GMU 4. Deer harvest in GMU 4 is considered very high relative to other areas of Southeast Alaska, which is indicative of relatively high deer populations (ADF&G 2005). Over 1997-2004, there has been no significant trend in the number of deer harvested or in the number of hunters (ADF&G 2005). Port Alexander's human population declined slightly between 2000 and 2005.

As shown in Table 3.23-50, WAA 3734 would not be affected under any of the alternatives.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that the 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide sufficient habitat capability for deer hunted in the Port Alexander community use area by Port Alexander residents, all rural hunters, and all hunters in the short term and long term.

*Calculated based on harvest where location is known.

In summary, use of most subsistence resources (fish and marine invertebrates) by Port Alexander residents is not expected to be affected under any of the alternatives. In addition, subsistence use of deer by Port Alexander households would not be directly affected by any of the alternatives as the area most heavily used by Port Alexander residents is in Non-development LUDs. It is also unlikely that Port Alexander residents would be affected by increased competition or access because of the limited access and the lack of activities under the alternatives in this area.

Port Protection

Port Protection, located on the northern end of Prince of Wales Island in a quiet bay facing Sumner Strait, is only accessible by air and water. The nearby logging camp site at Labouchere Bay, however, is a roaded port. The community's setting along the waterfront of the cove requires skiff travel for most purposes (ADF&G 1994).

Port Protection is not an incorporated city, nor is it within any local government jurisdiction. Residents of Port Protection are members of the Sumner Strait Fish and Game Advisory Committee (ADF&G 1994). According to the 2000 Census, Port Protection had a 2000 population of 63, none of whom were Alaska Natives (U.S. Census Bureau 2001).

Port Protection was first reported to the western world by the English explorer George Vancouver in 1793. Signs of earlier indigenous occupation of the northern shoreline of Prince of Wales Island include stone and wooden stake fish weirs and traps, as well as shell middens of edible marine invertebrates (ADF&G 1994).

A scow served as a fish-buying station until it was replaced in 1946 by a trading post. A long float dock accommodated many fishing boats at the post (ADF&G 1994).

The population of Port Protection, which increased by approximately 50 percent between 1980 and 1990, was approximately the same in 2000 as it was in 1990. The population decreased by an estimated 9 people or 14 percent between 2000 and 2005. Total estimated population was 59 in Port Protection in 2006 (Alaska DOL 2007a).

Year	1980	1990	2000	2005	2006
Population	40	62	63	54	59

Source: USDA Forest Service, 1997a; U.S. Census Bureau, 2001; Alaska DOL, 2007a

The Port Protection economy peaks during the fishing season in summer and fall. Fourteen residents hold a commercial fishing permit and some residents provide sport fishing charters. Local residents depend on subsistence for year-round support (Alaska DCED 2002; 2006).

The 2000 U.S. Census identified a potential work force of 61 residents and total employment of 34. Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. These data is extrapolated from a sample of the city population. Because the sample size was small, the extrapolation is not accurate in detail, but should provide a general indication of distribution of employment. While no adults in Port Protection were unemployed and seeking work in 2000, 44 percent were unemployed and not seeking work. Median household income was $10,938, compared to a regional median of $44,118 (Alaska DCED 2002).

Total Employment	**91**	**100**

Source: Alaska DCED 2002

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Port Protection is part of the North Prince of Wales community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record. Wood products employment in the North Prince of Wales community group declined by 186 jobs or 69 percent between 1990 and 1999. Wood products employment accounted for 83 jobs or 23 percent of total employment in this community group in 1999.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Port Protection in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-25. This area contains 706,627 acres of National Forest System land (among other land ownerships). Table 3.23-51 shows how the lands within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs presently account for 49 percent of the total acreage within the Port Protection community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan.

Figure 3.23-25
Port Protection's Community Use Area

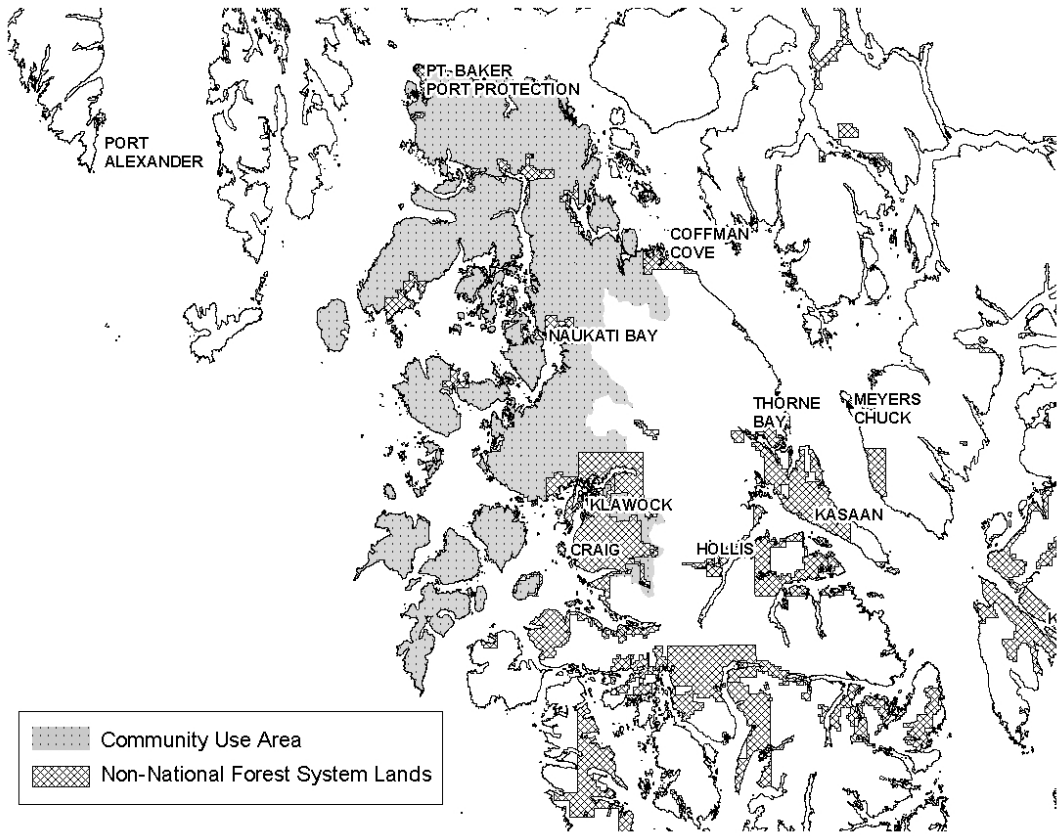

Table 3.23-51
LUD Groups in Port Protection's Community Use Area by Alternative

	Alternative						
	1	**2**	**3**	**4**	**5**	**6**	**7**
	Suitable National Forest System Acres for Timber Management						
Suitable Acres	108,469	120,049	127,290	135,243	134,817	129,563	180,164
LUD Groups	**Acres of National Forest System Land per LUD Group**						
Wilderness/National Monument	17,019	17,019	17,019	17,019	17,019	17,019	17,019
Mostly Natural	474,390	407,001	367,958	320,675	345,451	353,087	245,932
Moderate Development	48,236	58,268	78,759	81,614	81,785	82,807	116,805
Intensive Development	166,980	224,338	242,892	287,321	262,373	253,714	326,871
Total	**706,625**	**706,626**	**706,628**	**706,629**	**706,628**	**706,626**	**706,627**

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 through 3. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 49 percent under Alternative 5 (No Action) to 64 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-51). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 53 percent and 64 percent under Alternatives 4 and 7 compared to 49 percent under Alternative 5.

Total suitable acres would range from 17 percent under Alternative 1 to 25 percent under Alternative 7, compared to 19 percent under Alternative 5 (No Action).

Economy

Port Protection's economy primarily depends upon commercial fishing. Subsistence use is also important in this community. Commercial fisheries employment is not likely to be affected under any of the alternatives.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. Marine resources (fish and marine invertebrates) accounted for 69 percent of per capita subsistence harvest in Port Protection in 1996.

Deer accounted for 21 percent of per capita subsistence harvest by Port Protection residents in 1996 (ADF&G 2006).

Port Protection residents take the majority (95 percent) of their deer from one WAA (1529) on the north end of Prince of Wales Island. This WAA is located within GMU 2. Deer harvest and hunter effort in GMU 2 generally increased during 1997-2000 and subsequently declined during 2000-2004; however, no change has been noted in the average number of hunter-days required to harvest a deer (ADF&G 2005). Port Protection's population declined slightly between 2000 and 2005.

As shown in Table 3.23-52, the Port Protection portion of harvest represents about 4 percent of the total harvest and about 8 percent of the rural hunter harvest in WAA 1529. About 46 percent of the harvest in this WAA is by non-rural hunters, suggesting that there is a harvest buffer that could be restricted, if necessary, before restrictions are placed on rural harvests.

WAA 1529 occurs in an area with substantial past harvest and, therefore, deer habitat capabilities are currently estimated to be considerably below 1954 levels (Table 3.23-52). Under each of the alternatives, additional harvest would occur that would reduce habitat capabilities after 100+ years to 50-63 percent of 1954 levels (Table 3.23-52).

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that the 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide sufficient habitat capability for deer hunted by Port Protection residents and by all hunters in the short-term. In the long-term, the affected WAAs may not be able to provide deer for all hunters.

Table 3.23-52
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Port Protection Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

1529	10	122	226	73	63	61	60	56	59	59	50

*Calculated based on harvest where location is known.

In summary, use of most subsistence resources by Port Protection residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives. However, subsistence use of deer may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1. The risks of this occurring are greatest under Alternative 7 because of its general emphasis on Development LUDs within the Port Protection use area, and lower under the other six alternatives. The risk of hunting restrictions would be reduced somewhat, through more intensive management (e.g., thinning) of the existing and future closed-canopy, young-growth forests in this area. Indirect effects associated with increased competition for deer within Port Protection's subsistence use areas could also occur under all alternatives due to displacement of hunters from other communities due to timber harvest activity. Additional road development under the alternatives would improve access but may increase competition with other non-local hunters. The level of road development is already relatively high in this WAA. Existing open road density is 0.9 mile per square mile and existing total road density is 1.5 miles per square mile, respectively (all ownerships combined). Long-term (100+ years) road development would vary by alternative and would result in an estimated maximum total road density of 1.7 mile per square mile under Alternative 1, to 2.0 miles per square mile under Alternative 7 (for all ownerships combined).

Saxman

Saxman is located on west Revillagigedo Island on the Tongass Highway, about three miles south of Ketchikan. According to the 2000 Census, Saxman had a 2000 population of 431, with Alaska Natives comprising 66 percent of the total (U.S. Census Bureau 2001).

In 1894, Tlingits from the old Cape Fox and Tongass villages chose Saxman as the site for a new village in which to locate a government school and a new Presbyterian church. The Saxman people are also known as the Cape Fox people or Sanya in the earlier ethnographies. Saxman was incorporated in 1929 and was certified by the federal government as a second class municipal corporation. Three years later, the federal government issued a patent to 365 acres of land to the townsite trustee for Saxman (ADF&G 1994).

When the Ketchikan Gateway Borough was formed in 1963, Saxman was included within its boundaries. In 1971 and 1973, respectively, Saxman was recognized and then certified as a Native village under the Alaska Native Claims Settlement Act. An elected mayor and six city council members constitute the governing body of the municipality as organized under state law. The community has a local Fish and Game Advisory Committee (ADF&G 1994).

When the Tlingits left their old villages to move to Saxman, they abandoned houses, totems, carvings, and other cultural and ceremonial artifacts. In 1938, the Civilian Conservation Corps retrieved and brought to Saxman original totems from the abandoned villages and cemeteries of Tongass, Cat, and Pennock Islands, and Cape Fox. The Totem Park in Saxman has become a major attraction for Ketchikan area visitors (ADF&G 1994).

The population of Saxman, which more than doubled between 1970 and 1990, increased by 17 percent between 1990 and 2000. The population decreased by 26 people or 6 percent between 2000 and 2005. Total estimated population was 422 in Saxman in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	135	273	369	431	405	422

Source: USDA Forest Service, 1997a; U.S. Census Bureau, 2001; Alaska DOL, 2007a

Most employment opportunities for Saxman residents are in the city of Ketchikan. The City of Saxman, the Saxman Seaport, and the Cape Fox Corporation provide employment for a number of local residents. The Saxman Totem Park with a tribal house, a carving center, and a cultural hall for traditional Tlingit dance, has become an attraction for Ketchikan area visitors (Alaska DCED 2002).

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. Approximately 26 percent of the labor force in Saxman was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $44,375, compared to a regional median of $44,118 (Alaska DCED 2002).

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Saxman is located in the Ketchikan Ranger District and is part of the Ketchikan community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Saxman in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-26. This area contains 1,975,123 acres of National Forest System land (among other land ownerships). Table 3.23-53 shows how the lands within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs presently account for 21 percent of the total acreage within the Saxman community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 and 2. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 31 percent under Alternative 5 (No Action) to 48 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-53). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 32 percent and 33 percent under Alternatives 4 and 7, respectively, compared to 21 percent under Alternative 5.

Total suitable acres would range from 2 percent under Alternative 1 to 10 percent under Alternative 7, compared to 6 percent of the total community use area under Alternative 5 (No Action) and Alternative 6 (Proposed Action).

Economy

Saxman, a traditional native community, could be affected primarily by changes in recreation and tourism use, commercial fishing, timber processing, and subsistence opportunities.

Approximately 42.8 MMBF was under contract in the Ketchikan Ranger District in August 2006. About 75 percent (32.1 MMBF) of this volume could be potentially affected under Alternative 1, which would maintain all Inventoried Roadless Areas on the Tongass in a natural condition and not permit timber harvest in these areas. None of the other alternatives would affect this volume. These data provide an indication of potential impacts, actual impacts would depend on the volume that is under contract when the decision is implemented and whether potentially affected existing sales were cancelled as part of the decision.

Commercial fisheries employment is not likely to be affected under any of the alternatives. Recreation and tourism in Saxman is also unlikely to be affected under any of the alternatives.

Subsistence

No significant decline in salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 68 percent of the total edible pounds of subsistence resources harvested by Saxman households (Kruse and Frazier, 1988). Marine resources (fish and marine invertebrates) accounted for 71 percent of per capita subsistence harvest in Saxman in 1987.

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

The 1988 TRUCS study found that deer accounted for 19 percent of the total edible pounds of subsistence resources harvested by Saxman households (Kruse and Frazier 1988). Deer accounted for 18 percent of per capita subsistence harvest by Saxman residents in 1987 (ADF&G 2006).

Data were not provided separately for Saxman in the ADF&G deer harvest reports for 1996 to 2002. The majority of deer harvest by Saxman residents likely takes place in GMU 1A. Deer harvest in GMU 1A generally declined from 1997 to 2004, with the number of hunters and hunter effort also decreasing over this period (ADF&G 2005). As noted above, the population of Saxman decreased by an estimated 6 percent between 2000 and 2005. Saxman had an estimated population of 405 residents in 2005. Marine resources (fish and marine invertebrates) accounted for 71 percent of per capita subsistence harvest in Saxman in 1987.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that the 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide habitat capability for deer hunted in the Saxman community use area by Saxman residents, all rural hunters, and all hunters in the short term. This alternative was also estimated to provide sufficient habitat capability for Saxman residents and all rural hunters in the long term. However, projected deer harvest for all hunters was estimated to exceed 10 percent habitat capability, the level that the analysis assumed would provide a reasonably high level of hunter success for their effort, in the long term.

In summary, use of most subsistence resources by Saxman residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives. However, subsistence use of deer may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1. The risks of this occurring are greatest under Alternative 7, and second highest under Alternative 4 because of their lower use of Non-Development LUDs compared with the other alternatives. Alternatives 1, 2, and 3 would have the lowest risk and Alternatives 5 and 6 would be intermediate.

Sitka

Located on the west side of Baranof Island, Sitka is the only community in Southeast Alaska that fronts the open sea. According to the 2000 Census, Sitka had a 2000 population of 8,835, with Alaska Natives comprising 19 percent of the total (U.S. Census Bureau 2001).

Present-day Sitka was originally inhabited by a major tribe of Tlingits who called the village “Shee Atika.” Traditionally, the Tlingits used a wide area surrounding the community for hunting, fishing, and gathering wild resources. The site became “New Archangel” in 1799, the capital of Russian America (ADF&G 1994).

Sitka became the focal point of Russian fur trade in North America beginning in 1741. During the mid-1800s, Sitka was the major port on the north Pacific coast, with ships calling from many nations. After the purchase of Alaska by the United States in 1867, it remained the capital of the Territory until 1906, when the seat of government moved to Juneau. During the early 1900s gold mines contributed to its growth, and during World War II the town was fortified. After the war, the Bureau of Indian Affairs converted some of the buildings to a boarding school for Alaska Natives (ADF&G, 1994). The APC pulp mill operated in Sitka from 1959 through 1993, employing almost 400 people at the time of closure.

The population of Sitka, which grew by 41 percent between 1970 and 1990, increased by just 3 percent between 1990 and 2000, and 1 percent or an estimated 112 residents between 2000 and 2005. Total estimated population was 8,833 in Sitka in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	6,109	7,803	8,588	8,835	8,947	8,833

Source: USDA Forest Service, 1997a; U.S. Census Bureau, 2001; Alaska DOL, 2007a

Sitka has a diversified economy, with tourism, fishing, fish processing, government, health care services, transportation, and retail all contributing to its base. A total of 586 residents hold commercial fishing permits. Cruise ships contribute an estimated $11 million dollars to the local economy and residents realized an estimated $20 million in gross fishing revenue in 2002. Sound Seafood and Seafood Producers Co-op are major employers of local residents. Regional health care services and the U.S. Forest Service also employ a number of people (Alaska DCED 2002; 2006).

A study conducted by the Alaska DOL in 2003 suggested that Sitka's economy appears to have survived the downturn in its economy caused by the pulp mill closure, in large part because it has a relatively diversified economy (Gilbertson 2003). While the community of Sitka does not appear to have been as negatively affected by the closure of the pulp mill as some predicted, the effects have been felt by the workers who lost their jobs. By 2001, 57 percent of the former pulp mill labor force were no longer employed in Alaska, 43 percent had left the State, and 14 percent were in the State but had left the workforce, most likely retired. Only 25 percent of the former pulp mill workers were still living and working in Sitka (Gilbertson 2003).

Nature-based tourism in Sitka is less dominated by large cruise ships than in the other coastal communities with independent travelers making up a larger share of total visitors (Dugan et al. 2006). Multi-day fishing packages and kayaking and hunting are popular nature-based tourist activities operating from Sitka. An estimated 267,000 cruise ship passengers were scheduled to visit Sitka in 2006. There is no deepwater dock in Sitka so cruise ships anchor offshore and transport passengers to Sitka on smaller vessels.

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. Approximately 8 percent of the labor force in Sitka was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $51,901, compared to a regional median of $44,118 (Alaska DCED 2002).

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Sitka is part of the Sitka community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record.

Wood products employment declined from 404 in 1990 (10 percent of total employment) to 0 in 1999 in the Sitka community group. Services, non-federal government, and retail trade accounted for 31, 22, and 17 percent of total employment in 1999, with recreation-related activities accounting for 10 percent. A total of 206,279 cruise ship passengers visited Sitka in 2001, approximately 18 percent less than the number of passengers in 1996.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Sitka in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-27. This area contains 425,121 acres of National Forest System land (among other land ownerships). Table 3.23-54 shows how the lands within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs presently account for 22 percent of the total acreage within the Sitka community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 and 2. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 74 percent under Alternative 5 (No Action) to 96 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-54). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 59 percent of community use area acres under both of these alternatives compared to 22 percent under Alternative 5.

Total suitable acres would range from no acreage under Alternative 1 to 12 percent under Alternative 7, compared to 5 percent of the total community use area under Alternative 5 (No Action) and Alternative 6 (Proposed Action).

Economy

Commercial fishing, recreation and tourism, and subsistence are important to Sitka residents. Commercial fishing is not expected to be significantly affected under any of the alternatives. None of the alternatives are expected to affect recreation and tourism-related employment in Sitka.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 69 percent of the total edible pounds of subsistence resources harvested by Sitka households (Kruse and Frazier 1988). Marine resources (fish and marine invertebrates) accounted for 68 percent of per capita subsistence harvest in Sitka in 1996.

Total	**425,121**	**425,121**	**425,121**	**425,120**	**425,121**	**425,121**	**425,120**

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

The 1988 TRUCS study found that deer accounted for 27 percent of the total edible pounds of subsistence resources harvested by Sitka households (Kruse and Frazier, 1988). Deer accounted for 22 percent of per capita subsistence harvest by Sitka residents in 1996 (ADF&G 2006).

Sitka residents mainly harvest deer on Baranof Island, which is included in GMU 4. Deer harvest in GMU 4 is considered very high relative to other areas of Southeast Alaska, which is indicative of relatively high deer populations (ADF&G 2005). Over 1997-2004, there has been no significant trend in the number of deer harvested or in the number of hunters (ADF&G 2005). As noted above, the human population of Sitka increased by an estimated 1 percent between 2000 and 2005. Sitka had an estimated population of 8,947 in 2005.

Eleven WAAs account for the majority (76 percent) of deer harvest by Sitka residents. As shown in Table 3.23-55, the Sitka portion represents over 95 percent of the rural hunter harvest and almost 90 percent of the total harvest in these WAAs. About 6 percent of the combined harvest in these WAAs is by non-rural hunters, suggesting that there is very little harvest buffer that could be restricted, if necessary, before restrictions are placed on rural harvests.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that the 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, would not be able to provide sufficient habitat capability for deer hunted in the Sitka community use area by Sitka residents, all rural hunters, and all hunters in the short term. Sitka residents were identified as harvesting 15 percent of habitat capability a year, which exceeds 10 percent habitat capability, the level that the analysis assumed would provide a reasonably high level of hunter success for their effort. The Final EIS analysis concluded that at some point a restriction in hunting might be necessary.

In summary, use of most subsistence resources by Sitka residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives. However, subsistence use of deer in some of the WAAs hunted by Sitka residents may be affected to the point that some restriction in hunting might be necessary over the

*Calculated based on harvest where location is known.

long term, even under Alternative 1. The risks of this occurring are greatest under Alternative 7 because of its general lack of Non-Development LUDs within the Sitka use area, and lower under the other six alternatives. The risk of hunting restrictions would be reduced somewhat, through more intensive management (e.g., thinning) of the existing and future closed-canopy, young-growth forests in this area. Indirect effects associated with increased competition for deer within Sitka's subsistence, use areas could also occur under all alternatives due to displacement of hunters from other communities due to timber harvest activity. Additional road development under the alternatives would improve access but may increase competition with other non-local hunters.

Skagway

Skagway is located in northern Southeast Alaska at the head of Taiya Inlet, 95 air miles north of Juneau. It is the end-of-the line for the Alaska Marine ferry and the entrance to the Klondike Highway. According to the 2000 Census, Skagway had a 2000 population of 862, with Alaska Natives comprising 3 percent of the total (U.S. Census Bureau 2001).

Prior to the founding of the community, the area was settled by Chilkoot Tlingit who called it "Skagua," or "the place where the north wind blows." The Chilkoots controlled access into the interior along what has become known as the Chilkoot Trail, which follows along the Taiya River and over the Chilkoot Pass. The Chilkoot Trail was a major trade route for the Chilkoot Tlingit, interior Tlingit, and Athabaskans (ADF&G 1994).

Settlement began in Skagway in 1887 when a seafarer named William Moore decided to develop a trading and mining route into the Yukon Territory using the Chilkoot Trail. As the Klondike gold rush hit the area in 1896, the Chilkoot and White Pass trails became the major routes into the Interior. Within a few years, the trails were superseded by the adjacent White Pass and Yukon Railway. The railway continued to function as a supply and shipping route between Skagway and Whitehorse until 1982 (ADF&G 1994). The railway currently operates as a tourist attraction.

Skagway is incorporated as a first class city. The community participates in the Upper Lynn Canal Fish and Game Advisory Committee (ADF&G 1994). A total of 610,145 cruise ship passengers visited Skagway in 2001, more than double the number in 1996.

The population of Skagway, which declined between 1980 and 1990, increased by 170 people or 25 percent between 1990 and 2000. The population decreased by an estimated 28 residents or 3 percent between 2000 and 2005. Total estimated population was 854 in Skagway in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	675	814	692	862	834	854

Source: USDA Forest Service, 1997a; U.S. Census Bureau, 2001; Alaska DOL, 2007a

Skagway has a strong base in the tourism industry. It is a port of call for cruise ships and a transfer site for interior rail and bus tours. The State ferry also connects travelers to the rest of Southeast Alaska. More than 600,000 cruise ship passengers and numerous State ferry travelers visit Skagway each year. Skagway is also the site of trans-shipment of lead/zinc ore, fuel, and freight via the Port and Klondike Highway to and from Canada (Alaska DCED 2002; 2006).

Total Employment	**475**	**100**

Source: Alaska DCED 2002

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. Approximately 14 percent of the labor force in Skagway was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $49,375 compared to a regional median of $44,118 (Alaska DCED 2002).

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Skagway is part of the Skagway community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record. The retail trade, services, and non-federal government sectors were the major employers in the Skagway community group in 1999, accounting for 32, 20, and 17 percent of total employment, respectively. Recreation-related activities (lodging, restaurants, and recreation services) accounted for 25 percent of total employment, illustrating the importance of recreation and tourism for this area.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Skagway in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-28. This area contains 199,938 acres of National Forest System land (among other land ownerships). Table 3.23-56 shows how the lands within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3. Only 4 percent of the acres in the Skagway community use area would be allocated to development LUDs under Alternative 5 (No Action) and Alternative 6 (Proposed Action). There would be no acres allocated to development LUDs under Alternatives 1 and 2, and approximately 5 percent under Alternatives 4 and 7, with approximately 4 percent under Alternative 3. There would be no suitable acres under any of the alternatives.

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

There are no acres within the Skagway Community Use Area allocated to Wilderness/National Monument LUDs under any of the alternatives.

Economy

Recreation, tourism, and subsistence use are important to the community of Skagway. None of the alternatives are expected to affect recreation and tourism-related employment in Skagway.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 88 percent of the total edible pounds of subsistence resources harvested by Skagway households (Kruse and Frazier 1988). Marine resources (fish and marine invertebrates) accounted for 88 percent of per capita subsistence harvest in Skagway in 1987.

The 1988 TRUCS study found that deer account for only a small fraction of the total edible pounds of subsistence resources harvested by Skagway households (Kruse and Frazier, 1988). Deer accounted for 7 percent of per capita subsistence harvest by Skagway residents in 1987 (ADF&G 2006).

Skagway residents harvested very few deer from 1996-2002 (Table 3.23-57). Residents harvested an annual average of more than one deer in just four WAAs over this period. Three of these WAAs are located in GMU 4; the other is located in GMU 1C. Deer harvest in GMU 4 is considered very high relative to other areas of Southeast Alaska, which is indicative of relatively high deer populations (ADF&G 2005). Over 1997-2004, there has been no significant trend in the number of deer harvested or in the number of hunters (ADF&G 2005). GMU 1C has been characterized from 1997-2004 by substantial annual variation in deer harvest, with no evident long-term trend in harvest levels (ADF&G 2005).

Skagway residents take the majority (68 percent) of their deer from four WAAs: two on Baranof Island, one on south Chichagof Island, and one on Douglas Island (Table 3.23-57). These numbers are, however, somewhat misleading due to the overall low deer harvest levels.

Table 3.23-57
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Skagway Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability							
WAA	Skagway Residents	All Rural Hunters	All Hunters	2005	Alt 1	Alt 2	Alt 3	Alt 4	Alt 5	Alt 6	Alt 7
2722	3	5	261	100	100	100	100	88	100	100	100
3001	2	422	431	81	81	79	79	72	78	79	71
3002	2	318	329	69	69	68	68	67	68	68	67
3308	2	98	158	66	64	59	57	53	56	57	51

*Calculated based on harvest where location is known.

Three of the WAAs identified in Table 3.23-57 are in areas with substantial past harvest and deer habitat capabilities are currently estimated to be considerably below 1954 levels. Under each of the alternatives, additional harvest would further reduce habitat capabilities. Reductions would be smallest under Alternatives 1 and 2 and greatest under Alternative 7 in WAAs 3001, 3002, and 3308. There would only be a reduction in habitat capability under Alternative 4 in the other WAA (2722), used relatively heavily by Skagway residents.Marine resources (fish and marine invertebrates) accounted for 88 percent of per capita subsistence harvest in Skagway in 1987.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide sufficient habitat capability for deer hunted by Skagway residents and all rural hunters in the short term. However, it concluded that demand would exceed the capability of the habitat to produce deer populations sufficient to avoid effects on hunter success for all hunters in the long term.

In summary, use of most subsistence resources by Skagway residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives. However, subsistence use of deer may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1.

Tenakee Springs

Tenakee Springs is located 50 miles northeast of Sitka on the north shore of Tenakee Inlet (east Chichagof Island). According to the 2000 Census, Tenakee Springs had a 2000 population of 104, with Alaska Natives comprising 3 percent of the total (U.S. Census Bureau 2001). Tenakee Springs, accessible only by floatplane or boat, is a stop on the Alaska Marine Highway ferry system.

A Tlingit winter village site was located in the vicinity of the present-day harbor and a summer village was located across the Inlet at Kadashan Bay (ADF&G 1994). Early prospectors and fishermen came to the site to wait out the winters and enjoy the natural hot springs in Tenakee. Around 1895, a large tub and building were constructed to provide a warm bathing place. The 108-degree sulfur springs is the social focus of the community, with bathing times scheduled for men and women.

In 1904, E. Snyder bought a tract of land from a Tlingit resident, including a house located near the public bathhouse. The post office, established in 1903, used the name Tenakee. In 1928, the community's name was changed to Tenakee Springs. The community has a local Fish and Game Advisory Committee, and many residents practice a subsistence lifestyle, actively exchanging resources with neighbors (ADF&G 1994).

Tenakee Springs' population increased slightly between 1990 and 2000, and decreased slightly between 2000 and 2005. Total estimated population was 109 in Tenakee Springs in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	86	138	94	104	98	109

Source: USDA Forest Service, 1997a; U.S. Census Bureau, 2001; Alaska DOL, 2007a

While Tenakee Springs is often considered a retirement community, commercial fishing (18 residents have permits), and tourism are important sources of income. The City and local store are the primary employers (Alaska DCED 2002).

An estimated 25 percent of the homes in Tenakee Springs are second homes. Tourism activities are limited to two family-run marine charters and Tenakee Springs residents have been vocal in their opposition to tourism development (Dugan et al. 2006). The Chichagof Conservation Council commenting on the Draft EIS noted that small-scale, locally-owned businesses catering to independent travelers are a large part of the Tenakee Springs economy. Local residents opposed cruise ship development, not all tourism development.

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. Approximately 14 percent of the labor force in Tenakee Springs was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $33,125, compared to a regional median of $44,118 (Alaska DCED 2002).

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Tenakee Springs is part of the Chatham Strait community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record. The non-federal government, wood products, and services sectors were the major employers in the Chatham Strait community group in 1999, accounting for 49, 18, and 17 percent of total employment, respectively. The wood products employment was entirely in the logging sector.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Tenakee Springs in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-29. This area contains 196,031 acres of National Forest the System land (among other land ownerships). Table 3.23-58 shows how the lands within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs presently account for 60 percent of the total acreage within the Tenakee Springs community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 through 3. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 40 percent under Alternative 5 (No Action) to 93 percent under

Figure 3.23-29

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-58). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 71 percent and 77 percent under Alternatives 4 and 7, respectively, compared to 60 percent under Alternative 5.

Total suitable acres would range from 3 percent under Alternative 1 to 21 percent under Alternative 7, compared to 14 percent of the total community use area under Alternative 5 (No Action) and 13 percent under Alternative 6 (Proposed Action).

Economy

Tenakee Springs is primarily a commercial fishing, subsistence, and retirement community. The lands along Tenakee Inlet are some of the most important to the community. Kadashan and Trap Bay watersheds are legislated LUD II areas. These areas were designated in the Tongass Timber Reform Act, in part, because of their high value for subsistence use for Tenakee Springs residents.

Commercial fishing is not expected to be significantly affected by Forest Service activities during the next 10 years.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 55 percent of the total edible pounds of subsistence resources harvested by Tenakee Springs households (Kruse and Frazier 1988). Marine resources (fish and marine invertebrates) accounted for 53 percent of per capita subsistence harvest in Tenakee Springs in 1987.

The 1988 TRUCS study found that deer accounted for 39 percent of the total edible pounds of subsistence resources harvested by Tenakee Springs households (Kruse and Frazier, 1988). Deer accounted for 41 percent of per capita subsistence harvest by Tenakee Springs residents in 1987 (ADF&G 2006). The WAAs used by Tenakee Springs residents for hunting deer lie within GMU 4. Deer harvest in GMU 4 is considered very high relative to other areas of Southeast Alaska, which is indicative of relatively high deer populations (ADF&G 2005). Over 1997-2004, there has been no significant trend in the number of deer harvested or in the number of hunters (ADF&G 2005). However, as shown above, Tenakee Springs' human population decreased slightly from 2000 to 2005, with an estimated 98 residents identified in 2005.

Tenakee Springs residents take the majority (67 percent) of their deer from two WAAs on Chichagof Island (3627 and 3526). As shown in Table 3.23-59, the Tenakee Springs portion represents about 35 percent and 20 percent of the total harvest and about 72 percent and 74 percent of the rural hunter harvest in these WAAs, respectively. About 64 percent of the combined harvest in these WAAs is by non-rural hunters, suggesting that there is a harvest buffer that could be restricted, if necessary, before restrictions are placed on rural harvests.

WAAs 3627 and 3526 occur in an area with substantial past harvest and, therefore, deer habitat capabilities are currently estimated to be below 1954 levels (Table 3.23-59). Under each of the alternatives, additional harvest would occur that would reduce habitat capabilities after 100+ years to 61-70 percent of 1954 levels in WAA 3627 and 60-77 percent in WAA 3526.

Table 3.23-59
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Tenakee Springs Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability							
WAA	**Tenakee Springs Residents**	**All Rural Hunters**	**All Hunters**	**2005**	**Alt 1**	**Alt 2**	**Alt 3**	**Alt 4**	**Alt 5**	**Alt 6**	**Alt 7**
3627	25	35	72	76	70	67	65	62	64	65	61
3526	23	31	115	81	77	73	72	69	72	72	60
3629	11	16	43	91	91	89	85	75	79	80	73

*Calculated based on harvest where location is known.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide sufficient habitat capability over the short term for deer hunted by Tenakee Springs residents, all rural hunters, and all hunters. However, it concluded that all alternatives may have future inadequate habitat capability for the total deer hunter and at some point a restriction in hunting may be necessary.

In summary, use of most subsistence resources by Tenakee Springs residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives. However, subsistence use of deer may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1. The risks of this occurring are greatest under Alternative 7, and lower under the other six alternatives. The risk of hunting restrictions would be reduced somewhat, through more intensive management (e.g., thinning) of the existing and future closed-canopy, young-growth forests in this area.

Thorne Bay

Thorne Bay is located at the head of Thorne Bay on eastern Prince of Wales Island, approximately 40 air miles northwest of Ketchikan. According to the 2000 Census, Thorne Bay had a 2000 population of 557, with Alaska Natives comprising 16 percent of the total (U.S. Census Bureau 2001).

Petroglyphs and other archaeological remains indicate occupation and use of the area by Alaska Natives dating back at least 3,000 years. Post-contact development began in the early 1900s with construction of a saltery on the south shore of Thorne Bay (ADF&G 1994).

In 1960, a floating logging camp was built in Thorne Bay, and, in 1962, a shop, barge terminal, log sort yard, and camp were built to replace facilities at Hollis. Thorne Bay was incorporated as a second class city in 1982, making it one of Alaska's newest cities. Thorne Bay is accessible by road, water, or floatplane. Three air carriers serve the community with six to ten flights daily, and the Alaska Marine Highway system is accessed by the road system to Hollis (ADF&G 1994).

Thorne Bay's population decreased by 4 percent between 1990 and 2000. Population in Thorne Bay decreased further between 2000 and 2005, with an estimated net loss of 71 residents or 13 percent of the community's population in 2000. Total estimated population was 482 in Thorne Bay in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	443	377	581	557	486	482

Source: USDA Forest Service, 1997a; U.S. Census Bureau, 2001; Alaska DOL, 2007a

The Thorne Bay economy is primarily based on the timber industry and the U.S. Forest Service management of the National Forest. Logging operations in the area are generally seasonal (March to November) and include a major log transfer site for Prince of Wales Island. The 2006 mill survey conducted for the USDA Forest Service identified three active timber processors in Thorne Bay: Porter Lumber Company, Thuja Plicata Lumber Company, and Thorne Bay Wood Products. These mills had a combined installed production capacity of 25 MMBF and together processed approximately 1.2 MMBF in 2006 and employed about 8 people (Juneau Economic Development Council 2007). Northern Star Cedar Products, also located in Thorne Bay, was recently subdivided and sold as three separate operations, with each part now under new ownership.

Commercial fishing (22 residents hold permits), tourism, and government also provide employment (Alaska DCED 2002).

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. Approximately 15 percent of the labor force in Thorne Bay was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $45,625, compared to a regional median of $44,118 (Alaska DCED 2002).

Source: Alaska DCED 2002

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Thorne Bay is part of the North Prince of Wales community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record. Wood products employment in the North Prince of Wales community group declined by 186 jobs or 69 percent between 1990 and 1999. Wood products employment accounted for 83 jobs or 23 percent of total employment in this community group in 1999.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Thorne Bay in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-30. This area contains 1,000,251 acres of National Forest System land (among other land ownerships). Table 3.23-60 shows how the lands within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs presently account for 54 percent of the total acreage within the Thorne Bay community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 through 3. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 40 percent under Alternative 5 (No Action) to 61 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-60). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 62 percent and 78 percent under Alternatives 4 and 7, respectively, compared to 55 percent under Alternative 5.

Total suitable acres would range from 17 percent under Alternative 1 to 31 percent under Alternative 7, compared to 21 percent of the total community use area under Alternative 5 (No Action) and Alternative 6 (Proposed Action).

Economy

Thorne Bay is primarily a logging community and as such would be directly affected by the amount of logging opportunities on north Prince of Wales Island, as well as elsewhere on the Tongass. The mill survey conducted by the Forest Service in 2000 identified four sawmills operating in Thorne Bay. Three of these mills were also identified in the survey conducted for 2006 (Juneau Economic Development Council 2007). Approximately 6.5 MMBF was under contract in the Thorne Bay Ranger District in August 2006. This volume would not be affected under any of the alternatives. These data provide an indication of potential impacts, actual impacts would depend on the volume that is under contract when the decision is implemented and whether potentially affected existing sales were cancelled as part of the decision.

The 1997 Forest Plan EIS indicated that several small timber operators produce value-added products in Thorne Bay. These value added products include music wood, cabinets, and other products. They need relatively low volumes of timber, but of specific species and grades to meet their needs. All alternatives should meet these needs.

The lodges located near the community would not be affected under any of the alternatives.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 75 percent of the total edible pounds of subsistence resources harvested by Thorne Bay households (Kruse and Frazier 1988). Marine resources (fish and marine

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

invertebrates) accounted for 54 percent of per capita subsistence harvest in Thorne Bay in 1998.

The 1988 TRUCS study found that deer accounted for 20 percent of the total edible pounds of subsistence resources harvested by Thorne Bay (Kruse and Frazier 1988). Deer accounted for 27 percent of per capita subsistence harvest by Throne Bay residents in 1998 (ADF&G 2006).

Thorne Bay residents harvest deer almost entirely on Prince of Wales Island, which is included in GMU 2. Deer harvest and hunter effort in GMU 2 generally increased during 1997-2000 and subsequently declined during 2000-2004; however, no change has been noted in the average number of hunter-days required to harvest a deer (ADF&G 2005). As noted above, Thorne Bay's human population declined by an estimated 13 percent between 2000 and 2005, with an estimated 2005 population of 486.

Residents of Thorne Bay harvest the majority (79 percent) of their deer from two WAAs in north-central Prince of Wales Island (1319 and 1315). As shown in Table 3.23-61, the Thorne Bay portion represents about 56 percent and 42 percent of the total harvest and about 70 percent and 65 percent of the rural hunter harvest in these WAAs, respectively. About 28 percent of the combined harvest in these WAAs is by non-rural hunters, suggesting that there is a limited harvest buffer that could be restricted, if necessary, before restrictions are placed on rural harvests.

WAAs 1319 and 1315 occur in an area with substantial past harvest and, therefore, deer habitat capabilities are currently estimated to be below 1954 levels (Table 3.23-61). Under each of the alternatives, additional harvest would occur that would reduce habitat capabilities after 100+ years to 54-69 percent of 1954 levels in WAA 1319 and 41-50 percent in WAA 1315.

Table 3.23-61
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Thorne Bay Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability							
WAA	Thorne Bay Residents	All Rural Hunters	All Hunters	2005	Alt 1	Alt 2	Alt 3	Alt 4	Alt 5	Alt 6	Alt 7
1319	123	177	220	74	69	67	66	59	64	64	54
1315	115	175	270	55	50	49	47	44	47	47	41

*Calculated based on harvest where location is known.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide sufficient habitat capability over the long term for deer hunted by Thorne Bay residents. Projected deer harvest in the Thorne Bay community use area by all rural hunters and all hunters is estimated to exceed 10 percent habitat capability, the level that the analysis is assumed would provide a reasonably high level of hunter success for their effort, in the short and long term.

In summary, use of most subsistence resources by Thorne Bay residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives.

However, subsistence use of deer may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1. The risks of this occurring are greatest under Alternative 7 because of its general lack of Non-Development LUDs throughout most of Prince of Wales Island, and second highest under Alternative 4 because of its lower use of Non-Development LUDs than the other alternatives. Alternatives 1, 2, and 3 would have the lowest risk and Alternatives 5 and 6 would be intermediate. The risk of hunting restrictions would be reduced somewhat, through more intensive management (e.g., thinning) of the existing and future closed-canopy, young-growth forests in this area. Indirect effects associated with increased competition for deer within Thorne Bay's subsistence use areas could also occur under all alternatives due to displacement of hunters from other communities due to timber harvest activity. Additional road development under the alternatives would improve access but may increase competition with other non-local hunters. The level of road development is already relatively high in these WAAs. Existing open road densities are 0.6 and 1.5 miles per square mile and existing total road densities are 1.2 and 2.0 miles per square mile in WAAs 1319 and 1315, respectively (all ownerships combined). Long-term (100+ years) road development would vary by alternative and would result in estimated maximum total road densities of 1.3 and 2.7 miles per square mile in these two WAAs under Alternative 1, to 1.7 and 2.9 miles per square mile in these two WAAs under Alternative 7 (for all ownerships combined).

Whale Pass

Whale Pass is a dispersed unincorporated community located on the northeast coast of Prince of Wales Island. According to the 2000 Census, Whale Pass had a 2000 population of 58, with Alaska Natives comprising one percent of the total (U.S. Census Bureau 2001).

Whale Pass was originally established as a logging camp by Ketchikan Pulp Company in the early 1960s. According to local residents, a float camp housed loggers and their families in this location for almost 30 years. In 1982, the float camp was removed and many of the logging families left. Others moved to trailer pads on land at the head of the cove. That same year, Whale Pass became the site of a State land sale, which brought renewed population growth and the founding of a homeowners association. The community has been connected to the road system on Prince of Wales Island since 1981. A log transfer station remains on the southwest side of the bay (ADF&G, 1994).

The population of Whale Pass decreased by 17 residents between 1990 and 2000. Population has increased by an estimated 18 residents or 31 percent since 2000. Total estimated population was 61 in Whale Pass in 2006 (Alaska DOL 2007a).

Year	1980	1990	2000	2005	2006
Population	90	75	58	76	61

Source: USDA Forest Service, 1997a; U.S. Census Bureau, 2001; Alaska DOL, 2007a

Whale Pass is primarily dependent on the timber industry, with logging operations and the local school being the only employers in the area (Alaska DCED 2002).

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. These data are extrapolated from a sample of the city population. Since the sample size was small, the extrapolation may not be exact but should provide a general indication of the distribution of employment. The 2000 U.S. Census identified a potential work force of 37 residents and total employment of 14. While no adults in Whale Pass were identified as unemployed and looking for work in 2000, 62 percent were identified as unemployed and not looking for work. Median household income was $62,083, compared to a regional median of $44,118 (Alaska DCED 2002).

Source: Alaska DCED 2002

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Whale Pass is located in the Thorne Bay Ranger District and is part of the North Prince of Wales community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record. Wood products employment in the North Prince of Wales community group declined by 186 jobs or 69 percent between 1990 and 1999. Wood products employment accounted for 83 jobs or 23 percent of total employment in this community group in 1999.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Whale Pass in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-31. This area contains 1,000,251 acres of National Forest System land (among other land ownerships). Table 3.23-62 shows how the lands within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs presently account for 54 percent of the total acreage within the Whale Pass community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 through 3. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 40 percent under Alternative 5 (No Action) to 61 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-62). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 62 percent and 78 percent under Alternatives 4 and 7, respectively, compared to 54 percent under Alternative 5.

Figure 3.23-31
Whale Pass' Community Use Area

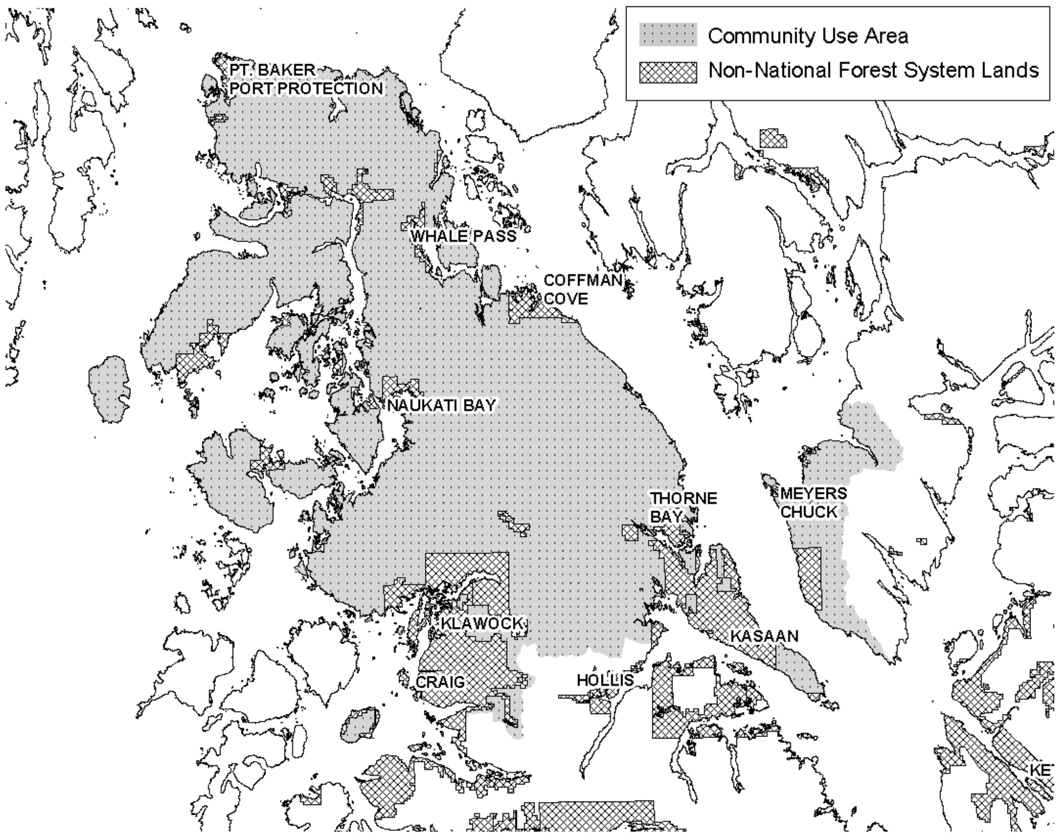

Table 3.23-62
LUD Groups in Whale Pass' Community Use Area by Alternative

	Alternative

Total	**1,000,248**	**1,000,249**	**1,000,251**	**1,000,252**	**1,000,251**	**1,000,249**	**1,000,249**

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

Total suitable acres would range from 17 percent under Alternative 1 to 31 percent under Alternative 7, compared to 21 percent of the total community use area under Alternative 5 (No Action) and Alternative 6 (Proposed Action).

Economy

Residents of Whale Pass could be potentially affected by changes in timber harvest, karst protection, recreation and tourism, and subsistence opportunities. Members of several speliological societies derive a portion of their income from cave and karst analysis and exploration in the vicinity. The Whale Pass Resort and a retail store are located in Whale Pass.

Approximately 6.5 MMBF was under contract in the Thorne Bay Ranger District in August 2006. This volume would not be affected under any of the alternatives. These data provide an indication of potential impacts, actual impacts would depend on the volume that is under contract when the decision is implemented and whether potentially affected existing sales were cancelled as part of the decision.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 60 percent of the total edible pounds of subsistence resources harvested by Whale Pass households (Kruse and Frazier 1988). Marine resources (fish and marine invertebrates) accounted for 65 percent of per capita subsistence harvest in Whale Pass in 1998.

The 1988 TRUCS study found that deer account for 27 percent of the total edible pounds of subsistence resources harvested by Whale Pass households (Kruse and Frazier, 1988). Deer accounted for 27 percent of per capita subsistence harvest by Whale Pass residents in 1998 (ADF&G 2006).

The majority of deer harvest by Whale Pass residents occurs on Prince of Wales Island, which is included in GMU 2. Deer harvest and hunter effort in GMU 2 generally increased during 1997-2000 and subsequently declined during 2000-2004; however, no change has been noted in the average number of hunter-days required to harvest a deer (ADF&G 2005). As noted above, the human population of Whale Pass increased by and estimated 31 percent from 2000 to 2005, with an estimated 2005 population of 76, which roughly matches the community’s 1990 population level.

Residents of Whale Pass harvest the majority (83 percent) of their deer from two WAAs in north Prince of Wales Island (1530 and 1529). As shown in Table 3.23-63, the Whale Pass portion represents about 12 percent and 2 percent of the total harvest and about 21 percent and 3 percent of the rural hunter harvest in these WAAs, respectively. About 46 percent of the combined harvest in these WAAs is by non-rural hunters, suggesting that there is a harvest buffer that could be restricted, if necessary, before restrictions are placed on rural harvests.

WAAs 1530 and 1529 occur in an area with substantial past harvest and, therefore, deer habitat capabilities are currently estimated to be below 1954 levels (Table 3.23-63). Under each of the alternatives, additional harvest would occur that would reduce habitat capabilities after 100+ years to 50-58 percent of 1954 levels in WAA 1530 and 50-63 percent in WAA 1529.

Table 3.23-63
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Whale Pass Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability							
WAA	Whale Pass Residents	All Rural Hunters	All Hunters	2005	Alt 1	Alt 2	Alt 3	Alt 4	Alt 5	Alt 6	Alt 7
1530	17	80	147	62	58	57	55	54	55	55	50
1529	4	122	226	73	63	61	60	56	59	59	50

*Calculated based on harvest where location is known.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide sufficient habitat capability over the long term for deer hunted by Whale Pass residents. Projected deer harvest in the Whale Pass community use area by all rural hunters and all hunters is estimated to exceed 10 percent habitat capability, the level that the analysis assumed would provide a reasonably high level of hunter success for their effort, in the short term and long term.

In summary, use of most subsistence resources by Whale Pass residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives. However, subsistence use of deer may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1. The risks of this occurring are greatest under Alternative 7 because of its general lack of Non-Development LUDs throughout most of Prince of Wales Island, and second highest under Alternative 4 because of its lower use of Non-Development LUDs than the other alternatives. Alternatives 1, 2, and 3 would have the lowest risk and Alternatives 5 and 6 would be intermediate. The risk of hunting restrictions would be reduced somewhat, through more intensive management (e.g., thinning) of the existing and future closed-canopy, young-growth forests in this area. Indirect effects associated with increased competition for deer within the Whale Pass subsistence use areas could also occur under all alternatives due to displacement of hunters from other communities due to timber harvest activity. Additional road development under the alternatives would improve access but may increase competition with other non-local hunters. The level of road development is already relatively high in these WAAs. Existing open road densities are 1.1 and 0.9 miles per square mile and existing total road densities are 1.7 and 1.5 miles per square mile in WAAs 1530 and 1529, respectively (all ownerships combined). Long-term (100+ years) road development would vary by alternative and would result in estimated maximum total road densities of 1.9 and 1.7 miles per square mile in these two WAAs under Alternative 1, to 2.0 miles per square mile in both WAAs under Alternative 7 (for all ownerships combined).

Wrangell

Wrangell is located on the north end of Wrangell Island, near the mouth of the Stikine River, an historic trade route to the Canadian interior. According to the 2000 Census, Wrangell had a 2000 population of 2,308, with Alaska Natives comprising 16 percent of the total (U.S. Census Bureau 2001).

Wrangell began as an important Tlingit site primarily because of its proximity to the Stikine River. Wrangell clans held a monopoly of trading rights along the Stikine. In 1811, the Russians began fur trading with area Tlingits and built a stockade named

Redoubt Saint Dionysius in 1834. In 1867, a military post named Fort Wrangell was established as part of the Alaska Territory. The community continued to grow because of its strategic location as a military fur trading center, and as an outfitter for gold prospectors between 1861 and the 1930s (ADF&G 1994; Alaska DCED 2006).

Wrangell is incorporated as a home rule municipality and has maintained its historic cultural diversity. The community has a local Fish and Game Advisory Committee. In a move to emphasize the importance of subsistence, the Wrangell Indian Reorganization Act Council has formed its own local Fish and Game Advisory Committee (ADF&G 1994).

The Silver Bay sawmill is located in Wrangell. According to the 2006 mill survey conducted for the USDA Forest Service, this mill, which has an installed production capacity of 65 MMBF, processed approximately 6 MMBF in 2006 and employed 30 people (Juneau Economic Development Council 2007).

Wrangell's population, which increased 22 percent between 1970 and 1990, decreased by 171 residents or 7 percent between 1990 and 2000. The population decreased by a further estimated 334 residents or 14 percent from 2000 to 2005. Total estimated population was 1,911 in Wrangell in 2006 (Alaska DOL 2007a).

Year	**1970**	**1980**	**1990**	**2000**	**2005**	**2006**
Population	2,029	2,184	2,479	2,308	1,974	1,911

Source: USDA Forest Service, 1997a; U.S. Census Bureau, 2001; Alaska DOL, 2007a

The Wrangell economy is primarily based on commercial fishing (250 residents hold permits), fish processing, and the timber industry. Estimated gross fishing earnings of local residents approached $5 million in 2000. A dive fishery, including for urchins, sea cucumbers, and geoducks, is developing. The Alaska Pulp Corp. sawmill, closed in 1994, was sold to Silver Bay Logging and reopened in April 1998. Wrangell also has a tourist business attracted by sportfishing in Stikine River and by a deep-water port for docking large and small cruise ships (Alaska DCED 2002; 2006).

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. Approximately 9 percent of the labor force in Wrangell was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $43,250, compared to a regional median of $44,118 (Alaska DCED 2002).

Employment by Industry	**Number**	**Percent of Total**

Total Employment	**1,079**	**100**

Source: Alaska DCED 2002

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Wrangell is part of the Wrangell City community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record.

Sawmill employment decreased by 62 percent in the Wrangell City community group between 1990 and 1999, a reduction from 162 to 62 jobs. The wood products sector accounted for 9 percent of total employment in the Wrangell City community group in 1999. The main employers in 1999 were the non-federal government and retail trade sectors, which accounted for 24 and 18 percent of total employment, respectively.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Wrangell in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-32. This area contains 819,240 acres of National Forest System land (among other land ownerships). Table 3.23-64 shows how the lands within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs presently account for about 36 percent of the total acreage within the Wrangell community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in the community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 and 2. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 20 percent under Alternative 5 (No Action) to 45 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-64). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 48 percent under both of these alternatives compared to 36 percent under Alternative 5.

Total suitable acres would range from 5 percent under Alternative 1 to 16 percent under Alternative 7, compared to 11 percent of the total community use area under Alternative 5 (No Action) and Alternative 6 (Proposed Action).

Economy

Commercial fishing, timber processing, recreation and tourism, and subsistence opportunities are particularly important to Wrangell. Wrangell is one of the stop-over points for visitors traveling to the Stikine River and the Stikine-LeConte Wilderness.

Commercial fisheries employment and recreation and tourism activities are not likely to be affected under any of the alternatives.

Approximately 26.2 MMBF of timber was under contract in the Wrangell Ranger District in August 2006. About 58 percent (15.2 MMBF) of this volume could be potentially affected under Alternative 1, which would maintain all Inventoried Roadless Areas on the Tongass in a natural condition and not permit timber harvest in these areas. None of the other alternatives would affect this volume. These data

Figure 3.23-32

provide an indication of potential impacts, actual impacts would depend on the volume that is under contract when the decision is implemented and whether potentially affected existing sales were cancelled as part of the decision.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 52 percent of the total edible pounds of subsistence resources harvested by Wrangell households (Kruse and Frazier 1988). Marine resources (fish and marine invertebrates) accounted for 84 percent of per capita subsistence harvest in Wrangell in 1987.

The 1988 study found that deer account for 21 percent of the total edible pounds of subsistence resources harvested by Wrangell households (Kruse and Frazier 1988). Deer accounted for a small amount of per capita subsistence harvest by Wrangell residents in 1987 (ADF&G 2006).

Wrangell residents mainly harvest deer on Wrangell and surrounding islands, with the majority of harvest occurring in GMU 3. Deer harvest in GMU 3 declined between 1998-2002 and increased between 2002-2004. The number of deer hunters declined between 2000-2002 and slightly increased between 2002-2004 (ADF&G 2005). As noted above, the human population of Wrangell decreased by an estimated 14 percent between 2000 and 2005. Wrangell had an estimated population of 1,974 in 2005.

Deer harvest by Wrangell residents is spread over many WAAs, but the majority (76 percent) of their deer are from five WAAs located on Wrangell and surrounding islands. Zarembo Island (WAA 1905) alone accounts for about half (51 percent) of Wrangell deer harvest. The Wrangell portion of the harvest in these five WAAs represents about 72 percent of the total harvest and about 80 percent of the rural hunter harvest (Table 3.23-65).

The majority of the WAAs used heavily by Wrangell residents are in areas with substantial past harvest and deer habitat capabilities are currently estimated to be considerably below 1954 levels (Table 3.23-65). Under each of the alternatives, additional harvest would further reduce habitat capabilities after 100+ years. Reductions would be smallest under Alternative 1 and highest under Alternative 7.

Table 3.23-65
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Wrangell Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability

1906	17	17	20	59	55	55	55	55	55	55	53

*Calculated based on harvest where location is known.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that the 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide sufficient habitat capability for deer hunted in the Wrangell community use area by Wrangell residents, all rural hunters, and all hunters in the short term. This is also estimated to be the case for Wrangell residents and all rural hunters in the long term. Projected deer harvest by all hunters is, however, estimated to exceed 10 percent habitat capability, the level that the analysis assumed would provide a reasonably high level of hunter success for their effort, in the long term.

In summary, use of most subsistence resources by Wrangell residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives. However, subsistence use of deer may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1. The risks of this occurring are greatest under Alternative 7, and second highest under Alternative 4. Alternatives 1, 2, and 3 would have the lowest risk and Alternatives 5 and 6 would be intermediate. The risk of hunting restrictions would be reduced somewhat, through more intensive management (e.g., thinning) of the existing and future closed-canopy, young-growth forests in this area. Indirect effects associated with increased competition for deer within Wrangell's subsistence use areas could also occur under all alternatives due to displacement of hunters from other communities due to timber harvest activity. Additional road development under the alternatives would improve access but may increase competition with other non-local hunters. The level of road development is already relatively high in most of these WAAs. Existing open road densities range from 0.3 to 1.1 miles per square mile and existing total road densities range from 0.3 to 1.7 miles per square mile in the five most important WAAs for Wrangell deer harvest). Long-term (100+ years) road development would vary by alternative and would result in estimated maximum total road densities ranging from 0.4 to 1.9 miles per square mile in these WAAs under Alternative 1, to 1.1 to 2.0 miles per square mile under Alternative 7 (for all ownerships combined).

Yakutat

Yakutat is located in the lowlands along the northern Gulf of Alaska, 212 miles northwest of Juneau at the mouth of Yakutat Bay. According to the 2000 Census, Yakutat had a 2000 population of 680, with Alaska Natives comprising 47 percent of the total (U.S. Census Bureau 2001).

Yakutat, which means "the place where the canoes rest," has a diverse cultural history. The original settlers, believed to have been Eyak people from the Copper River area, were later conquered by the Tlingits. Intensive contact with European explorers came in the late 1700s when a Russian fur trading company moved into the Yakutat area. By the mid-1800s, foreign traders were well established along the coast. The contemporary town grew up around "the old village," which was established in 1889 by missionaries (ADF&G 1994).

Incorporated as a first-class city in 1948, Yakutat is governed by a mayor and a city council. Yakutat Borough, incorporated in 1992, expanded the original city boundaries to include a large section of the Gulf Coast north of Cape Fairweather. Yakutat has a local Fish and Game Advisory Committee. Yakutat is accessible by jet service from Juneau and Anchorage. Wrangell-Saint Elias National Park, Russell Fiords Wilderness, and Glacier Bay National Park are located northwest, northeast, and southeast of Yakutat, respectively.

The population of Yakutat, which almost tripled between 1970 and 1990, increased by 27 percent between 1990 and 2000. Population in Yakutat has, however, decreased since 2000, with an estimated net loss of 62 residents or 9 percent of the

2000 population. Total estimated population was 609 in Yakutat in 2006 (Alaska DOL 2007a).

Year	1970	1980	1990	2000	2005	2006
Population	190	449	534	680	618	609

Source: USDA Forest Service, 1997a; U.S. Census Bureau, 2001; Alaska DOL, 2007a

The Yakutat economy is primarily dependent on fishing, fish processing, and government. A total of 162 residents hold commercial fishing permits. Fishing opportunities in the area, both freshwater in the Situk River and saltwater, are considered world class, and 25 percent of the local residents have commercial fishing licenses. North Pacific Processors is the major private employer (Alaska DCED 2002; 2006).

Employment by industry data compiled by the Alaska DCED from the 2000 Census are summarized in the table below. Approximately 8 percent of the labor force in Yakutat was identified as unemployed and seeking work in 2000, compared to 7 percent for Southeast Alaska as a whole. Median household income was $46,786, compared to a regional median of $44,118 (Alaska DCED 2002).

Please refer to the 1997 Forest Plan EIS for further details on the history, economy, and subsistence use of this community.

Yakutat is part of the Yakutat community group (see Table 3.23-6). Detailed employment data are available for this community group by economic sector for 1990, 1995, and 2000 in the planning record.

Employment by Industry	Number	Percent of Total
Agriculture, Forestry, Fishing & Hunting, Mining	136	31
Construction	32	7
Manufacturing	25	6
Wholesale Trade	0	0
Retail Trade	21	5
Transportation, Warehousing & Utilities	64	15
Information	5	1
Finance, Insurance, Real Estate, Rental & Leasing	9	2
Professional, Scientific, Management, Administrative & Waste Mgmt	0	0
Education, Health & Social Services	62	14
Arts, Entertainment, Recreation, Accommodation & Food Services	43	10
Other Services (Except Public Admin)	13	3
Public Administration	30	7
Total Employment	**440**	**100**

Source: Alaska DCED 2002

The services and non-federal government sectors were the main employers in the Yakutat community group in 1999, accounting for 24 and 21 percent of total employment, respectively. Seafood processing accounted for 17 percent and recreation and tourism-related activities (lodging, restaurants, and recreation services) accounted for 19 percent of total employment. Wood products (logging) employment decreased by 65 percent between 1990 and 1999 and accounted for just 3 percent of total employment in 1999.

Potential Effects

Community Use Area

The general area commonly used or related to by many of the residents of Yakutat in their local day-to-day work, recreational, and subsistence activities is shown on Figure 3.23-33. This area contains 250,271 acres of National Forest System land (among other land ownerships). Table 3.23-66 shows how the lands within this community use area would be distributed among the LUD groups by alternative. The LUD groups are explained in the introduction to Chapter 3.

Development LUDs presently account for just 15 percent of the acreage in the Yakutat community use area. Alternatives 5 and 6 would not have a significant effect on existing LUD allocations in this community use area because the acreage by LUD group would remain the same as under the existing Forest Plan. The acreage allocated to Wilderness/National Monument LUDs would remain constant under all alternatives. The amount of acreage allocated to Mostly Natural LUDs would increase under Alternatives 1 and 2. The largest increase would occur under Alternative 1, with the acreage allocated to Mostly Natural LUDs increasing from 47 percent under Alternative 5 (No Action) to 62 percent under Alternative 1, with a commensurate reduction in development LUDs (Table 3.23-66). Alternatives 4 and 7 would increase the acreage in development LUDs. Development LUDs would account for 18 percent of the Yakutat Community Use Area under both of these alternatives compared to 15 percent under Alternative 5.

Total suitable acres would range from no acreage under Alternative 1 to 8 percent under Alternatives 4 and 7, compared to 7 percent of the total community use area under Alternative 5 (No Action).

Economy

Commercial fishing and subsistence are important to Yakutat. Oil exploration may begin again in the Pacific Ocean close to Yakutat. The Yakutat Forelands are some of the community's most important subsistence use areas. Commercial fishing is not expected to be affected under any of the alternatives.

Subsistence

No significant effect on salmon, other finfish, or invertebrate habitat capability is expected from implementation of any alternative. These resources account for 82 percent of the total edible pounds of subsistence resources harvested by Yakutat households (Kruse and Frazier 1988). Marine resources (fish and marine invertebrates) accounted for 74 percent of per capita subsistence harvest in Yakutat in 2000.

Moose are more important than deer as a subsistence meat source for Yakutat residents. Moose availability would not be significantly affected under any of the alternatives.

The 1988 TRUCS study found that deer account for only a small fraction of the total edible pounds of subsistence resources harvested by Yakutat households (Kruse and Frazier, 1988). Deer accounted for 1 percent of per capita subsistence harvest by Yakutat residents in 2000 (ADF&G 2006).

Figure 3.23-33
Yakutat's Community Use Area

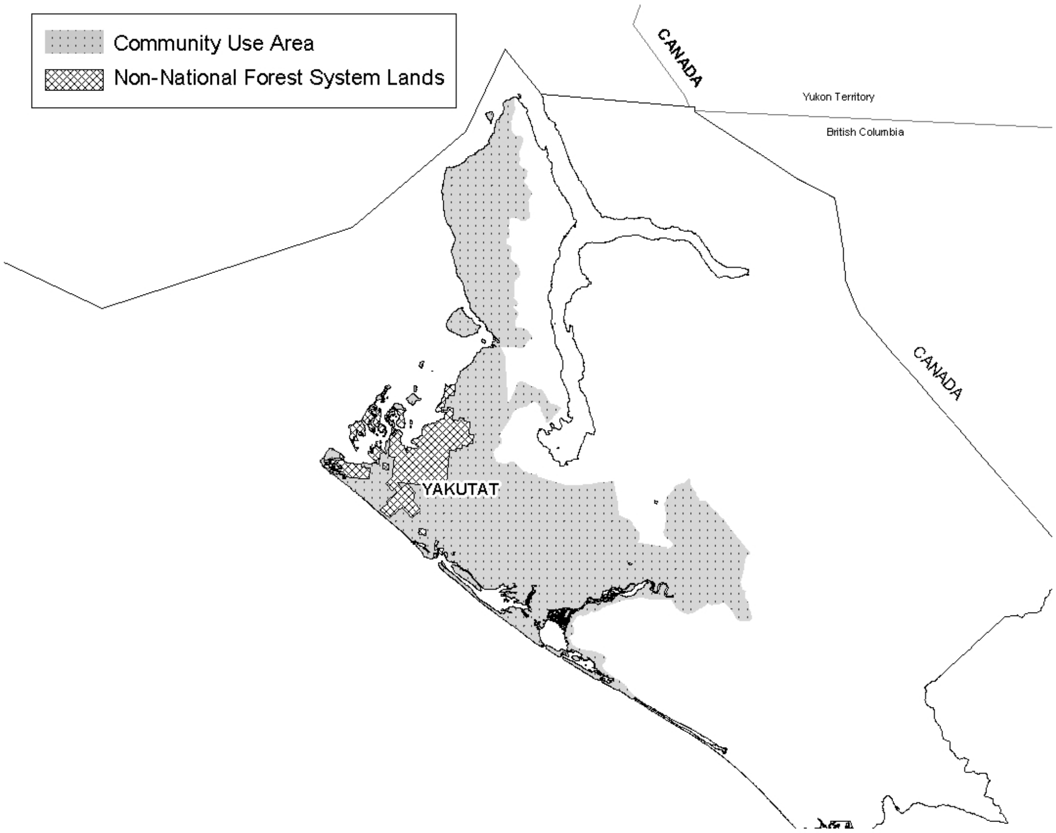

Table 3.23-66
LUD Groups in Yakutat's Community Use Area by Alternative

	Alternative						
	1	2	3	4	5	6	7

[1] See the accompanying large LUD map for the distribution of existing LUDs and the Alternative Maps for the distribution of LUDs by alternative.

Yakutat residents harvested very few deer from 1996-2002, harvesting an annual average of more than one deer in just two WAAs over this period (Table 3.23-67). One of these WAAs is located in GMU 4; the other is located in GMU 5A. Deer harvest in GMU 4 is considered very high relative to other areas of Southeast Alaska, which is indicative of relatively high deer populations (ADF&G 2005). Over 1997-2004, there has been no significant trend in the number of deer harvested or in the number of hunters (ADF&G 2005). The human population of Yakutat declined by an estimated 9 percent between 2000 and 2005, with an estimated 2005 population of 618 residents.

Yakutat residents take the majority (78 percent) of their deer from two WAAs (Table 3.23-67). These numbers are, however, somewhat misleading due to the overall low deer harvest levels. In addition, deer harvest only occurred in WAA 4252, which is some distance from Yakutat near Hoonah, during one year.

Table 3.23-67
Deer Harvest (1996 to 2002) and Deer Habitat Capability on NFS Lands in 2005 and After 100+ Years of Full Implementation under Each Alternative, Expressed as a Percent of 1954 Habitat Capability, for the WAAs where Yakutat Residents Obtain Approximately 75% of their Average Annual Deer Harvest*

	Average Deer Harvest from 1996 to 2002			Deer Habitat Capability in 2005 and after 100+ Years of Full Implementation Under Each Alternative, Expressed as a Percent of the 1954 Habitat Capability							
WAA	Yakutat Residents	All Rural Hunters	All Hunters	2005	Alt 1	Alt 2	Alt 3	Alt 4	Alt 5	Alt 6	Alt 7
4252	4	75	99	92	92	78	78	70	77	76	69
4504	3	3	4	100	100	100	100	100	100	100	100
3835	1	4	218	100	100	100	100	100	100	100	100

*Calculated based on harvest where location is known.

The Deer Availability and Anticipated Demand analysis completed for the 1997 Forest Plan EIS determined that the 1997 Alternatives 2, 6, and 11, which are similar to the four highest harvest alternatives in this EIS, should be able to provide sufficient habitat capability for deer hunted in the Yakutat community use area by Yakutat residents, all rural hunters, and all hunters in the short term. This is also estimated to be the case for Yakutat residents and all rural hunters in the long term. Projected deer harvest by all hunters is, however, estimated to exceed 10 percent habitat capability, the level that the analysis assumed would provide a reasonably high level of hunter success for their effort, in the long term.

In summary, use of most subsistence resources by Yakutat residents (fish and marine invertebrates) is not expected to be affected by any of the alternatives. However, subsistence use of deer may be affected to the point that some restriction in hunting might be necessary over the long term, even under Alternative 1. With the exception of WAA 4252, the highest use areas for Yakutat households are within Wilderness and LUD II designations that will not change by alternative.

Environmental Justice

Executive Order 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations, requires each federal agency to make the achievement of environmental justice part of its mission by identifying and addressing disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority and low-income populations. The Order further stipulates that the agencies conduct their programs and activities in a manner that does not have the effect of excluding persons from participating in, denying persons the benefits of, or subjecting persons to discrimination under such programs, policies, and activities because of their race, color, or national origin.

Race and ethnicity are shown by borough in Table 3.23-68. These data show that 68 percent of the population of Southeast Alaska identified as White in the 2000 census. American Indian and Alaska Native was the largest minority group, accounting for 17 percent of the total Southeast Alaska population. Table 3.23-68 indicates that there are relatively large proportions of Alaska Natives in the Yakutat Borough and Prince of Wales-Outer Ketchikan and Skagway-Hoonah-Angoon Census Areas. The populations of Haines and Juneau, in contrast, have relatively low proportions of Alaska Natives, below the Southeast Alaska average of 17 percent.

Alaska Native populations are identified as a percentage of total population by community in Table 3.23-8. This information is presented graphically in Figure 3.17-1 (in the *Subsistence* section). These data indicate that 13 of Southeast Alaska's 32 communities have Alaska Native populations that comprise a larger share of total population than the regional average (17 percent). Alaska natives comprised a particularly large share of total population in Angoon (82 percent), Hoonah (61 percent), Hydaburg (85 percent), Kake (67 percent), Klawock (51 percent), Metlakatla (82 percent), and Saxman (66 percent), all considered traditional Native communities.

Table 3.23-68
Race/Ethnicity by Borough/Census Area, 2000

	2000 Population	Percent White	Percent American Indian and Alaska Native	Percent Two or More Races	Percent Other[1]	Percent Hispanic or Latino[2]

Alaska	626,932	69	16	5	10	4

[1] The "Other" category presented here includes respondents identifying as Black or African American, Asian, Native Hawaiian and Other Pacific Islander, and Other. These categories have been combined for ease of presentation and because they comprise small percentages of local populations.
[2] "Hispanic" can be of any race.
Source: U.S. Census Bureau, 2001.

The percent of households below the poverty line and the median household income in 2000 are also identified by community in Table 3.23-8. The percent of households below the poverty line in Alaska as a whole was 7 percent in 2000. Median household income was approximately $51,571. The U.S. Census identified 14 communities in Southeast Alaska with a larger percent of households below the poverty line than the state average. These communities include Klawock, Hoonah, Edna Bay, Hydaburg, Port Alexander, and Angoon, as well as Hyder and Port

Protection. Median household incomes ranged from $36,048 in Haines Borough to $49,924 in the City and Borough of Juneau (U.S. Census Bureau 2001). All but four of the communities identified in Table 3.23-8 had median household incomes below the state average. Communities with median household income below the regional average included Port Protection, Hyder, Point Baker, Edna Bay, Angoon, and Hydaburg.

The potential effects of the alternatives on the economic and social environment of Southeast Alaska are discussed in the *Economic and Social Environment* section of this document. The principal regional effects would be those associated with changes in the timber industry and recreation and tourism. There could also be potential effects upon subsistence use and heritage resources that have particular significance for Alaska Native populations.

The effects of the alternatives on communities are discussed by community in the preceding part of this section. These community assessments include a discussion of potential timber harvesting within each community's use area and the potential effects to the subsistence resources and the land base used by each community.

Wood products employment is projected to be higher than current levels under all of the alternatives, except Alternative 1. Projected increases for the other alternatives ranging from 1.8 times the 2005 harvest level under Alternative 2 to 3.9 times under Alternative 7. The slight increases in projected employment under Alternative 2 when compared to 2005 harvest levels is still a decrease when compared to projected employment levels under Alternative 5 (No Action). Further, it could be argued that the alternatives that do not emphasize timber production represent a possible foregone opportunity for increased employment in the wood products sector. Even viewed in terms of a comparison of alternative projections, relative reductions in employment would be unlikely to have a disproportionately high effect on low-income and minority communities or groups. Relative reductions in sawmill employment would be concentrated in Ketchikan, Wrangell, and Craig. Reductions in logging employment would likely be distributed throughout Southeast Alaska, depending upon the alternative.

The mix of available recreation opportunities would vary by alternative based on the allocation of the Forest to different LUD groups. However, viewed in terms of projected recreation and tourism employment over the next decade, there would be very little difference between the alternatives. Recreation and tourism-related economic impacts are not expected to disproportionately affect minority or low-income populations.

Subsistence issues are discussed for the region as a whole in the *Subsistence* section and for each of Southeast Alaska's 32 communities in the preceding part of this section. The deer analysis presented in the 1997 Tongass Forest Plan Final EIS indicated that deer habitat capabilities in several portions of the Tongass may not be adequate to sustain the current levels of deer harvests, which may result in restrictions on subsistence use at some point in the future.

The potential effects of the alternatives upon heritage resources are expected to be the same or lower than under the current Forest Plan. Because of the protection offered by Forest-wide standards and guidelines, effects on heritage resources are expected to be low under all the alternatives.

CHAPTER 4
LIST OF PREPARERS

List of Preparers

Provided below are brief biosketches of the preparers from Tetra Tech and the primary reviewers and contributors from the Forest Service. Other Forest Service, Tetra Tech, and other agency staff, who contributed to various sections through an extensive internal review process, or in other ways, are also listed.

Lee Kramer, Forest Service Project Manager

Education

B.S., Forest Management, Auburn University, 1979

A.A., Degree from Eastern Wyoming College, 1975

Experience

Thirty years of Forest Service experience, including various Ranger District staff positions in Alabama, Virginia, Oklahoma, and New Mexico.

Forest Planning or Forest Staff positions in Colorado, Wyoming, and Montana.

Larry Lunde, Tongass Planning Staff Officer – Forest Service

Education

B.S., Forest Management, Washington State University, 1973

Experience

Twenty-eight years of Forest Service experience.

Tongass National Forest, Environmental Coordinator and Planner.

Previous experience in forest and multiple-use management positions as District Resource Staff and District Ranger, including Nez Perce National Forest in Idaho, Eldorado National Forest in California, Gifford Pinchot National Forest in Washington, and Mount Hood and Fremont National Forests in Oregon.

Patricia O'Connor – Tongass Wildlife and Subsistence Staff Officer

Education

M.S., Natural Resource Management, Humboldt State University, 1988

B.S., Biology, Cornell University, 1983

Experience

Nineteen years of Forest Service experience, including several years as a staff wildlife biologist on the Mt. Hood National Forest in Oregon and on the Lolo National Forest in Montana. Five years as the Yukatat District Ranger on the Tongass National Forest.

Randal Fairbanks, Interdisciplinary Team Leader, Project Manager – TtEC

Education

M.S., Forest Resources, University of Washington, 1979

B.S., Wildlife Science, University of Washington, 1972

Experience

Thirty-three years of experience in design, conduct, and management of ecological and forest inventory and research, impact assessments, and mitigation plans.

Project manager or interdisciplinary team leader for 11 major forest management-related EIS/EA efforts.

Major contributor to dozens of other EISs, EAs, and Environmental Reports.

Joe Iozzi, Silviculturist/Forester, Asst. Project Manager – TtEC

Education

Silviculture Institute, University of Washington, 1984 to 1985

B.S., Forest Management, Rutgers University, 1977

Experience

Twenty-seven years of experience in silviculture and natural resource management, primarily on Forest Service and NEPA projects.

Thirteen years as a certified silviculturist for the Forest Service.

Nine years of experience working on timber sale and transportation management projects on the Tongass National Forest, project manager for the Forest-wide roads analysis and several NEPA projects.

Matt Dadswell, Senior Social Scientist/Economist – TtEC

Education

Ph.D., Candidate, Geography, University of Washington

M.A., Geography, University of Cincinnati, 1990

B.A., Economics and Geography, Portsmouth Polytechnic, 1988

Experience

Fifteen years of experience conducting economic, social, and environmental regulatory analysis on a variety of natural resource projects, including Forest Service and NEPA projects.

Ten years of experience working on Forest Service projects, including projects on the Tongass National Forest.

John Knutzen, Senior Fisheries Biologist/Aquatic Ecologist – TtEC

Education

M.S., Fisheries, University of Washington, 1977

B.A., Biology, Western Washington State College, 1972

Experience

Twenty-nine years of experience evaluating developmental activity impacts to lakes, rivers, and stream water quality and aquatic resources in the Pacific Northwest, with emphasis on salmonids.

Experience working on more than 60 projects in the Pacific Northwest, including assessing effects of federal actions on endangered fish species.

Provided scientific evaluation on more than 25 NEPA documents, including Forest Service EISs for the Tongass National Forest.

Steve Negri, Wildlife Biologist – TtEC

Education

M.S., Wildlife Ecology, Michigan State University, 1995

B.S., Business Finance, University of Missouri, 1985

Experience

Thirteen years of experience as a wildlife biologist, including work on three EISs for the Tongass National Forest and more than a dozen Forest Service-related projects.

Experience working on approximately 15 EISs and other NEPA documents in the Pacific Northwest and Alaska.

Previous experience includes working 5 years as threatened and endangered species biologist for the Washington Department of Fish and Wildlife.

Brita Woeck, Wildlife Biologist – TtEC

Education

M.S., Wildlife Ecology and Management, University of Missouri, Columbia, 2003

BS, Wildlife Science, University of Washington, 1999

Experience

Seven years of experience conducting all phases of ecological research.

Experience includes ecological study development and coordination, data collection and analysis, results interpretation and presentation, and NEPA analysis.

Work experience focuses on population dynamics, resource selection and space use patterns, and community ecology; with responsibility for vegetation and wildlife population surveys, radiotelemetry, and wildlife capture and immobilization.

Mary Jo Russell, GIS Analyst – TtEC

Education

B.S., Computer Information Systems, Menlo College

Experience

Fourteen years of experience as a GIS analyst specializing in creating complex riparian models, surface models, habitat models, perspective scene analysis, aerial photo interpretation of logging units, preparation of field maps, and final production of maps for numerous timber sale EISs.

Experience includes serving as lead GIS analyst on more than a dozen Forest Service projects, including four EIS projects specific to Southeast Alaska and the Tongass National Forest.

Mary Clare Schroeder, Wetland Scientist /Botanist – TtEC

Education

B.A., Botany, University of Washington, 2000

MBA, University of Chicago, 1993

Experience

Six years of experience working on EIS and NEPA documents.

Field experience performing wetland delineation; wetland mitigation; planning and monitoring; and national, state, and local project permitting.

Experience conducting wetland and plant surveys on the Tongass National Forest.

Stephanie Phippen, PG, Geoscientist – TtEC

Education

M.S., Geology/Watershed Science, Colorado State University, 2000

B.A., Geology, Carleton College, 1996

Professional Geologist, UT, Number 5557302-2250

Experience

Seven years of experience in siting, environmental assessment of impacts to watersheds and water resources.

Field of expertise is geomorphology (fluvial, colluvial, and glacial), with supporting strengths in hydrology (surface and groundwater), soil science, and statistics.

Experience completing analyses of water quality, road networks, geomorphology, soils, hydrology, geology, and cumulative effects for EIS, EA, landscape and watershed assessment, geologic risk assessment, and geomorphic mapping projects. Published original research that quantifies the impacts of roads and other forms of land management on stream-channel equilibrium, sediment movement, and watershed stability.

Dave Cox, Hydrologist/Minerals Specialist – TtEC

Education

B.S., Geology, Western Washington University, 2000

Experience

Six years of experience in hydrology, geomorphology, and natural resource management, primarily on Forest Service and NEPA projects.

Field of expertise is hydrology, geomorphology, and regulatory compliance with supporting strengths in soil science.

Previous experience working on three National Forests, including four years on the Tongass National Forest as project manager, hydrologist, and minerals administrator for projects including mine development, hydropower, transportation, and recreation.

Susan Corser, Landscape Architect/Recreation Planner – Ernst Corser Associates

Education

M.U.P., Urban Planning, University of Washington, 1989

M.A., Landscape Design, Conway School of Landscape Design, 1983

B.A., Geography and Environmental Studies, Macalester College, 1977

Experience

Twenty-one years of experience conducting visual analyses, recreation demand studies, urban planning, and public meeting facilitation. Conducted visual, recreation, and land use impact analyses for hydropower, mine, landfill, ski area, and water supply projects.

Ten years of experience working on environmental analyses on Forest Service or BLM lands, including two years experience working on NEPA projects within the Tongass National Forest.

Marcy Rand, Public Involvement Coordinator – TtEC

Education

B.A., Journalism and Mass Communications, Washington and Lee University, 1992

Experience

Thirteen years of writing/editing/public involvement experience.

Extensive writing/editing/public involvement experience with NEPA and Forest Service documents, including 10 EISs/EAs.

Experience includes developing, writing, and producing factsheets, brochures, newsletters, news releases and advertisements; public outreach plan development and implementation; scoping and public comment coordination; and public meeting assistance.

Maggie Huffer, Technical Editor/Public Involvement Coordinator – TtEC

Education

B.A., Journalism/Public Relations, Western Washington University, 2000

Experience

Seven years of experience writing, editing, and coordinating numerous environmental reports, including multi-volume EISs and other NEPA documents.

Experience working on four Forest Service EISs specific to Southeast Alaska and the Tongass National Forest.

T. Weber Greiser, Heritage Resource Specialist/Archaeologist

Education

M.A., Anthropology, University of New Mexico, 1972

B.A., Anthropology, University of New Mexico, 1969

Experience

Twenty-seven years of experience as Project Manager and/or Principal Investigator on heritage resource projects in Alaska and throughout the Western U.S. Experience includes prehistoric and historic archaeological predictive modeling; heritage resource surveys, testing projects, and excavations; laboratory analysis of artifacts and faunal remains; and ethnographic investigations and oral interviews of native inhabitants regarding land use, water use, and sacred lands.

Heritage resource Principal Investigator for background research, cultural resource survey, preparation of specialist report, and/or preparation of EA or EIS cultural resource sections for nine projects since 1993 on the Tongass.

Eric Henderson, SPECTRUM Model Analyst – USDS Forest Service, Region 9

Education

M.S., Forest Management (2003), University of Minnesota

B.B.A., Business Administration (2000), University of Iowa

Experience

Four years of experience as Forest Service Analyst/Planner, specializing in landscape planning models, growth and yield models, historic vegetation analysis, and computer programming languages.

Introduction

This Environmental Impact Statement (EIS) responds to the August 2005 U.S. Ninth Circuit Court Decision that found inadequacies primarily relating to the National Environmental Policy Act (NEPA) process for the 1997 Land and Resource Management Plan (Forest Plan or Plan). The Court directed the Forest Service to prepare an EIS that evaluates and considers timber demand, the range of alternatives related to the timber demand, and the cumulative analysis related to activities on non-National Forest System (NFS) lands. This is discussed further in Chapter 1 of the EIS. This EIS responds to the Court and the 5-Year Review by analyzing six alternatives for amending the Plan in addition to the No-Action alternative. Appendix A of the 1997 Final EIS discusses the issue identification process used in the Tongass National Forest planning process.

Identification of issues helps define or predict what resources or uses could be most affected by the planning alternatives under consideration. These issues are then used as a basis to formulate alternatives or to measure differences between alternatives. The following sections describe the process used to identify the issues for this EIS and the key issues identified.

The scope of this EIS was initially determined by the Court in its 2005 ruling, and by the 5-Year Plan Review (completed in January 2005) that indicated the need to amend the current Tongass Forest Plan. Additional information was considered to help clearly define the issues and for use in the development and analysis of alternatives. For this EIS, comments and information from a wide variety of public inputs that were related to amending the Forest Plan were considered. This information included:

- Public comments generated during the 1997 Tongass Forest Plan Revision process;
- Tongass Forest Plan Revision appeals;
- Public input specific to the Tongass National Forest on the Forest Service's 2001 National Roadless Area Conservation Rule;
- Public comments generated relative to the 2003 Supplemental EIS, Roadless Area Evaluation for Wilderness Recommendations;
- Public input expressed during project-level NEPA analyses over approximately the past 10 years; and
- Public input received in response to the Notice of Intent and the Web site for this EIS.

This record of public input on the management of the Tongass covers a period of almost 2 decades.. Of special note are the extensive public meetings held in Southeast Alaska for the 1997 Forest Plan Revision, the 2001 National Roadless Area Conservation Rule, and the 2003 Supplemental EIS.

Past Planning Efforts

Tongass Forest Plan Revision

Appendix L of the 1997 Final EIS presents summaries of all substantive comments received during the three public comment periods for the Tongass Forest Plan Revision, as well as presents Forest Service responses to these comment summaries. All public comment periods held during the Tongass Forest Plan Revision were announced in the Federal Register, by news release, in local newspapers, and through newsletters. Informational meetings and open houses, followed by hearings, were held in most Southeast Alaska communities during each comment period. More than 3,000 individuals, organizations, interest groups, and agencies provided written or oral input on the 1990 Draft EIS, and more than 7,000 and 21,000 responses were received on the 1991 Supplement and the 1996 Revised Supplement, respectively.

Comments summarized in Appendix L were identified by location and issue and entered into a database that had more than 850 entries. Information developed through this review was used to help identify public interest in specific roadless areas, as well as in the issue identification process.

Tongass Forest Plan Revision Appeals

A total of 23 appeals were received on the 1997 Tongass Land Management Plan Revision Record of Decision (ROD). These appeals were reviewed and comments were summarized by location and issue and entered into a database. Information developed through this review was used to help identify public interest in specific roadless areas, as well as in the issue identification process.

National Roadless Area Conservation Rule

More than 1.1 million separate pieces of public input were received on the National Roadless Area Conservation Rule Draft EIS. The results of the Forest Service's content analysis of these comments are presented in Volume 3 of the Roadless Area Conservation Final EIS along with the Forest Service's responses to the identified comment summaries (USDA Forest Service 2000). A portion of these comments specifically pertained to the Tongass. Some of these comments were in support of, and some were against, roadless area conservation on the Tongass. Some stated that roadless areas were important for wildlife and endangered and threatened species, some were concerned about effects on the regional economy, recreation, and subsistence (some indicated that limiting road construction would limit access for subsistence, while others stated that there are already sufficient roads on the Tongass to meet subsistence needs).

Project-Level EIS Analyses

Public input related to timber management, recreation, roadless areas, and other issues that has been expressed during project-level EIS analyses over approximately the past 10 years was considered. This included many recent project-level EISs and EAs completed since 1997, as well as several landscape-level plans. Many of the comments that addressed timber demand, economics, wildlife, subsistence, scenery, tourism, and roadless area issues were made in response to proposals to harvest timber and to build roads.

National Forest Transportation Rule and Policy

Public input on the National Forest Transportation Rule and Policy that pertained specifically to the Tongass was also reviewed as part of this issue identification process.

Supplemental EIS, Roadless Area Evaluation for Wilderness Recommendations

Public input on the Supplemental EIS, Roadless Area Evaluation for Wilderness Recommendations was also reviewed as part of this issue identification process. Approximately 177,000 separate pieces of input were received during the public comment period. Eighteen public hearings were held, 16 in Southeast Alaska, one in Anchorage, and one electronic public hearing (via the internet). Comments were received from all 50 states and at least 11 foreign countries. Comments generally focused on how much roadless area to retain and how this would effect recreation, tourism, timber, wildlife, subsistence, and the local economy. Comment summaries and Forest Service responses are presented in Volume IV of the Final Supplemental EIS, along with letters from agencies, elected officials, and tribal governments.

Public Issues

Identification of issues helps define or predict the resources or uses that could be most affected by the management of NFS lands. These issues are then used as a basis to formulate alternatives or to measure differences between alternatives.

Ten public issues were originally identified in 1988 for the Forest Plan Revision. These original issues included scenic quality, recreation, fish habitat, wildlife habitat, subsistence, timber harvest, roads, minerals, roadless areas, and local economy. The 1991 Forest Plan Revision Supplemental Draft EIS (SDEIS) added an additional concern, identifying and considering rivers for recommendation as Wild, Scenic, and Recreational rivers.

After the release of the 1991 SDEIS, considerable new information pertaining to the Tongass Forest Plan Revision became available. Out of this information emerged five additional issues, determined by the Regional Forester to need more study and evaluation before a final revised Forest Plan could be adopted. Some of these issues were aspects or extensions of the ten public issues previously considered; others were new as issues or had not been considered as issues in themselves. The five issues were wildlife viability, fish habitat, karst and caves, alternatives to clearcutting, and socioeconomic considerations. These issues were assessed in the 1996 Revised SDEIS and the 1997 Tongass Forest Plan Revision Final EIS.

The 2003 Supplemental EIS reviewed and evaluated roadless areas and analyzed alternative groupings of roadless areas for wilderness recommendations. Two broad issue categories, referred to as key issues, were identified as the major issues driving the alternatives and the analysis. They included 1) the long-term protection of roadless areas and associated values, and 2) the social and economic well-being of the communities of Southeast Alaska.

Public Input for this EIS

In addition to the above, extensive public involvement has occurred during the development of this EIS. All public input received has been reviewed and is maintained in the planning record. Comments and responses on the Draft EIS are also included in Appendix H. Public involvement activities have included the following items.

- The Notice of Intent was published in the Federal Register in March 2006.
- A Forest Plan Adjustment Web site was developed in January 2006 and has been maintained to inform and engage the public since then. It is updated as new information is developed or published and provides a mechanism for public input. Several hundred comments and questions were received through the Web site or via emails associated with the Web site in the first few months of operation.
- A Weblog regarding the Forest Plan adjustment effort was established in July 2006 and was continually maintained as another method of public communication.
- In response to the above items, a number of letters were received containing comments regarding the issues and alternatives. These included letters from environmental organizations, the timber industry, Southeast Alaska community organizations, and a number of individuals from Southeast Alaska and across the nation.
- Government-to-government consultation has been conducted throughout the process, and is ongoing, with federally recognized Tribes.
- A number of group-specific meetings have also occurred with various organizations (including Alaska Native groups).
- A variety of news releases were issued relative to the Forest Plan adjustment throughout the process.

- A series of ongoing meetings, hosted by the National Forest Foundation and The Nature Conservancy, known as the Tongass Futures Roundtable, have resulted in considerable discussion of Tongass management issues among a broad spectrum of individuals and groups interested in the future of Southeast Alaska since May 2006.
- The input received prior to issuance of the Draft EIS was reviewed and a summary of this synthesis is presented as Appendix A (Issue Identification) to the Final EIS.
- A Draft EIS and Proposed Forest Plan were released on January 12, 2007. This began a 90-day comment period, which was later extended to 108 days. The comment period closed on April 30, 2007.
- During the comment period, open houses and public hearings were held in 24 Alaska communities. In addition to comments on the Draft EIS, the hearings provided opportunity to hear concerns related to subsistence and Alaska Native issues.
- On March 22, 2007, an open house and public hearing was held on the internet, to solicit public comment in an open forum from individuals living anywhere in the world.
- Over 84,000 comment documents were received, including individual letters, form letters, emails, hearing testimony, and comments submitted directly via the Forest Plan Adjustment Web site. Slightly more than 2,000 of these were classified as individual comment documents and the others were classified as form letters and emails. The individual comment documents were subdivided into approximately 5,500 individual comments. Responses were received from all 50 states and 89 foreign countries. A summary of the substantive comments and Forest Service responses to those comments can be found in Appendix H.

Key Issues

Any alternative that proposes to change the Forest Plan could affect resources and/or outputs relative to the current Forest Plan. Therefore, Chapter 3 of the EIS shows the effects of the various alternatives on all relevant resources and evaluates their effects relative to all of the issues and concerns previously identified during the 1997 plan revision process. However, based on the purpose and need of this EIS and the public input received during the current EIS process, some issues are more likely to influence the comparison among alternatives and represent the major issues to be evaluated. These issues were grouped into three broad issue categories, referred to as the key issues. These key issues are the major issues driving the alternatives and analyses.

Key Issue 1 – Protection of high value roadless areas from road development and timber harvest activity on the Tongass National Forest is of local and national importance, particularly for wildlife and biodiversity, recreation, and tourism.

Many people believe roadless areas should be allowed to evolve naturally through their own dynamic processes and should be afforded protection that ensures this will occur. The Tongass includes very large undeveloped land areas with several portions of the Forest consisting of contiguous roadless areas that exceed 1 million acres and represent large, unfragmented blocks of wildlife habitat. This large scale of roadless lands does not exist on any other National Forest, except the Chugach National Forest in Southcentral Alaska.

Roadless areas are considered important because of their wildlife habitat and recreation values and their importance for tourism. They are also important because of the passive-use and ecosystem services values they provide.

Passive-use values represent values that individuals assign to a resource independent of their use of that resource. Typically this includes existence, option, and bequest values, and represents the value individuals obtain from knowing that expansive roadless areas exist, knowing that they are available to visit in the future should they choose to do so, and knowing that they are available for future generations to inherit. There is interest in preserving large portions of the Tongass because so much of it is in a natural condition, unlike most other national forests, and because the Forest represents a significant portion of the world's remaining temperate rainforests.

Ecosystem services represent the services provided to society by healthy ecosystems. These services and benefits include what some consider to be long-term life support benefits to society as a whole. Examples of ecosystem services include watershed services, soil stabilization and erosion control, improved air quality, climate regulation and carbon sequestration, and biological diversity.

Indicators: Analysis relative to this issue compares the amount and proportion of land protected in non-development Land Use Designations (LUDs); the amount of inventoried roadless areas that would be protected under each alternative; and the amount of productive old-growth forest that would be protected under each alternative. Also, the values of the lands protected are considered. Non-use or passive-use values are discussed qualitatively and with examples provided from other studies.

Key Issue 2 – The Tongass National Forest needs to seek to provide a sufficient timber supply to meet the market demand and help maintain a vibrant economy in Southeast Alaska.

TTRA (Section 101) requires the Forest Service to seek to provide a supply of timber from the Tongass National Forest that meets the annual market demand and the market demand for each planning cycle, consistent with providing for the multiple-use and sustained yield of all renewable resources. With the cancellation of long-term timber contracts and the closure of two Southeast Alaska pulp mills in the 1990s (discussed in detail in Chapter 3 Environment and Effects), current demand for Alaska's National Forest timber depends on markets for sawn wood and the option of exporting manufacturing residues and lower grade logs. Future or planning cycle demand scenarios cover a wide range of issues and depend on rates of economic growth in key markets, conditions faced by competitors, and the rate of investment and innovation in Alaskan manufacturing.

Over the past half a century, the timber industry has been a major component of the economy of Southeast Alaska. However, with the closure of two Southeast Alaska pulp mills and the growth of tourism, timber has played a lesser role. Because the economy of Southeast Alaska is based on relatively few industries, maintaining an active timber industry is important for maintaining a well-diversified economy.

Indicators: Analysis relative to this issue compares the likely demand for timber based on capacity of the local industry and the amount of harvest made available to meet that demand. It also considers the type of wood (sawlogs and utility wood) made available and the usefulness of that wood type to the local industry, as well as the amount of timber that would be available from state and private sources. Finally, it considers the effects on the regional and national economies and the effects on the local communities.

Key Issue 3 – Protection of the wildlife habitat and biodiversity of the Tongass National Forest is of local and national significance and is affected by road development and timber harvest activities.

The Tongass National Forest supports a unique and important assemblage of wildlife including the largest population of brown bears and breeding bald eagles in the world, species of high importance for subsistence (e.g., Sitka black-tailed deer), an extensive array of endemic mammals and other species, and a large number of species that are at least partially dependent on old-growth habitats (e.g., marten and goshawk). Populations of many of these species and the biodiversity of Southeast Alaska are affected by timber harvest and the development of roads.

Although less than 10 percent of the productive old-growth habitat on the Tongass has been converted to young growth, the percentage is much higher for certain types of old growth, such as lowland and large-tree old growth. In addition, a high percentage of non-NFS lands have been harvested at a much higher rate. Therefore, the cumulative effects of harvest and road building on wildlife in Southeast Alaska are greater than the effects for the Tongass by itself.

Indicators: Analysis relative to this issue compares the amount of productive old- growth forest that would be protected under each alternative, as well as the percentages of biogeographic provinces that would be protected in reserves. It also considers the role of the managed lands (development LUDs) in providing wildlife habitat. It rates the alternatives in terms of the expert panel ratings conducted for the 1997 Forest Plan Revision EIS. Habitat changes, as documented by habitat amounts, changes in road densities, and habitat models are also used as indicators. Finally, cumulative harvest and road development on non-NFS lands is quantified and evaluated in conjunction with harvest and road development on NFS lands.

Appendix B
Modeling and Analysis

Planning Situation

The National Forest Management Act of 1976 (NFMA) directs each National Forest to prepare a comprehensive land and resource management plan. The Tongass National Forest produced its first comprehensive Plan in April 1979. The NFMA also directs that these management plans be revised at least every 15 years. The Tongass began the Revision process in 1987, published a Draft Environmental Impact Statement (DEIS) in June 1990, and prepared the Supplement to the DEIS (SDEIS) as a result of the November 1990 Tongass Timber Reform Act (TTRA). The SDEIS was published in August 1991 and the Revised SDEIS (RSDEIS) was published in April 1996. The Final EIS for the Forest Plan Revision was published in 1997 along with a comprehensive Appendix B that detailed the analytical process followed. In 2002 a Draft Supplemental EIS (SEIS) was published and in 2003 a Final SEIS was developed; an Appendix B for modeling and analysis also accompanied the Final SEIS. The purpose of the 2008 Tongass Appendix B is to present a discussion of the major analytical processes and models used in this 2008 Forest Plan Amendment EIS. Due to the magnitude (17 million acres) and complexity (19 land use designations) of the planning process, a number of analytical methods are used. This discussion includes basic assumptions, modeling components and inputs, rules, methods, and constraints. The information supplements the broader, less technical descriptions included in the body of Chapters 2 and 3 of the EIS. Additional information and documents used in the analysis process are contained in the planning record. The planning record in its entirety is incorporated here by reference.

Spectrum Modeling

Analysis-related Changes between the 1997 and 2008 Final EISs

As the assessment, development, and analysis of geographic information is a continuous process, aspects and attributes of existing databases are continually changing. These improvements and additions to the databases often have direct results on models, model results, and the assumptions used within the models themselves. The years between the 1997 FEIS and this EIS saw a number of changes to resource inventories, coefficient development, and model assumptions, all of which played a role in the recalculation of alternative outputs. These changes are:

Development of a Forest-wide Logging System and Transportation Analysis (LSTA)—A complete and consistent Forest-wide LSTA and Integrated Timber Operability analysis were developed. These products resulted in geographic information system (GIS) layers for all potential harvest units and the roads needed to access them under the current Forest Plan. The harvest units were identified within the mapped suitable land base, as defined by the latest GIS layers. The harvest units and roads were mapped by logging engineers and foresters with knowledge and training in the standards and guidelines. Mapping included identification of the most appropriate logging systems, so that the suitable land base could be apportioned into operability classes. Risk factors were also identified that will be used for refinements to the estimated suitable land base.

Recalculation of the Tentatively Suitable Land Base—More accurate information about the landscape has been captured in the Forest's GIS resource layers (e.g., streams, slopes, karst). This information was used to update the tentatively suitable and the suitable land bases. See Appendix A of the Forest Plan and Chapter 3 of this EIS for more detailed information on how more current information was included in the suitability analysis.

Geographic Zone Recognition—Due to recent analysis that showed significant volume differences between five physical geographic zones on the Forest, the decision was made to recognize cost, price, and volume differences according to these zones. The zones recognized were North Islands, South Islands, North Mainland, South Mainland, and Yakutat. This is distinct from past analyses in which three administrative area differences were recognized.

Commercial Thinning—The interdisciplinary team recognized the option of commercially thinning young-growth stands to achieve volume and/or wildlife goals. This prescription was included in the Spectrum model along with thinning volume estimates derived from the Forest Vegetation Simulator (FVS).

Goshawk and Marten and Legacy Standards and Guidelines—For modeling the current Plan, Goshawk and Marten standards and guidelines were included in the Spectrum analysis. In some of the other alternatives, legacy standards and guidelines were incorporated as a way to leave forest structure after harvests.

Changes to Visual Management System—The Forest completely changed over from the Visual Management System (VMS) to the Scenery Management System (SMS). At the same time, all of the scenery GIS layers were updated. This updating began with the mapping and development of a GIS layer for the Visual Priority Routes and Use Areas (see Appendix F in the Forest Plan). Next Seen Areas, based on these Visual Priority Routes and Use Areas, were modeled using digital elevation models (DEMs) and Distance Zones (foreground, middleground, and background) were mapped based on established criteria. Scenic Integrity Objectives were then mapped for each alternative, based on Seen Areas, Distance Zones, and Land Use Designations (LUDs). The Visual Absorption Capability was remodeled and mapped and based on all of these sources. Regulation Class layers (see below) were developed for use in Spectrum modeling.

Land Adjustments—Since 1997, a variety of land adjustments have occurred. These adjustments have been incorporated into the current analysis as they have affected the total National Forest System (NFS) land base as well as the tentatively suitable and suitable forest land bases.

Modeling Implementation Reduction Factors (MIRF)—These factors, used to adjust model results to account for missing and known data inaccuracies, have been recalculated for each alternative. The MIRF changes have occurred as a result of improved information derived from upgraded GIS layers, including streams, slopes, and karst, a reduction in the lands identified as encumbered, and other factors. This calculation is explained in detail later in this appendix.

Inventory and Data—The inventory step of the planning process consists of the collection, development, and documentation of data to address the public issues, management concerns and resource opportunities, and planning criteria. Two basic types of information are needed to facilitate the analysis and development of alternatives. The first consists of information related to the classification of land into categories with unique properties. This classification can be based on any attribute significant to planning issues. This type of information is tied directly to the map base. In the case of the Tongass National Forest, this map base is its GIS database. The second type of information is not directly tied to a map base, but has more to do with the estimation of how land will respond to certain management activities. This type of information comes from many sources: Regional procedural handbooks, research studies, available literature, etc. The most up-to-date and verifiable information available was used for the EIS. Several Forest-wide inventory data sources have been updated and improved for the 2008 EIS. The primary changes and updates to the inventory, data, and modeling include:

- The timber harvest map was updated to reflect timber harvested through 2006.
- A new coverage was created to better estimate timber volumes. The cover was based on the value and degree of operational difficulty of the timber across the forest. Five unique geographic zones were identified; Yakutat, North Island, North Mainland, South Island, and South Mainland. Additionally, a size-density model (SDM) cover was created based on several landscape features incorporating the Common Land Unit (CLU), National Wetlands Inventory, aspect, and existing vegetation map to stratify old growth into seven unique size density classifications for productive old growth (POG). For modeling and yield estimation purposes, the old-growth stratum was derived from a generalization of the SDM into three volume strata (High, Medium, and Low).

These attributes stratified the Forest Inventory and Analysis (FIA) plots on the forest used in old-growth volume estimates.

- Forest Vegetation Simulator (FVS) model runs were conducted to estimate young-growth yields, including commercial thins. These runs were based off of a combination of FIA and forest-level data collected on young-growth stands.
- Forest-wide LSTA and timber operability analysis were developed (noted above).
- Inventoried roadless area boundaries were changed to reflect new road construction and timber harvest that occurred through 2006.
- New roads were added to the roads data base.
- Changes in land ownership due to conveyances to the state and Native corporations and other adjustments have been addressed in the data base (noted above).
- Improvements and updates have been made to most other resource databases, including tentatively suitable lands, streams, slopes, karst, and other data.
- Development of a completely new set of Scenery Management System GIS layers (noted above).

Modeling Changes—Some of the newly derived and updated information required updates to the Spectrum model formulation (see below for more detailed information on Spectrum modeling). The major modeling changes were:

- Analysis Areas were refined and recalculated for alternatives. See "Land Base Analysis Areas" below for further discussion.
- Young-growth stands were classified into 10-year age categories and by whether they had been precommercially thinned.
- All timber values were recalculated to reflect current information.
- Cost information was updated to reflect current information.
- Management intensity regimes (Regulation Classes – see below) were recalculated for each alternative.
- Watershed constraints were recalculated based on the suitable lands in each alternative.
- Model implementation reduction factors (MIRFs – see below) were updated.
- Incorporation of Goshawk/marten standards and/or legacy standards and guidelines into the Spectrum model.
- Addition of new treatment options including commercial thinning and partial cutting.
- Cost, price, and yield differences recognized by geographic zone rather than by administration area.

The Forest Planning Model (Spectrum)

Spectrum is a vegetation management model developed by the Forest Service Ecosystem Management staff in cooperation with the Rocky Mountain Experiment Station to assist in Plan Revision alternative evaluation. It was designed to fulfill the requirements outlined in the 1982 National Forest System Land and Resource Management Planning Act (36 CFR), most importantly Section 219.12(f)(8): "Each alternative shall represent to the extent practicable the most cost efficient combination of management prescriptions examined that can meet the objectives established in each alternative." Spectrum is the primary modeling tool used to ensure that land allocations and output schedules for alternatives are realistic and meet standards and guidelines in a cost-efficient manner. Spectrum enables planners to create a sufficiently detailed linear model with fairly simplistic data entries.

Spectrum is a derivative of the FORPLAN model used for analysis in the 1986 Forest Plan. Spectrum assumes that relationships between outputs and the land base are linear (e.g., twice the number of similar acres yields twice the timber volume). A management objective is specified (e.g., maximize net revenues from harvesting activity) as well as any constraints that may affect that objective (for example, produce a steady supply of timber over time).

The Spectrum solution process involves three steps: 1) create a linear programming (LP) model, 2) find the optimal solution to the LP model, and 3) put the model solution into a more readable form (i.e., interprets the linear programming results). Spectrum's matrix generator portion translates the management objective, constraints and assumptions about the land base into a matrix of numbers that can be solved with a linear programming (LP) solver software package. The Tongass used the C-WHIZ LP solver software package to solve the matrix generated by the Spectrum model. The solver software determines a system of management prescriptions that results in the highest possible management objective value (e.g., Present Net Value) within the constraint parameters (meeting desired conditions and appropriate standards and guidelines). Spectrum's report writer portion then translates the LP output into reports, such as costs, revenues, landscape condition, and long-term sustained yield capacity.

Results from the modeling process are only approximations of what to expect when any given alternative is implemented. The main purpose of modeling is to aid planners in estimating likely future consequences of management prescriptions. A choice between alternatives can be made even though the model may lack precision in describing specific attributes of a given alternative.

An in-depth technical discussion of linear programming and its use in forest management applications can be found in Davis et al. (2001).

The Tongass Spectrum Models

Large Linear Programming models can be difficult or impossible to solve. Initial size estimates of the Tongass model, given the desired level of detail, made it clear that for each alternative, three Spectrum models would be needed; one model for each of the three old Administrative Areas of the Tongass National Forest (Chatham, Ketchikan, Stikine). To further mitigate model size, Spectrum models for the Tongass only analyze land classified as suitable for timber harvest. Those lands considered "unsuitable" for timber harvest were omitted from the models. The process for determining suitability can be found in Appendix A, "Timber Suitability Classification," of the Forest Plan. Results of each of the Administrative Area models were then aggregated to determine Forest-level quantities and impacts presented in the chapters of this EIS.

Spectrum Model Components

A Spectrum model has five main components: 1) the objective function, 2) land base analysis areas, 3) management prescriptions, 4) activities and outputs, and 5) constraints. The objective function is the overall management strategy objective of the model. Examples of typical objective functions are “maximize present net value,” “maximize timber volume,” and “minimize cost.” Only one objective function can be used for each model run; however, forests typically find it beneficial to use the results of one objective function learn about the specific nature of their management problem or to formulate desired conditions used with another objective function. Detailed information on objective functions used by the Tongass is found in the solution process section of this appendix. The last three components of the Spectrum model greatly influence how the second (the land base) will be defined. The Tongass models are designed to analyze the activities and outputs associated with timber harvest scheduling; therefore, the land base is defined by those characteristics significant to the timber resource. Other resources are dealt with through the LUD allocation process and model constraints. The management prescriptions applied to the Forest differ mostly by rotation age and dispersion amount (portion of the trees removed from the stand). The activities (costs) associated with timber harvesting are well documented as are the outputs (benefits) obtained from the wood fiber. The constraints differ by alternative but often refer to a particular timber classification, specific geographic area, activity or output volumes allowed, and management allocation. Constraints are used to ensure desired condition achievement, compliance with appropriate standards and guidelines, and that the resultant management strategy is feasible.

Land Base Analysis Areas

Analysis Areas represent unique combinations of the different Identifiers used to stratify the mapped suitable land base. The mapped suitable land base is different for each alternative and is derived in

Table 3.13-8 of this EIS. Analysis Areas represent between 378,000 and 1.5 million acres, depending on the alternative. It is important to note that they include the unmapped unsuitable lands accommodated for by the Model Implementation Reduction Factor (MIRF – see below for detailed discussion). If information was perfect, and all unsuitable lands could be mapped, the actual suitable would be somewhat less than the land base represented by the Analysis Areas (similar to figures found in line 13 of Table 3.13-8).

An analysis area is an operational aggregation of land resource polygons that have the same characteristics, are expected to have similar responses management prescriptions, and have similar costs and benefits associated with management prescriptions. By an extension of this logic, analysis areas differ from each other in management prescription response and the costs and benefits associated with those prescriptions. Analysis Areas are unique combinations of the Analysis Area Identifies described below.

Analysis Area Identifiers. The 1996 modeling process determined analysis area identifiers that provided a categorization of the timber base consistent with the timber management analysis nature of the harvest scheduling model used for plan revision. These identifiers were re-evaluated for the 2008 EIS and determined to still be relevant for classifying the land base into areas where the land within an area had similar logging costs and timber values. However, the identifiers were updated and expanded when appropriate to reflect new information or additional levels of detail that are relevant to the 2008 EIS process. Six identifiers were used for input into the Spectrum models: 1) Value Comparison Units, 2) logging operability, 3) productivity group, 4) roaded/unroaded classification, 5) timber strata/volume class, and 6) Regulation Class. A summary of each identifier and why it was selected follows. The identifiers are presented by name in Table B-1.

Value Comparison Unit (VCU). In the current Plan, there are 946 unique VCUs. Each of the VCUs provides Spectrum with a level of spatiality the other identifiers cannot. In previous FORPLAN models, the main spatial identifier was Management Area (MA). Moving to VCU as the spatial identifier increased the resolution of mapping by six times. VCUs can be used to recognize spatially-variable costs such as hauling costs to the appropriate mill, road construction costs, and construction of log transfer facilities. VCUs are also used to formulate management constraints such as old growth retention, goshawk/marten, and legacy constraints, watershed constraints, and dispersion constraints (see constraints section of this appendix for further explanation).

Timber Harvest Operability. Operability, or logging system, was a direct product from the LSTA developed for the Tongass National Forest. Suitable acres on the Tongass National Forest were classified into six operability classifications used in Spectrum; ground-based/shovel, short-span cable, long-span cable, short-distance helicopter, mid-distance helicopter, and long-distance helicopter. Slope was a factor in determining the logging system appropriate for each stand. Lands with a slope > 72% were eliminated from the suitable land base and, therefore, cannot be logged. Lands with slope > 67% are generally to be left unroaded (and are mostly harvested by helicopter) unless no practical alternatives exist. Lands between 35% and 67% slope generally cannot use the ground-based/shovel system, and must use the helicopter or cable system. Lands with < 35% slope can generally be harvested with the ground-based/shovel system. It is easy to see how slope has an indirect effect on the cost of removing the timber from the land; generally, ground-based/shovel systems are the least expensive, followed by cable, with helicopter harvests as the most expensive. Therefore, steeper-sloped areas incur a higher timber harvest cost. Operability also correlates quite strongly with elevation and general accessibility.

Productivity Groups. This land classification is based on the site productivity as categorized in the Soil Mapping Unit (SMU) data base. There are three basic groups that indicate the regeneration potential for future timber stands. Group 1 is the highest productivity class with a minimum site index (SI) of 75. Group 2 is lands with an SI less than 75 that are not Group 3. Group 3 is all lands in the following wetland soil types: Karheen, Kaikli, Maybeso, Kitkum, or lithic Cryosaprist. Group 3 ranges from an SI of 40 (Chatham) to 50 (Ketchikan).

Roaded Classification. This identifier specifies whether an area is presently roaded or unroaded. The road/roadless condition of an area influences the cost of harvesting the timber.

Unroaded areas require more costly road construction; roaded areas require less costly road maintenance and repair when harvesting activities are conducted.

Volume Class/Strata. This attribute was used as an identifier due to its relevance to many forest management considerations. Wildlife habitat and most recreational settings correlate with the vegetation types described by this feature. This attribute was relevant in then Spectrum model to distinguish the logging costs and timber benefits associated with the volumes generated from the different volume classes. There are 12 second-growth strata and three old-growth strata used as Spectrum identifiers. Young growth (or “second growth”) stands are categorized into 10-year age classes between 0 to 80 years old and also by whether they have been precommercially thinned. Old-growth strata include low-volume, medium-volume, and high-volume stocking levels. The strata used for this identifier are obtained from a GIS dataset derived from the Tongass National Forest’s recently derived size density model (SDM).

Regulation Class. This identifier distinguishes the three regulation classes recognized in the model. Regulation class is determined by the combination of Scenic Integrity Objective, LUD designation, Distance Zone and Visual Absorption Capacity. Regulation class affects the intensity of potential harvesting activities. See below in this Appendix for a detailed explanation the Regulation Class process.

Table B-1
Spectrum Level Identifiers

Identifier	Possible Attributes
Value Comparison Unit (VCU)	00 through 3950 (Chatham) 5270 through 8670 (Ketchikan) 3980 through 5260 (Stikine)
Logging Operability	Ground-based/Shovel Short-span cable Short-distance helicopter Long-span cable Mid-distance helicopter Long-distance helicopter
Roaded Condition	Roaded Unroaded
Volume Class/Strata	Young Growth Age 0-9 Young Growth Age 10-19 Young Growth Age 20-29 Young Growth Age 30-39 Young Growth Age 40-49 Young Growth Age 50-59 Young Growth Age 60-69 Young Growth Age 70+ Young Gr. w/ Precomm. Thin Age 20-29 Young Gr. w/ Precomm. Thin Age 30-39 Young Gr. w/ Precomm. Thin Age 40-49 Young Gr. w/ Precomm. Thin Age 50+ Low Volume Old growth Medium Volume Old growth High Volume Old growth
Regulation Class	Regulation Class 1 Regulation Class 2 Regulation Class 3

Modeled Analysis Areas. Once the Analysis Area Identifiers were determined, the next step was to estimate the number of possible analysis area combinations. The maximum number possible is the product of the number of unique elements in each identifier:

> 946 VCUs x 6 Operability Classes x 2 road/unroaded x 3 productivity groups x 12 volume strata x 3 regulation classes = 1,226,016 potential Analysis Areas

The Tongass GIS layers of Analysis Area Identifiers were intersected to result in a Forest-wide total of about 87,500 unique polygons (Alternative 6). However, more than 86,000 of these polygons were less than 100 acres in size. Due to size considerations of the Spectrum model and the fact that, on an operational level, very small areas of land would not be independently managed, it was necessary to generalize smaller polygons and lump them with similar larger ones. Through a process of trial-and-error, an 80-acre threshold was used to create a manageable model size, while still preserving model integrity at a strategic planning level. In other words, all polygons less than 80 acres and within certain guidelines were aggregated into a larger analysis area.

A four-step algorithm was used to take small polygons and lump them with larger ones to create a manageable number of analysis areas. Step 1 combined polygons regardless of size. Steps 2 through 4 generalized only polygons less than 80 acres in size (they could be lumped into an analysis area larger or smaller than 80 acres).

Step 1: Match on all attributes
Some polygons were geographically distinct but not distinct based upon analysis area identifiers. Therefore, the first generalization was that if all identifiers matched between two or more polygons (initial analysis areas), they were combined into one for analysis purposes.

Step 2: Ignore the roaded/unroaded classification
If two Analysis Areas were in the same VCU, had the same operability, regulation class, volume strata, and productivity class, the smaller one was lumped with the larger one.

Step 3: Ignore roaded/unroaded classification and operability classification
After step 2, if two Analysis Areas were in the same VCU, had the same regulation class, volume strata, and productivity class, the smaller one was lumped with the larger one.

Step 4: Ignore volume strata
After step 3, if two Analysis Areas were in the same VCU, had the same operability, roaded/unroaded classification, regulation class, and productivity class, but different volume strata classification, the smaller one was lumped with the larger one. The exception was that old growth was not lumped with young growth and young growth was not lumped with old growth.

Finally, if the analysis area could not be generalized and it was less than 5 acres in size, it was left out of the model. The final number of analysis areas for the Tongass was 5403 (Alternative 6).

A note on the effects of model generalization
As with any model, the Spectrum model is a landscape planning model that relies heavily on generalizations and assumptions. There are many generalizations used in the Spectrum model that affect exactness of the outcome. These factors include generalizations in the GIS maps used to create the analysis areas, aggregation and averaging of FIA stand inventories used to calculate per-acre yields, statistical inference used in calculating the value of harvested logs, statistical inference and generalizations in determining costs of logging, road construction, miles of roads to construct, etc., and simplifying assumptions about the uncertainty of future costs and commodity prices. Analysis Area aggregation is simply another generalization technique used to make the model a manageable size. It is simply not possible without further detailed study to isolate the effect of Analysis Area aggregation on the true value for any given land area/prescription or for the Forest as a whole. It is assumed that the level of detail maintained in the model is accurate enough to give managers enough information to make informed decisions about the alternatives evaluated in this Forest Plan.

Management Prescriptions

A prescription is a management practice or group of management practices applied to a specific land area. The planning process involves assignment of the land base to the available prescriptions. This is facilitated by the Spectrum model. The solution process of Spectrum assigns land to prescriptions based on forest constraints, the given management alternative, and the objective function.

Prescriptions were developed by the interdisciplinary team to represent the full range of possible management activities and outputs. Since the Tongass models are concerned primarily with timber harvest scheduling, only prescriptions related to timber harvest were modeled. The interdisciplinary team quantified the outputs, costs, and benefits that would occur when these timber prescriptions were applied to a given analysis area. This quantification process produced the output, cost, and benefit coefficients that are used in Spectrum yield and economic tables. The interdisciplinary team, during its development of standards and guidelines for all prescriptions, ensured that the specific management requirements set forth in 36 CFR 219.27 would be met in accomplishing the goals and objectives for the Tongass.

Spectrum prescriptions were developed to allow consideration of a full range of management activities in the analysis areas. A minimum level or no-harvest prescription was created for each analysis area as well as several different harvest options. The only criterion used to eliminate timber options from the models was technical feasibility. For example, ground-based/shovel logging was not considered on slopes greater than 35 percent. Consideration of timber prescriptions for any given Analysis Area was not directly limited by economic efficiency, in order to allow they may be chosen in efficient fulfillment of a forest-wide desired condition (CFR 219.14(f)(8)). Available timber options were not eliminated from consideration because they produced a negative Present Net Value (PNV) or even a lesser PNV than some other timber option. A full range of timber options with varying levels of economic efficiency was available to the model, and the Spectrum model was able to consider the economic efficiency of each prescription during the solution process. The Spectrum prescriptions analyzed are briefly described below.

Minimum Level/Maintenance. Applies minimum custodial direction for the timber resource. There is no commercial timber harvest and no production of outputs related to timber harvest. This is the prescription assigned to lands not scheduled for timber harvest

Clearcut. Removal of all merchantable commercial trees within a stand in one operation. The regenerated stand receives no thinning activities before the next clearcut.

Clearcut with precommercial thinning. Removal of all merchantable commercial trees within a stand in one operation. The regenerated stand receives a subsequent precommercial thin at 20 years of age.

Clearcut with commercial thinning. Commercial thin at age 70, 80, or 90. Clearcut at choice of rotation ages. Applies to Productivity Class 1 lands, Regulation Classes 1 and 2.

Clearcut with precommercial and commercial thinning: Precommercial thin at age 20. Commercial thin at age 60, 70, or 80. Clearcut at choice of rotation ages. Applies to Productivity Class 1 lands, Regulation Classes 1 and 2.

Small-group selection and uneven-aged harvesting. The objective of this prescription is to create uneven-aged stands with regeneration of desirable species. Trees are harvested individually or in small groups normally from 0.5 to 5 acres in size. Timber production is not the primary management emphasis in these areas (emphasis is recreation, scenery, fisheries, and/or wildlife). Applies to Regulation Class 3.

This prescription is modeled as a series of removals that occur every 50 years and remove 25% of the volume at every entry. For old-growth stands, accounting rows (reflecting standing volume) in these yield tables show the combination of remaining old growth plus assumed regrowth of the small patch. Green-up interval is implied by the regulated scheduled entries (50 years); rotation age will be 200 years. Existing young-growth stands in Regulation Class 3 are modeled in a similar manner as the old growth; 25% of the volume is removed upon first entry (starting age 80) and 25% is removed at second entry, etc.

Old Growth Two-Aged Management (Partial Cut). This prescription was developed for areas where goshawk and marten standards apply. On first entry into old-growth stands, 75% of the land area is harvested (75% of the standing volume). The stand is then considered "regenerated" and second-growth activities are allowed on the cut portions of the stand starting at age 80. Standing volume is a function of remaining old growth plus assumed regeneration. Regeneration volume is approximately 10% less than full young-growth volume, due to the increased shading from reserve trees. This prescription is available to Regulation Class 1 and 2, Productivity Classes 1 and 2 Old-Growth High volume strata only. This prescription is applied to Alternative 5 VCUs with goshawk/marten standards when more than 33% of the POG within a VCU has been regenerated.

Activities and Outputs

Activities are the costs associated with Spectrum-assigned timber harvests. Outputs are the timber volumes and prices associated with the same harvests. Each Activity and Output used in the model is described below.

Activities (Costs). All costs and values used in the Spectrum analysis are based on collected values (2004). In order to reduce the number of numeric tables in this appendix, only average and summarized values are used in this section. The actual cost figures used in the analyses are available in the planning records.

Coefficient Development and Estimation of Effects. The GIS enables identification and stratification of land into logical groupings. The response of these groups to management activities was determined from a wide variety of existing data. All coefficients and assumptions made in the modeling process have been developed from the following information sources.

Sale Preparation and Administration
Information Sources: Tongass National Forest, historic actual expenditures and accomplishment data, declaration of Forrest Cole, July 2004.

Occurs With: Thousand board feet of net sawlogs removed from the stand.

Assumptions*:* This is the cost to the Forest Service of administering and laying out timber sale areas. A single coefficient was used to estimate timber sale preparation and administration costs: $32/MBF.

Log Transfer Facility (LTF)
Information Source: The forest GIS coverage of existing and proposed LTFs. Costs and construction levels are based on historic costs experienced in the past 5 years of construction contracts and adjusted with Region 10 construction cost guide information.

Occurs With or Varies By: Acres harvested.

Assumptions: Using the LTF map and database, each LTF, existing or proposed, was assigned to the appropriate VCU. Appropriate mathematical adjustments were made for VCUs that access more than one LTF, or LTFs that service more than one VCU. LTF costs used in Spectrum are an average of total cost of the LTF to be constructed divided by the number of suitable acres in that VCU. The cost is incurred at time of harvest. LTF Construction costs are classified by 4 different categories to reflect the total cost of constructing the LTF.

Category 1: Existing LTF constructed/used within last 10 years = $50,000
Category 2: Existing LTF constructed/used more than 10 years ago = $125,000

Category 3: New Construction (large) (>30 MMBF total volume) = $175,000
Category 4: New Construction (small) (<30 MMBF total volume) = $125,000

LTF Camp/Commute
Information Source: Based on most recent published collected costs, Region 10 Forest Management (2004).

Occurs With or Varies By: Acres harvested. Varies by VCU.

Assumptions: The cost is incurred at the time of harvest. Each LTF used by a VCU was identified as either needing to maintain a camp, pay for a significant commute, or be free of this cost. Average camp cost per MBF is $15. Average commute cost is $7 per MBF. Weighted averages assigned to all acres of a VCU were used when not all acres of a VCU require LTFs to incur camp or commute costs.

Road, Raft, and Barge Haul
Information Source: Road haul costs are an average for the forest based on most recent published collected costs (2004). Raft and barge haul distances are based on a GIS analysis of LTFs and existing and/or potential mill locations. Barge and raft haul costs are calculated by a formula based on regional published costs.

Occurs With or Varies By: Value Comparison Unit (VCU). Costs are based on the volume (thousand board feet) removed from the stand.

Assumptions: Hauling cost includes all anticipated modes of transport likely used to transport logs from the landing to the mill. This may include road, barge, and/or log raft. Road haul is the cost of transporting logs by truck to either the closest LTF or mill. Road haul costs represent the forest-wide average haul cost per MBF volume removed based on average haul time. The average Road Haul cost is $24 per MBF. Barge haul is the cost of barging logs from the site or the LTF to the appropriate mill. Raft haul is the cost of building rafts out of the logs and hauling them to the appropriate mill. Raft haul cost may only be used in higher-demand alternatives, assuming the construction of new Medium Density Fiberboard (MDF) plants. Appropriate mathematical adjustments were made for calculating the haul costs for alternatives that incurred haul costs for utility wood vs. those Alternatives that left the utility wood at the site.

The distance to the nearest sawmill was determined for each VCU as VCUs are geographically distinct. For alternatives that recognized the eventual existence of Medium Density Fiberboard (MDF) plants, there were potentially two distances calculated for each VCU – one from the VCU's LTF to the sawmill and one from the LTF to the MDF plant. This distance was then used in a formula to calculate the total cost per thousand board feet (MBF) of the timber sale.

Formula: ((((RTD/M)*C)/B) + F)/(1-SD)

Where:
RTD = Round trip distance (unique for each VCU – twice the distance from the LTF to the mill)
SD = Scaling Defect (unique based upon age of the stand, volume strata, and geographic zone).
C = Cost per hour of operation ($182.50)
B = Average MBF on the barge or raft (238)
M= Miles per Hour (6.9)
F = Fixed costs ($33.72)

By inspection, one can see that when all other factors are held constant, logs traveling a greater distance to the mill incur a higher per-MBF transportation cost. This relationship is not exact, however, in that different VCUs were determined to have different Scaling Defects (SD) which may mitigate or exacerbate the transportation costs due to proximity to the mills.

Road Construction, Maintenance, and Repair

Information Source: The extent of Road construction and maintenance and repair needs are based on total projected road miles and the total suitable land base. Costs required for different regulation class lands are derived from the linear grading road construction calculations within the Construction Cost Guide. Road construction and maintenance and repair costs are obtained from the Construction Cost Guide calculations, compared to the costs for construction of roads, over the past 5 years, for public works and timbersale contracts. Road maintenance that occurs during logging operations is included in logging costs.

Occurs With or Varies By: Cost varies by Regulation Class. Miles of Road Construction and/or Maintenance and Repair vary by Roaded status and Regulation Class within each VCU.

Assumptions: All harvest requires some road construction and maintenance and repair. If the area is classified as roaded, then the majority of the activity is road maintenance and repair. Otherwise, road construction is the primary activity. The amount of road construction or maintenance and repair required depends on the geographic location of the harvest area. Each VCU has a distinct roading requirement coefficient. This coefficient is in the terms of miles of roads required to access 1 acre of timber land. The average construction and maintenance and repair for the Tongass is approximately seven miles of road per 1,000 acres (this does not include temporary roads). Maintenance and repair is the only activity necessary once timber harvest is comprised solely of regenerated timber stands because the roads were assumed to be built to the stands for the first harvest.

The timing of construction and maintenance and repair activities and costs varied by management prescription:

- Even-aged prescriptions without commercial thinning incur road construction and maintenance and repair costs as necessary upon first harvest. Upon subsequent harvests, these prescriptions incur the sum of the initial construction and maintenance and repair costs as maintenance and repair costs.
- Even-aged prescriptions with commercial thinning incur road construction and maintenance and repair costs as necessary at the time of the thin. When the stand is regenerated, roads maintained and repaired at thin will be maintained and repaired and roads constructed at thin will be maintained and repaired.
- The partial-cut prescription works as the even-aged prescription, except in that even though only a portion of the area is treated by this prescription, the full cost for the total area is incurred.
- The Regulation Class 3 prescription works similar to the even-aged prescription; roads are constructed and maintained and repaired upon first entry and they are all maintained and repaired upon subsequent entries.

Road construction and reconstruction costs are obtained from the Construction Cost Guide calculations, compared to the costs for construction of roads, over the past 5 years, for public works and timber sale contracts. Road construction costs are dependent on slope; steeper slopes have a higher road construction cost. Construction costs are exactly calculated for each Regulation Class and Roaded status type within each VCU in order to accommodate the different slopes in these classes between VCUs. The Forest-wide road construction cost is $185,000 per mile and maintenance and repair costs are $50,000 per mile. Road construction/maintenance and repair miles needed for harvests are exactly calculated for VCUs with 100 or more acres of suitable land. For VCUs with less than 100 acres, an average for the administration area was used to mitigate small mapping errors and miscalculations that may occur with small areas.

Regeneration Certification

Information Source: Tongass National Forest, average cost

Occurs With or Varies By: Acres harvested with an even-aged prescription

Assumptions: Occurs for every acre harvested and the cost is incurred at time of harvest. This activity usually takes place from 3 to 5 years after harvest, but because modeling is done on a decadal basis the cost is incurred at time of harvest. It also is assumed that all stands will be certified as regenerated by year five. According to the Tongass silviculturist, when planting occurs, it costs $200/acre. However, only about 3% of treated acres need to be planted. Therefore, the average planting cost of all treated acres is $6 per acre. Planting on Regulation Class 3 lands or in partial cuts is adjusted by the percentage removed (i.e., if a partial cut is 75% of the acre, 75% of the planting cost is incurred). In addition to planting costs, there is a regen/survey cost of $18 per acre that will be included with this cost. The total planting cost used in Spectrum was $24.

Precommercial Thinning
Information Source: Tongass National Forest, implementation cost data based on Region 10 budget allocation

Occurs With or Varies By: Acres receiving a timber prescription permitting this activity.

Assumptions: The Tongass has an active program of precommercial thinning. This improves the health of the stand and permits greater understory development for wildlife. This thinning operation is termed "precommercial" because no revenues are derived from the sale of the harvested trees. The average cost for precommercial thinning on the Tongass is $550 per acre. This silvicultural activity is generally conducted when the stand is between 10 and 20 years old and modeled to occur at age 20.

Yarding/Logging Costs
Information Source: Calculated using procedures in FSH 2409.22 -- Timber Appraisal Handbook.

Occurs With or Varies By: Varies by volume class, logging operability, geographic zone, productivity group, stand age, and prescription. This cost is incurred according to net sawlogs removed per acre and net utility volume removed per acre.

Assumptions: These costs include road maintenance relative to logging, profit and risk relative to yarding, landing construction, and yarding. Logging costs increase as operability becomes more difficult. The logging operability classification of the area heavily influences the logging costs due primarily to the different harvest systems required. The size of the logs influences logging costs. Typically, larger logs result in less logging cost per 1,000 board feet. Volume class, productivity group, stand age, and the use of precommercial thinning is used to estimate the average log size and volume per acre for each unit.

Logging systems include ground-based/shovel, short-span cable and long-span cable. Helicopter costs will also be determined by three categories of distance (0.5 mile, 1.25 mile, and 2+ mile). Helicopter costs are constant costs independent of volume strata and geographic zone, so they can be applied wherever helicopter logging must be used. Young-growth harvest costs were determined initially from FVS outputs at age 80. They were then adjusted for geographic zone, age, and prescription (i.e., clearcut or thin) using South Islands (POW, where the data was collected) as a reference point. Cost curves from 1996 were used as the basis of this adjustment.

Felling and bucking coefficients
Information Source: Based on most recent published collected costs, Region 10 Forest Management (2004).

Occurs With or Varies By: Tracked on a per volume basis (MBF). Varies by Geographic zone and volume class.

Assumptions: Felling and bucking costs were split out separately from logging costs. Costs varied by Geographic zone and volume strata. The forest-wide average felling and bucking cost was $47 per thousand board foot volume.

Outputs(Benefits). The economic benefits associated with timber harvest are based on appraised value. Value is based on tree size, species composition, amount of defect, and other factors. Timber benefits are measured as pond log value. Pond log values used in the Spectrum model are the estimates of price a timber buyer would pay for a log at the mill site, less the markup charged by the logger (profit and risk). To get the stumpage value of this log, all estimated costs that are incurred to get the log to the mill must be subtracted from the pond log value. The resulting stumpage price is assumed to be the price the timber buyer pays for the log (bid price). Bid price represents money to the U.S. treasury.

Sawtimber (board feet and cubic feet)
Information Source: Timber values were determined using timber appraisal methodologies for Southeast Alaska (FSH 2409.22). Values were derived from historic cruise database based on actual collected values (2004). Merchantable volume of existing old-growth timber stands was based on FIA plot analysis by volume strata within each identified Geographic Zone. Yields for regenerated second growth timber stands were derived from permanent study plots and the FVS yield table generation program.

Occurs With or Varies By: At harvest, the volume of merchantable timber produced generates a per mbf revenue that varies by Geographic Zone and volume class. Geographic zone affects this revenue due to differences in species composition and wood quality.

Assumptions: For existing stands, piece size and species composition is determined from a tree-by-tree analysis of the FIA plot summary data. For regenerated stands, piece size and species composition is based on a tree-by-tree analysis of the FVS model outputs. It is assumed that existing old-growth volumes are constant (i.e., through time, growth equals mortality). Young-growth (regenerated) stands grow at a rate determined by the FVS model. The average old-growth pondlog value is $273 per mbf, which is adjusted for profit and risk (economic benefit, or profit, to the logger). Young-growth sawtimber pond log values are also adjusted for profit and risk.

Utility Volume (board feet and cubic feet)
Information Source: No value for utility wood is recognized for Alternatives 1, 2, and 3. Values for Alternatives 4, 5, 6 and 7 are based on Medium Density Fiberboard pond log calculations. Source: "Technical & Economic Feasibility of Constructing a Medium Density Fiberboard Plant in Southeast Alaska". Leonard Guss Associates, 31 May, 2005 and discussions with Dr. Allen Brackley, USDA Forest Service, Sitka Wood Utilization Center. Average percent utility volume was derived using timber measurements methodologies developed by the Region 10 Measurements Specialist. Merchantable volume of existing stands is derived from an analysis of FIA plots located within the suitable land base of the forest. Volume of regenerated stands is obtained from the FVS.

Occurs With or Varies By: At harvest, the volume of merchantable timber produced generates revenue that varies based on Geographic Zone and volume class. Geographic Zone affects this revenue due to differences in species composition and quality.

Assumptions: For existing stands, piece size and species composition is determined from a tree by tree analysis of the FIA plot summary data. For regenerated stands, piece size and species composition is based on a tree-by-tree analysis of the FVS model outputs. It is assumed that existing old growth volumes are constant (i.e., through time, growth equals mortality). The utility volume from regenerated stands is assumed to be negligible and is therefore not counted, whereas the utility component of existing old growth stands averages 16 percent. This difference results from the mixed diameter distribution of old growth stands and the impact of defect to potential sawlogs. The average utility log pondlog value is $72 per mbf, which accounts for profit and risk.

Spectrum Constraints

Constraints in a linear programming model are the rules that must be followed when determining an optimal problem solution. Without constraints, the solution of a Spectrum model may represent a management strategy that is impractical, inconsistent with the forest plan, or in conflict with Forest Service policy. Thus, constraints are included in Spectrum models to ensure that their results are useful and meaningful.

There are two categories of constraints within a Spectrum linear matrix: implicit and explicit. Implicit constraints are common to all Spectrum models. For example, all acres in the model must be allocated to some prescription (even if it is the “no management” prescription), or the number of acres assigned to each prescription must not be negative. These types of constraints are exercises in logic and need not be discussed further.

Explicit constraints are those constraints added to Spectrum models by planners. These constraints come in many forms and are applied to mimic regulations and laws such as NFMA, standards and guidelines set forth in the forest plan, and on-the-ground operating conditions. An example is the non-declining yield constraint. Proven ability to maintain a constant flow (non-declining yield) of harvested timber volume in perpetuity is Forest Service policy. A constraint is added to the Spectrum data set that forces all timber harvest volumes to be at least as great as the previous decade's harvest volume (see below for further discussion). Another example may be a constraint that forces a certain area to be managed specifically for wildlife habitat. There are many explicit constraints in the Tongass models. They vary by land attributes, geographic area, and by management alternative. The explicit constraints used in the Spectrum models fall into two categories: timber policy constraints and operational constraints. A detailed discussion of the intent of these constraints follows. They are summarized in Table B-2 for comparison of their application across the alternatives.

Timber policy constraints. These constraints are included in the Spectrum models to represent legal or policy requirements of national forest timber management. The primary requirements regarding timber management incorporated into Tongass Spectrum models are:

Non-declining Yield. The Tongass models have a constraint that ensures harvest volume (in board feet) will not decline in any decade over the 160-year planning horizon per national policy. Harvest volumes may increase, but all subsequent harvests must be at least as much as the previous decade’s harvest.

Sustained Yield. The harvest in any decade of the planning horizon must not exceed the Long-Term Sustained Yield that can be maintained on the forest. Long-term sustained yield is measured in cubic feet. It is calculated as the average yearly volume yielded from a chosen management action, summed across all management actions for all stands chosen by the model. For instance, if a management action yields 50 cubic feet every 100 years, the Long-Term Sustained Yield for that management action is 0.5 cubic feet per year.

Culmination of Mean Annual Increment. The age at which a managed stand is harvested is called the rotation age. Agency policy is that rotation age can be no earlier than the age at which 95% of culmination of mean annual increment (CMAI) occurs. CMAI is the age at which the stand achieves its highest average volume. The Spectrum models have constraints that allow timber harvest only when a stand has reached 95 percent of this CMAI age. On the Tongass, this translates to a range of rotation ages of about 60 to 170 years. CMAI varies by stand productivity, management prescription, and administrative area and is calculated using merchantable cubic foot volume.

Table B-2
Timber Policy and Operational Constraints Used for Spectrum Modeling

Constraint	Description	Variation Among Alternatives 1	2	3	4	5	6	7
Non-declining Yield	Ensures that a Decade's total harvest volume is at least as much as the previous decade	These constraints are identical between the Alternatives						
Sustained Yield	Prevents the model from harvesting all available timber in the last planning period - limits it to Long-Term Sustained Yield or less	Calculated for each Alternative - Applied the same way*						
Culmination Mean Annual Increment	Prevents the model from harvesting a stand before 95% CMAI is reached	These constraints are identical between the Alternatives						
Strata Harvest Control	Limits the harvest of Old Growth High Volume to their proportion of the total	Calculated for each Alternative - Applied the same way*						
Logging Operability	Limits harvest in Normal Operability (NIC I) to its proportion of the total	Calculated for each Alternative - Applied the same way*						
Watershed Entry	Limit the model to 20% of any watershed less than 30 years old	Calculated for each Alternative - Applied the same way*						
Precommercial Thinning	Limits the total amount of precommercial thinning to a feasible level - 6300 acres per year	This constraint is identical between the Alternatives						
Minimum Timber Constraint	Sets the minimum amount of volume to harvest in certain decades; this is a desired condition of the Alternative	Calculated for each Alternative - Applied the same way*						
Regulation Class 3 Harvest	Limits harvest in Regulation Class 3 to historic proportion of the total	This constraint is identical between the Alternatives						
Goshawk/Marten, Legacy, Retention Standards and Guidelines	Cause the model to accommodate the appropriate standards and guidelines of the Alternative							
	Goshawk/Marten	No	No	No	No	Yes	No	No
	Legacy	Yes	Yes	Yes	No	No	Yes	No
	Old Growth Retention	No	No	No	Yes	No	No	No
Regulation Class Management Intensity	Cause the model to implement the correct management scheme for each Regulation Class	These constraints are identical between the Alternatives						
Modeled Implementation Reduction Factor (MIRF)	Accounts for unmappable unsuitable lands	These constraints are identical between the Alternatives						
Dispersion and Adjacency	Controls on management intensity in the different Regulation Classes	Calculated for each Alternative - Applied the same way[1]						

[1] The constraint level is unique for each alternative but it takes the same form (e.g., High Volume Strata < X, where "X" is unique for each alternative)

Operational Constraints. These constraints are added to Spectrum models to ensure that the results fall within certain Forest-derived guidelines and objectives. Many of these constraints are included to ensure the Forest Plan standards and guidelines are followed. Others are included to make sure the model is "well-behaved." The term well-behaved means that Spectrum results are reviewed for any operationally impossible solutions and constraints are added to deal with these. An example may be the harvest of all of the high-volume strata in the first two decades of the planning horizon. The "strata harvest control constraints" are then added to address this problem (see below). The operational constraints used in the Tongass Spectrum models vary slightly by alternative but are used primarily to control the spatial and volume components of timber management. These constraints are summarized below.

Strata Harvest Control Constraints. In order to ensure that the model does not cut all of the most valuable timber early in the planning horizon, each model is constrained so that the proportion of harvest in the highest volume strata does not exceed the proportion of that stratum in each administration area. This prevents the model from harvesting all of the most desirable timber in an unsustainable way. This constraint is adjusted to account for the type of land (volume class mix) available in each alternative. For Alternative 5, this constraint limits the harvest of the high-volume strata acres to less than 43 percent of the total harvest of all old-growth acres.

Logging Operability Constraints. The forest has three general classes of logging operability derived from six specific classes of operability. The general classes are normal, difficult, and isolated, and the six specific classes are ground based/shovel, short span cable, long span cable, short distance helicopter, medium distance helicopter and long distance helicopter. Shovel, short span cable and short distance helicopter were considered “normal” operability, long span cable and medium distance helicopter were “difficult” and the long distance helicopter was “isolated.” To ensure that the model does not cut all of the cheapest, most accessible acres early in the planning horizon, constraints were added to disperse harvest to the difficult and isolated operability areas in proportion to their occurrence within each Administrative Area. These constraints vary by alternative due to different LUD applications but, in general, limit harvest from normal operability areas to no more than about 90 percent of total harvest acreage per decade.

Watershed Entry Constraints. In order to minimize cumulative watershed impacts from harvest operations, constraints are included to restrict the number of acres that are in an open state in any time period. In general, these constraints limit total harvest acres in any 30-year period to less than 20 percent of the total watershed land area. Because the Tongass models use VCU as the primary land attribute, these constraints are entered for each VCU. Coefficients had to be calculated in each VCU in order to accommodate the fact that only suitable acres are included in the Spectrum model and are only a portion of the total area of most VCUs. In instances where suitable acres are less than 20% of the total acres in the VCU, the constraint will never be violated—even if all suitable acres are harvested. Therefore, these constraints are constructed based on total acres [ownership] in the VCU relative to suitable acres with the following formula:

$C = .2 * T / s$

Where C = constraint percentage, .2 is the 20% limit, T is total acres in the VCU, and “s” is the number of suitable acres.

As an example, consider a VCU with 100 total acres, but only 50 suitable acres. C = .2 * 100/50, or 40%. The constraint added to the model would be 40% of the 50 acres, which is the same as 20% of the 100 acres. Only constraints where C is less than 50% will be applied in order to mitigate model size, based on the assumption that Dispersion and other constraints will cause these constraints to be redundant where C is greater than 50%.

Precommercial Thinning Constraint. All alternatives are limited to a maximum precommercial thinning of 6,300 acres per year. This is the amount that Region 10 considers feasible given budget and personnel limitations. A recent Region 10 report shows that the Forest has treated between 3,500 to 5,500 acres per year (2003-2006). It is recognized that this is not a maximum feasible amount, but suggests that 6,300 is a reasonable estimate of the maximum amount possible.

Minimum Timber Constraint. All alternatives are constrained to meet at least the timber demand associated with the alternative being modeled. This helps to ensure that a full range of ASQs are explored during the decision-making process. These constraints are formulated on the basis that alternatives have been developed to evaluate different possible timber demand scenarios. Therefore, the level of timber demand in an alternative is viewed as a desired condition of that alternative.

Regulation Class 3 Constraints. Of the acres clearcut during the planning horizon, no more than 7% of them can be from lands in Regulation Class 3. This constraint is based on the historic level of harvest on marginally economically viable lands adjacent to normal timber sales. This constraint prevents the model from scheduling impractical amounts of Regulation Class 3 lands in later decades.

Goshawk/Marten Constraints. These constraints apply to Alternative 5 at the VCU level. The amount of POG that can be harvested before these guidelines are enforced is used to constrain the number of acres that can be clearcut in each applicable VCU. Once that threshold is reached, lands may only receive a less intensive treatment (Old-Growth two-aged management – see "Management Prescriptions" above)

Legacy Constraints. Alternatives 1, 2, 3, 5, and 6 incorporate the legacy constraint instead of the goshawk/marten constraints. This constraint requires 30% of the stand to be left unharvested in 49 VCUs on the Forest that have experienced high rates of past harvest. It is modeled in Spectrum using volume. This simulates leaving the appropriate number of legacy trees at the time of harvest. The constraints apply in perpetuity; if the regenerated stand is harvested later in the planning horizon, it is assumed that the same trees (or appropriate substitutes) will be left living at the site.

Old Growth Retention Constraints. These constraints are applied to Alternative 4. Alternative 4 includes old-growth reserves in four biogeographic provinces and an old-growth retention strategy in the others. Reserve areas are excluded from the model, and the retention strategy is modeled with a series of constraints.

The alternative framework says that within each VCU where timber harvest is scheduled, the following constraints should apply:

1) Harvest no more than 50% of the POG during any 50-year period
2) Retain a minimum of 33% of the VCU in an old-growth forest condition

Constraint 1 is formulated based on the amount of 2006 suitable POG relative to the amount of POG present in 1954 (represents the "original" amount of POG present). If the amount of suitable POG in 2006 is less than 50% of the total amount of 1954 POG, there is no danger of violating Constraint 1, and therefore the VCU is not constrained. In the remaining VCUs, the constraint was formulated so that no more than 50% of the 2006 suitable POG could be harvested in any 50-year period.

Constraint 2 was formulated based on how much of the remaining suitable POG could be harvested before 67% of the 1954 POG was harvested. If it was possible to harvest enough suitable POG to cross the 67% threshold, the constraint was set so that harvest would stop once 67% of the POG was removed. Otherwise, the constraint was not necessary as one could harvest 100% of the remaining suitable POG and still leave 33% or more of the 1954 POG in the VCU.

Model Implementation Reduction Factor Constraints (MIRF). These constraints are designed to accommodate for unmapped unsuitable lands that were missed during the suitability determination. It is assumed that when harvest activities occur, a certain percentage of the assumed suitable land will be off-limits for management due to several economic or ecological considerations. These constraints are applied to each old-growth volume strata of each of the six operability harvest systems as well as to young-growth stands. The constraint is implemented by forcing the model to never harvest a certain percentage of the acres in the model. The effect is to control the maximum amount of acres from the suitable land base that are actually harvested. See below for a discussion of how MIRF factors were determined.

Dispersion and Adjacency Constraints. To meet visual quality and Regulation Class objectives, dispersion and adjacency constraints were incorporated into the models. "Dispersion" refers to spreading harvests across the landscape rather than focusing all activities in a concentrated area. The dispersion limits are taken from proxies developed by Tongass landscape architects for each LUD. These visual guidelines estimate how much of a viewshed can be "disturbed" at any one time and still meet the adopted scenic integrity objectives of the area. They also specify length of time before harvest of adjacent units is permissible and the maximum size of these harvest units. Table B-7 (below) shows the constraints that were used for each Regulation Class. The "Visual Disturbance" factors were used in the constraints section of the model and the "Adjacency" definitions were defined in the outputs section of the model. Together, these two definitions (as well as treatment options available to each regulation class) distinguish the regulation classes in the model. Detailed information about these constraints is found in the "Regulation Class" section of this appendix (below).

Spectrum Solution Process

The following sections describe some of the steps involved in solving the Spectrum models. The concept of "objective function" is discussed as the final model component. Following that is a brief discussion of how the Tongass evaluated economic efficiency of the alternatives. Last is a discussion of how the Spectrum model was used to gain insight into the management situation of each alternative and make more informed decisions.

Objective Functions

The objective function of a linear programming model defines the overall management objective of the forest quantitatively. It is generally expressed as a "minimize" or "maximize" function. The LP solution software finds the largest (or smallest) value possible of the objective function within the boundaries of the model constraints. Linear programming principles guarantee that the solution is optimal; that is, the best answer possible. Several different objective functions were used to explore the nature of the Tongass management problem. While only the "maximize present net value" objective function was used for the final results, the other ones may have been used at intermediate steps in the analysis process. Some of the objective functions used in the modeling process include:

Maximize Present Net Value. Present Net Value (PNV) is defined as the benefits less the costs of a management prescription, discounted at 4% annually to the present day, summed over all management prescriptions of all Analysis Areas. Because the model is formulated in 10-year time periods, discounting is done from the middle of each period. This is the objective function that was used for all final model runs presented in this Final EIS.

Maximize Timber Volume. Timber volume is tracked for each management action of each Analysis Area and the total amount is maximized. Several forms of this objective function were used; maximize timber volume in a given period or span of periods, maximize the sawlog component of the total timber volume in a given period or over a span of periods, or maximize the volume from an operability class in a period or span of periods. This objective function was used to ensure that desired levels of timber could be achieved. These runs were also used to proportionally allocate the Alternative demand level across the three Administrative Areas based on each area's potential. However, the maximize timber runs were not used as the final models evaluated in this EIS.

Minimize Harvest from the Unroaded Areas. This objective function was used to determine a management strategy that would meet the desired timber demand level by building as few roads as possible. It was used to help determine appropriate levels of suitable lands in some alternatives.

Minimize Old-Growth Harvest. This objective function was used to determine the minimum amount of old-growth harvest that would sustain the desired timber demand level of an alternative. This information was not used in the final analysis of any alternative, but rather was an intermediate step.

Iterative Process

The Spectrum model was used to test the assumptions and problem formulation strategies used in this analysis. Model outputs were generated and assessed to strengthen the validity of the model. For instance, if it was noticed the model was capitalizing on a certain commodity early in the planning horizon that was out of proportion with a likely feasible implementation (for instance, the model tends to high grade when given the opportunity), the model could be constrained appropriately. Additionally, the Spectrum model was used to formulate feasible constraints in the model. An objective function of "minimize harvest from unroaded areas" can be used to determine the minimum number of unroaded acres that need to be kept in the model to meet the desired demand level. If desired, excess acres could then be constrained to no management or removed from the suitable land base. Timber maximization in later decades can be evaluated to explore trade-offs between harvesting the timber early vs. saving inventory for later decades. If a model solution was infeasible (there is no management strategy that does not violate at least one constraint), the limiting constraints were identified and adjusted appropriately.

One of the strengths of Spectrum or any Linear Programming model is the ability to analyze marginal costs associated with the different constraints. If a solution space is very narrow (there are very few decisions that result in a feasible management strategy), the marginal costs of the constraints can be analyzed to determine which are the "bottlenecks," or constraints that have the largest impacts on meeting the objective. The problem can then be reformulated by relaxing these constraints if desired.

Economic Efficiency

The Spectrum model was used to help measure the economic efficiency of the timber management activities of each alternative. Timber management activities can be thought of as a portion of the net public benefits associated with each alternative. Net public benefits are the "overall long-term value, to the nation, of all outputs and positive effects (benefits) less all associated Forest inputs and negative effects (costs) whether they can be quantitatively valued or not" (36 CFR 219.3). Net public benefit represents the sum of the net value of priced outputs plus the net value of non-priced outputs. The EIS Chapter 3 explains and describes the elements of public benefits that may be a function of Forest planning and management activities. In the Tongass Spectrum analyses, the only economic efficiency directly considered was related to timber management.

Present Net Value Formulation. Economic benefits from the Spectrum model were calculated as Present Net Value, or PNV, of the scheduled timber management activities. This calculation was done by the Spectrum model using pond log values, costs to the logger, and costs to the agency for administering the sale. The formula used to calculate the PNV of each potential management prescription is:

$PNV = [PLV – LC – AC]/(1 + d)^t$

PLV = pond log value (adjusted to exclude logger profit and risk)
LC = Logging costs (operability, haul, LTF, camp/commute, felling and bucking, road building)
AC = Agency costs (regeneration certification, sale preparation and administration)
t = time (year) of harvest into the future
d = discount rate (4% annually)

The dollar values of outputs used to calculate PNV in the Spectrum model are pond log values measured at mill sites less the profit and risk to the seller. The costs weighed against these values included all of the expenses incurred from removing the timber from the site to the mill (logging costs, haul costs, LTF costs, road building costs, etc. – see above). This is a more detailed approach than a typical Spectrum application, but is done so to account for the variability in stumpage values that occur over such a large land area that is the Tongass National Forest. Stumpage value is the value of the timber at the site and is considered receipts to the federal government for a timber sale. In other words, it is what a purchaser will pay for the timber after considering all of the expenses (LC in the equation above) that are incurred in removing it to the mill. Stumpage, while not explicitly calculated before it is entered into the Spectrum model, it is an inherent part of the above equation [PLV – LC] that is calculated by Spectrum for all potential management prescriptions.

See the above section on "Activities and Outputs" for more detailed information on each of the costs and timber values used in the Spectrum model.

Supplemental Information on Other Model Assumptions

Stage II Suitability Analysis

Each acre classified as suitable for timber harvest was analyzed to determine the costs and benefits for a range or management intensities (36 CFR 219.14(b)). For the purpose of this analysis, the planning area was stratified into categories of land with similar costs and returns according to the Analysis Area Identifiers described above. The stratification also took into account those factors that influence costs and returns such as physical and biological conditions of the site (affecting logging system) and transportation requirements (by VCU).

Stage II analysis is used to identify management intensities of timber production for each category of land that results in the largest amount of discounted net revenues. Stage II analysis provides insight into the overall economic condition of the suitable land base and what types of land are most cost efficient for management. The costs and benefits used for this analysis are described above and include pond log value, the cost of logging, removing, and transporting the timber to the mill as well as the agency-incurred costs of management. This analysis does not account for the utility volume costs or revenues, as the current market conditions do not favor its removal.

Stage II analysis was conducted for all applicable management intensities: Intensive even-aged management with thinning regimes to very small clearcuts and group selection prescriptions (regulation class 3 areas). Table B-3 shows per-acre weighted average net revenue by category. These figures are representative of the highest value of the earliest treatment available to each land type.

The current economic situation in Southeast Alaska creates some confusion in the interpretation of Table B-3. At an initial glance, it may appear there are no economically viable areas for timber harvest. It is important to realize that within each category of land there can be large differences in economics. For instance, the Regulation Class 1 Ketchikan High Volume Class Normal Operability category (-$478/acre) contains a range of economics from acres of short-span helicopter harvest with a large negative net revenue (-$6,917/acre) to acres of shovel harvest in a roaded area with a large per acre net revenue ($3,257/acre). Therefore, a summary of the positive values in each category is also provided in the final two columns of the table. These figures represent the weighted average net value per acre of only those acres that have positive value. Again, some caution in interpretation must be used; the $1,461/acre of Regulation Class 1 Chatham High Volume Class Normal represents 3,600 acres, whereas the Regulation Class 1 Ketchikan High Volume Class Normal Operability ($488/acre) represents nearly 53,000 acres. A complete economic analysis for each Analysis Area is too lengthy for this appendix and is included in the planning record.

Another potentially confusing aspect of these tables occurs due to the decreasing value of more highly stocked stands. An example of this can be seen in the Regulation Class 1 Chatham Normal Operability, where a "Low" stand is valued at -$1,736 and a "High" stand is at -$2,529. Here is a case where on average, the additional cost of removing the volume from the woods is more than the revenues received for that volume. The Chatham is susceptible to this phenomenon likely due to its average distance from the nearest processing mill. The additional cost incurred from shipping more volume from a "High" stand is cumulatively more than the cost of shipping less volume from a "Low" stand. This same relationship generally holds true when comparing Regulation Classes 1 or 2 with Regulation Class 3. In Regulation Class 3, there is generally less volume removed per acre, and therefore the overall costs per acre are lower. Otherwise, the table generally shows lower economic desirability in more expensive harvest systems and lower volumes per acre. Regulation Classes 1 and 2 numbers are predictably similar due to their difference only in allowable clearcut size, green-up intervals, and adjacency constraints, none of which factor into this economic feasibility study.

Table B-3
Discounted Average Net Revenues by Land Category

		Regulation Class 1			Reg. Class 1 - Positive Values Only	
Admin Area	**Volume Class**	**Normal (net$/acre)**	**Difficult (net$/acre)**	**Isolated (net$/acre)**	**Normal (net$/acre)**	**Difficult (net$/acre)**
Chatham	Low	-1,736	-3,242	-4,567	90	
	Medium	-1,842	-5,437	-8,927	585	
	High	-2,529	-7,557	-12,948	1461	
	Young Gr	-184	-5,095	-7,094	873	
Ketchikan	Low	-1,532	-4,474	-6,809	247

	Young Gr	-16	-279	-1,731	112	

The Regulation Class Process

To recognize the varying intensities of timber harvests that may occur on the landscape, the regulation class concept was developed. Regulation Class is a methodology developed to distill the unique combinations of Land Use Designation (LUD), Distance Zone (DZ), Scenic Integrity Objective (SIO), and Visual Absorption Capacity (VAC) into four management categories, or Regulation Classes. These classes group lands that allow similar allowable harvest unit size, visual disturbance, and re-entry times (adjacency). Regulation Classes are numbered 0 to 3, with 0 being ineligible for management. Most of the following discussion is focused on Regulation Classes 1-3.

Land Use Designation (LUD) For each alternative, a unique assignment and map of Land Use Designations was developed. Every Land Use Designation, or LUD, delineates a unique set of standards and guidelines that apply to that area. For each Alternative, up to 19 LUDs were recognized, but only three were allowed to produce timber counted towards Allowable Sale Quantity (ASQ): Scenic Viewshed, Modified Landscape, and Timber Production. These three LUDs were evaluated in the Regulation Class process. See the supplemental Alternative LUD maps and Chapter 3 of the Forest Plan for more specific information on LUDs.

Distance Zone (DZ) The amount of allowable timber harvesting also is affected by distance zone (DZ). Distance zone is the proximity of an area to a view-point. Distance zone varies from Foreground (within a 0.25 mile), Middle Ground, Background, to Not-Seen, which is completely out-of-view from selected viewing points. Again, available treatment intensity is usually greater on lands with more hidden Distance Zones.

Scenic Integrity Objectives (SIO) Scenic Integrity Objectives are a function of LUD and Distance Zone and describe the desired quality of the scenery to be maintained in each classification. The categories include “High,” “Moderate,” “Low,” and “Very Low” objectives. Further description of SIOs is found in the “Scenery” section of Chapter 4 in the Forest Plan. SIOs for each of the LUD/Distance Zone combinations are shown in Table B-4.

Visual Absorption Capability (VAC) The VAC is a measure of an area's ability to "absorb" (make visually less noticeable) ground disturbing activities (i.e., timber harvesting). VAC is simplified to three categories: Low, Interim, and High. VAC is used to define the intensity of management treatments that can be used to maintain each SIO. Generally, areas with greater VAC can sustain a more intensive treatment while still maintaining the desired SIO. Table B-5 shows the management unit size allowed for each SIO/VAC combination.

Tongass landscape architects developed some general timber harvesting guidelines, or proxies, for various VACs, SIOs, and LUDs. Although the exact harvest intensity an area receives is determined during the timber sale layout stages, estimates of allowable disturbance were needed in order to facilitate modeling. Each LUD has a series of adopted SIO and VAC objectives. Associated with these objectives are the estimated allowable disturbance factors. The proxies for each LUD and SIO/VAC setting were grouped by similar harvest method and unit size, cumulative visual disturbance, and height to adjacent stand criteria. Grouping the proxies of similar standards resulted in the creation of four distinct categories. These groups became the four regulation classes used in Spectrum modeling. These groups range from no harvest allowed to large clearcutting with minimal visual concerns. The GIS is then used to provide Spectrum with the regulation class allocations by alternative for each Analysis Area. Table B-6 summarizes the approximate disturbance factors by LUD, Distance Zone, SIO, and VAC.

Table B-4
SIO for Distance Zone/LUD from Scenery Standards and Guidelines

LUD	Foreground	Middle Ground	Background	Not Seen
Scenic Viewshed	Retention	Partial Retention	Partial Retention	Max Modification
Modified Landscape	Partial Retention	Modification	Modification	Max Modification
Timber Production	Modification	Max Modification	Max Modification	Max Modification

Table B-5
Maximum Unit Size based on Visual Absorption Capability

SIO	Low VAC	Interm. VAC	High VAC
Retention	< 2	5-15	15-30
Partial Retention	5-10	15-40	40-60
Modification	15-40	40-60	80-100
Max Modification	50-75	80-100	80-100

R = Retention, PR = Partial Retention, M = Modification, MM= Maximum Modification

The percentages in Table B-6 are rough estimates intended to depict the possible level of disturbance one may encounter when viewing these areas. For modeling purposes, these visual disturbance zones were aggregated into groups with similar standards and economic response (e.g., logging costs). Because the percent of visual disturbance includes all visible terrain, tests had to be conducted to "recalculate" disturbance thresholds since only suitable lands are being modeled. These tests involved a series of iterative mapping exercises where varying levels disturbance factors were applied to the separate groups. The feasibility of the harvest level was then compared to the standards and guidelines and reviewed by Tongass National Forest landscape architects. This work was conducted under the following assumptions:

1. The items in the database (e.g., distance zone, visual absorption capability) were correct,
2. The standards and guidelines are modeled to their limits, and
3. The "viewshed" was a large area (e.g., as viewed from a boat).

This work indicated a need to further review the scenery components of the database but in general the process worked well in terms of modeling the intent of the standards and guidelines. This work resulted in three distinct regulation classes that permit timber harvest activities. The final allocation of regulation classes to the various disturbance zones is shown in Table B-7.

Table B-6
Percent Allowable Visual Disturbance

Land Use Designation	Distance Zone	SIO	Low VAC	Interm VAC	High VAC
Scenic Viewshed	Foreground	R	8	10	10
	Mid. Ground	PR	8	15	20
	Background	PR	20	20	20
	Not Seen	MM	20	20	20
Modified Landscape	Foreground	PR	8	15	20
	Mid. Ground	M	15	20	25
	Background	M	25	25	25
	Not Seen	MM	25	25	25
Timber Production	Foreground	M	15	20	25
	Mid. Ground	MM	50	50	50
	Background	MM	50	50	50
	Not Seen	MM	50	50	50

Table B-7
Regulation Class Allocation

Land Use Designation	Distance Zone	SIO	Low VAC	Intermediate VAC	High VAC
Scenic Viewshed	Foreground	R	3	3	2
	Mid. Ground	PR	3	3	2
	Background	PR	3	2	1
	Not Seen	MM	1	1	1
Modified Landscape	Foreground	PR	3	3	1
	Mid. Ground	M	2	2	1
	Background	M	2	1	1
	Not Seen	MM	1	1	1
Timber Production	Foreground	M	2	2	1
	Mid. Ground	MM	2	1	1
	Background	MM	1	1	1
	Not Seen	MM	1	1	1

R = Retention, PR = Partial Retention, M = Modification, MM= Maximum Modification

There are two main components of scenery constraints applied to the Regulation Classes in each VCU: the total visual disturbance and adjacency considerations. Total visual disturbance is the percent of land within a viewshed (VCU) that is classified as disturbed (Table B-8). Adjacency refers to the amount of time required before a harvest unit can be placed immediately next to an existing harvest unit (often referred to as the "green-up" period). These constraints are shown in Table B-8.

There are several important things to remember regarding the above table:

1. Disturbance percent is applied to suitable lands only, not the entire viewshed.
2. These values are entered into the models as constraints for each VCU.
3. The disturbance and adjacency factors for Regulation Class 3 are based on the use of small patch cutting (less than 2 acres). Optimally, disturbance and adjacency would not be an issue with carefully planned uneven-aged management (i.e., partial stand removal).

Variation by Alternative. Because LUD is one factor in determining Regulation Class, the breakdown of each of the seven alternatives into regulation class was recalculated for each alternative. A GIS map of Regulation Class was developed and used to intersect with the other layers used in Analysis Area development. Regulation Class was then used as an attribute to help define Analysis Areas.

Table B-8
Generalized Visual Constraints
Regulation Class Visual Disturbance Adjacency

Regulation Class	Visual Disturbance	Adjacency
1	40%	20 Years
2	30%	35 Years
3	20%	50 Years

Model Implementation Reduction Factors (MIRF)

To reiterate what was stated in the "Constraints" section (above), the use of MIRF is designed to accommodate for unmapped unsuitable lands that cannot be directly eliminated from the suitable land base but should be. It is known that when harvest activities occur, a certain percentage of the assumed suitable land will be ineligible for management (unsuitable) due to a number of physical, biological, or economic considerations. However, reasonable assumptions can be made to estimate the average amounts of these elements on the ground. Their effect on actual suitable land can be incorporated into the Spectrum model as constraints. Constraints are applied to each old-growth volume strata of each of the six operability harvest systems as well as to young-growth stands. The constraints are implemented by forcing the model to never harvest a certain percentage of the acres in the model. The effect is to control the maximum amount of acres from the "pre-MIRF" suitable land base that are actually harvested. A discussion of these elements and their estimated amounts follows.

MIRF Elements. Each of the nine MIRF subfactors used in the 1997 FEIS (Riparian Habitat was actually divided into two subfactors so there were 10 identified in 1997) was re-evaluated for the 2008 Final EIS. These subfactors are listed below and described in the following paragraphs.

- Land Selections – reduction due to the conveyance of selected lands to the State of Alaska and Native interests
- TTRA Stream Buffers – reduction due to unmapped Class I and II stream buffers
- Non-Commercial Forest – reduction due to volume class mapping errors
- Slope/Soil Hazard – reduction due to unmapped steep slopes
- Cost Efficiency – excludes stands with the lowest economic potential from the suitable base
- Riparian Habitat (Class III streams) – reduction due to unmapped Class III stream buffers
- Karst/Caves – reduction due to upgrading of the karst classification to high vulnerability on some areas
- Deer Habitat – reduction due to implementation of deer habitat standards and guidelines (some 1997 alternatives included these)
- Remaining Standards and Guidelines – reduction due to unmapped raptor and murrelet nests, wolf dens, mountain goat habitat, and habitat linkages

Land Selections. This subfactor estimates the reduction in the suitable land base as a result of conveyance of land to the State of Alaska and Native interests. In 1997, it was assumed that past land selections were representative of future land selections. It was also recognized that the subfactor may be overestimating the suitable lands lost because Native Corporations may select townsites near shore and within the 1,000-foot beach fringe.

In 1997, this subfactor was estimated by determining (with GIS) that there was 638,737 acres of encumbered lands and that 186,980 acres remained to be conveyed. This indicated that 29% of the encumbered lands would be transferred out of Forest Service ownership. Then, the amount of encumbered suitable lands was estimated and 29% was applied to those lands, producing the estimated suitable lands likely to be conveyed. This acreage was divided by the total suitable lands to estimate MIRF for this subfactor, which was rounded to be 2%.

In 2006, the following estimates are made using GIS and other knowledge of lands remaining to be conveyed (see the planning record for calculations):

- Total encumbered lands = 260,487 acres (not including encumbered lands in Misty Fiords)
- Current suitable (Alt 5) encumbered lands = 33,589 acres
- Remaining lands to be conveyed (40,000 State and 65,000 Native interests) = 105,000 acres
- Percent of encumbered to be conveyed (105,000/260,487) = 40%
- 40% of current suitable encumbered lands = 13,436 acres
- Total current suitable = 1,044,587 acres
- MIRF subfactor (13,436/1,044,587) = 1%

Therefore, 1% was used for this MIRF subfactor. This percent was applied to all alternatives.

Tongass Timber Reform Act (TTRA) Stream Buffers. This subfactor estimates the reduction in the suitable land base due to unmapped Class I and II stream buffers. In 1997, it was assumed that the loss of suitable timber was proportional to its occurrence and that streams were randomly distributed across the landscape.

In 1997, this subfactor was estimated using the Forest Service response to the Irland Group report, Chatham data, Central Prince of Wales Island data, and Stikine field reviews. The following TTRA buffer MIRF estimates were made based on each of these studies:

- Irland Study (1992) – 2.50%
- Chatham (1995) – 3.91%
- Central Prince of Wales Island (1995) – 3.62%
- Stikine Field Visit – 2.32%

Based on these estimates, the 1997 MIRF for this subfactor was 2.5%.

For 2006 it was assumed that this percentage is reduced to 2%. This is because of the significant amount of field survey work and the amount of updating of the streams GIS layer that has occurred in the 10 to 15 years since these studies were done.

Non-Commercial Forest. This subfactor estimates the reduction in the suitable land base due to volume class mapping errors. In 1997, it was assumed that reduction in suitable land due to mis-mapping was the same for all three Administration Areas.

In 1997, a statistician at the Pacific Northwest Research Station used the Forest Inventory plot data (1970s) and the revised TIMTYPE volume strata to identify plots designated as high/medium/low volume that actually had less than 8,000 board feet of volume per acre. The 8,000 board feet per acre figure was used as the definition of productive old growth, or POG. This analysis indicated that 2% of the medium volume strata plots and 18% of the low volume strata plots were stocked at less than 8,000 board feet per acre. The reduction for the medium plots was not used because it was judged too small and would overlap with other reduction factors, so 18% MIRF was used for this subfactor only for the low volume strata.

In 2006, 10% MIRF was used for low volume strata for this subfactor. Recent consultation with the Pacific Northwest Research Station statistician concluded that the 18% figure the low volume strata is still reasonable, even with the new inventory data. However, it was decided that there should be recognition of “fall-up” or the determination that areas of Unproductive Forest are misclassified and should actually be POG. It was estimated, based on detailed experience with the inventory data, that 5 to 10% of the Unproductive Forest is POG (> 8,000 board feet/acre). So the following steps were followed:

- The Tongass has 4.22 million acres of Unproductive Forest, 4.95 million acres of POG, and 0.98 million acres of low volume strata POG.
- If 5% of the Unproductive Forest is low volume strata POG, then there are 0.21 million additional acres of low volume strata POG.
- 0.21 million acres represents a 21% increase in the amount of low volume strata.
- If the Forested Muskeg type of Unproductive Forest is not included in Unproductive Forest, then there are 3.15 million acres and 5% of 3.15 million acres is 0.16 million acres. Assuming only half of these acres are actually identified and incorporated into units, this results in 0.08 million acres represents an 8% increase in the amount of low volume strata.

Therefore, being conservative and using only half of the 5% of the “other” Unproductive Forest as “fall-up,” in 2006 an 8% “fall-up” and an 18% fall-down were assumed. Therefore, the MIRF for this subfactor is the net difference, which produces a 10% reduction in low volume strata.

Slope/Soil Hazard. This subfactor estimates the reduction in the suitable land base due to unmapped steep slopes. It represents the additional acreage of steep slopes identified during project implementation that is not already mapped, divided by the mapped suitable acres.

In 1997, this subfactor was based on a draft Baranof MIRF analysis (1996), the Forest Service response to the Irland Group report (1995), Chatham data, Central Prince of Wales Island data, and the Ketchikan cumulative effects contract study (on suitable and fall-down by project area). Based on these sources, the 1997 MIRF for this subfactor was defined as 32% for Chatham and 3.1% for the Stikine and Ketchikan Areas.

For 2006, the slope data that was developed to produce the suitability layer for the new Tongass LSTA was reviewed. This new layer (which removes slopes >72% and includes more detailed information, including LIDAR) already removes many of the steep slopes that were not accounted for in 1997. A GIS query examined the acres in steep slopes that are not in MMI4. This amounted to 6% of the suitable in the Chatham Area and 3% of the suitable in the Ketchikan and Stikine. In addition, there are two other factors that affect the MIRF for this subfactor: First, there is a certain amount of “fall-up” for areas mapped as MMI4 and areas mapped as >72% slope. These positive factors were not considered in the 1997 MIRF. Second, there is a large amount of area removed due to being mapped as Site Index = 1 and it appears that more areas are added back in (due to “fall-up”) than are taken out due to site index. Therefore, for 2006, the Chatham MIRF was reduced for this subfactor to 26% and the Ketchikan and Stikine MIRFs to 1%.

Cost Efficiency. This subfactor excludes the stands with the lowest economic potential from the suitable land base. In 1997, 36 CFR 219.14[c][3] was applied and it was assumed that future economic potential could be estimated using past harvest experience.

In 1997, the subfactor was estimated using the best professional judgment of Bill Wilson and Don Golnick. They assumed that no harvest would be conducted in low volume strata if it was in the Difficult or Isolated Operability Class. In addition, they assumed the same for medium volume strata in the Isolated Operability Class. Therefore, lands with these characteristics had a 100% MIRF subfactor.

In 2006, it was decided that economics should be factored in differently because the Spectrum modeling extends over a 150-year period. It was decided to make the MIRF for this subfactor equal to 25% for Difficult/Low Volume and Isolated/Medium Volume and 50% for Isolated/Low Volume. These subfactors are additive with the other subfactors; therefore, the combined MIRF for these low economic categories ranges from 44 to 79% in Ketchikan, 38 to 73% in the Stikine, and 64 to 99% in the Chatham Area (see attached Excel file).

It should be noted that by design the Spectrum model will tend to harvest the most economically challenging areas only as a means to achieve a desired condition. Even without these subfactors the model is unlikely to schedule these lands for harvest.

Riparian Habitat (Class III Streams). This subfactor estimates the reduction in the suitable land base due to unmapped Class III stream buffers. In 1997, it was assumed that 50% of the Class III streams would need to be buffered and that 50% of the Class III streams were unmapped.

In 1997, the subfactor was estimated to be 14% based on estimating 50% of unmapped Class III stream acreage and then relating it to the suitable. It appears that the amount of suitable used in the calculation was incorrect, making the percentage higher than it should have been.

In 2006, it was decided to be more conservative (although a lower MIRF was estimated). The MIRF for this subfactor was calculated as follows:

- GIS analysis showed 7,557 miles of Class III streams in the development LUDs of the No-Action alternative.
- Since 29% of these development LUDs is suitable forest land, it was estimated that there are 2,191 miles of Class III streams on suitable forest land.
- Assuming all are buffered and the buffers are 100 feet on each side, these stream miles would produce 53,114 acres of buffers.
- Assuming an equal amount will be established in the future: 53,114 divided by 1,044,588 gives a MIRF of 7.6%.
- To be conservative, we rounded this MIRF to 8%.

Karst/Caves. This subfactor estimates the reduction in the suitable land base due to a change in karst classification from low – moderate to high vulnerability. In 1997, it was assumed (based on the professional judgement of J. Baichtal (1996) and others) that 30% of low-moderate lands in Ketchikan should be high vulnerability; similarly, the percentages for the Stikine and Chatham are 10% and 20%.

In 1997, the subfactor was estimated based on professional judgement and GIS queries. For Alternative 11, the MIRF values for this subfactor were: 0.5% for the Chatham Area, 0.3% for the Stikine Area, and 5.9% for the Ketchikan Area.

In 2006, GIS queries were made again, using the new karst rock layer (tkarst06). The MIRF for this subfactor were calculated as follows:

- It was determined there are 100,743 acres of karst rock on suitable lands on the Forest.
- GIS analysis showed these were apportioned among the Administrative Areas as follows: 18.5% (18,637 acres) to the Chatham; 5.2% (5,239 acres) to the Stikine; and 76.3% (76,867 acres) to Ketchikan.
- Applying the 30%, 10%, and 20% factors defined in 1997 for the Administrative Areas produces the following: 3,727 acres of low-moderate should be high vulnerability for the Chatham, 524 acres for the Stikine, and 23,060 acres for the Ketchikan Areas.
- Dividing these by the amount of suitable for these areas (277,016, 354,362, and 413,210, respectively) produces the final MIRFs for this subfactor:
  - Chatham = 1.3%; rounded to 1%
  - Stikine = 0.1%; rounded to 0%
  - Ketchikan = 5.6%; rounded to 6%

Deer Habitat. This subfactor estimates the reduction in the suitable land base due to implementation of the deer standards and guidelines. In 1997, these applied to the high and medium volume strata for Alternatives 3, 4, 5, and 6 of the 1997 Final EIS.

In 2006, this subfactor is not used, because none of the 2006 alternatives include these deer habitat standards and guidelines.

Remaining Standards and Guidelines. This subfactor estimates the reduction in the suitable land base due to unmapped eagle/osprey nests, goshawk nests, murrelet nests, wolf dens, goat habitat, and 600-foot habitat linkages. In 1997, this subfactor was estimated at 1% based on the best professional judgement of Bill Wilson and Don Golnick.

In 2006, it was decided to maintain the MIRF of 1% for this subfactor.

Overall Results. The sum of these subfactors produces the overall MIRF for each category (Administrative Area, volume strata, operability class, alternative). To date, we have identified one MIRF for all alternatives. Specific calculated MIRF values are in the planning record. The range of MIRFs (varying with operability class) for the different volume strata and Administrative Areas are as follows:

	Low Volume	Medium Volume	High Volume
Chatham	49% – 99%	39% – 64%	39%
Stikine	23% – 73%	13% – 38%	13%
Ketchikan	29% – 79%	19% – 44%	19%

Estimation of Past and Future Harvest and Road Construction for Effects Analysis

The quantification of the direct, indirect, and cumulative effects of the alternatives on fish, wildlife, plants, and other resources was based heavily on the estimation of past and future harvest of old growth and young growth and the amount of road construction. These tasks were conducted for both National Forest System (NFS) and non-NFS lands. This section describes the process followed and the major assumptions.

Estimation of Past and Future Harvest

The estimation of the direct, indirect, and cumulative effects of the alternatives on POG habitats and the fish, wildlife, and plants that use these habitats required three major steps. First, it was necessary to assemble the inventory of existing vegetation on both NFS and non-NFS lands. The second step was the estimation of the original POG on NFS and non-NFS lands and the classification of this original POG into POG types for the purpose of evaluating the level of disproportionate past harvest. The third step was the estimation of future harvest and the amount of POG in various POG categories that would be remaining after future harvest on NFS lands under each alternative, and for all lands combined, including factors for harvest of future harvest on non-NFS lands.

Vegetation Inventory

For NFS lands, the existing vegetation information from the Tongass Geographic Information System (GIS) library was used. Specifically, the recently developed Size Density Model (SDM) (see Affected Environment in the *Biodiversity* section) was used for the classification of existing vegetation on the Tongass. Using this model, POG is defined by seven old-growth types: SD67, SD5N, SD5S, SD5H, SD4N, SD4S, and SD4H. Young growth is defined by six types, depending on the approximate age and origin of the stand; natural young growth (e.g., young growth originating from blowdown) is divided into three types (S1, S2, and S3) and young growth that originated from timber harvest is classified into three types (HS1, HS2, and HS3).

For non-NFS lands, a number of sources of information were used to produce the most updated and accurate mapping available for non-NFS lands in Southeast Alaska. These sources included:

- Sealaska Regional Corporation provided recently updated GIS layers for vegetation and harvest on their lands throughout Southeast Alaska; these layers were used for mapping all Sealaska lands.
- The State of Alaska provided GIS layers for harvesting on state lands in Southeast Alaska. These layers were used for most state lands.
- Audubon Alaska and The Nature Conservancy recently completed a conservation assessment for Southeast Alaska (Albert and Schoen 2007) that included the development of a reasonably accurate vegetation map of the entire region based on Tongass GIS vegetation data (SDM mapping), augmented with timber inventory data from Haines State Forest and with classified Landsat Multi-spectral Scanner (MSS) imagery from the Interim Landcover Mapping Program of the U.S. Geological Survey, and 1997 aerial photography. This mapping was used for most of the remainder of Southeast Alaska.
- Forest Service orthophotography and aerial photography was interpreted in some areas to fill in gaps in the above layers.

Based on all of the above information, a Catalogue of Past Harvest for all of Southeast Alaska was developed that itemizes the acres harvested for each land ownership category, landowner, and biogeographic province, and breaks this harvest down by approximate decade, where the decade of harvest is known or can be reasonably estimated. In addition to the spatial information described above, statistics on the implementation of the Alaska Forest Resources and Practices Act and information on State timber sales in Southeast Alaska were collected from the Alaska Department of Natural Resources, Division of Forestry. This information is presented in Appendix E.

Original POG by Category

Next, the original POG was estimated on NFS and non-NFS lands in each biogeographic province and ecological subsection by category. This was done for the purpose of evaluating the level of disproportionate past harvest.

Original POG is defined in this EIS as the POG that existed, outside of the developed areas associated with towns, prior to all mapped timber harvest. Therefore, all young growth originating from timber harvest (mapped as HS1, HS2, and HS3 on NFS lands) was assumed to be original POG. Natural young growth (mapped as S1, S2, and S3 on NFS lands) was assumed to be in a steady state of succession and replacement; therefore, it was not assumed to be original POG. On the Tongass, about 300 acres of young growth were mapped as having been harvested in the 1700s and 1800s and about 16,000 acres are from the first half of the 1900s. The vast majority (about 438,000 acres on the Tongass) of the harvest occurred since 1950.

In addition to total POG (represented by the seven SDM types), two other categories of POG were used to represent the larger tree types: high-volume POG, which includes the three types with the largest trees (SD5S, SD5N, SD67), and large-tree POG, which is defined as SD67 by itself. To estimate original high volume- and large-tree POG, an estimate was first made of the percentage of past harvest in these categories using timber type mapping from the mid-1980s. The archived tim86 GIS layer from the Tongass GIS library was used and lands that had been harvested since this mapping was done were examined. For NFS lands, these areas were divided into older harvests done prior to the TTRA and harvests after the Act was implemented.

The following compositions of harvest were determined for NFS and non-NFS lands:

- For NFS lands, prior harvest was estimated to have been 29 percent large-tree POG and 64 percent high-volume POG.
- For non-NFS lands, prior harvest was estimated to have been 37 percent large-tree POG and 62 percent high-volume POG.

Future Harvest

Future harvest on NFS lands was estimated based on the acreage of POG scheduled for harvest by the Spectrum model under each alternative assuming the maximum harvest allowed by the ASQ is harvested each decade. The estimate assumes all scheduled suitable POG is harvested (calculated by subtracting alternative-specific reduction factors for MIRF and scheduling from the mapped suitable acreage under each alternative [see the *Timber* section]). Factors are applied separately to each biogeographic province and ecological subsection to develop province- and subsection-specific acreages.

The estimation of future harvest on non-NFS lands was made by examining the amount of POG remaining on these lands and making reasonable assumptions regarding the percentage of that POG that would be harvested in the future. Estimates were conservatively high, in general.

Estimation of Past and Future Road Construction

The estimation of the direct, indirect, and cumulative effects of the alternatives associated with road construction required two major steps. First, it was necessary to assemble the inventory of existing roads on both NFS and non-NFS lands. The second step was the estimation of future road development for NFS lands under each alternative, and for all lands combined, including factors for future road development on non-NFS lands.

Road Inventory

For NFS lands, the existing road information from the Tongass GIS library was used. The infra roads layer was used for the inventory of system roads and the definition of maintenance levels to determine whether they were open or closed. The allroads layer was used to estimate additional unauthorized roads. For non-NFS lands, existing roads were inventoried using the following sources:

- Tongass GIS library layers contain many roads on non-NFS lands.
- Sealaska Regional Native Corporation provided mapping of roads on Sealaska lands.
- The State of Alaska provided GIS layers for roads on many non-NFS lands in Southeast Alaska.
- Other available GIS layers (e.g., ESRI's StreetMap) was used for urban and rural areas around towns and settlements.
- The sources above were supplemented by orthophoto and aerial photograph interpretation to "fill in holes."

Future Road Construction

Future road construction on NFS lands was estimated based on the recently completed logging system and transportation analysis (LSTA) for the Tongass. In areas that the LSTA did not cover, future roads were extrapolated based on the road miles per harvest acreage in the portions of each Value Comparison Unit (VCU) or Wildlife Analysis Area (WAA) that were covered by the LSTA. Projections were made for each VCU and WAA and under each alternative, so that road densities could be calculated for each of these land divisions.

On non-NFS lands, future increases in road density were projected after examining existing road densities and making reasonable assumptions regarding the additional road density that would be developed in the future. Estimates were conservatively high, in general. All non-NFS roads were assumed to be open roads.

Deer Model Assumptions and Application

The TLMP or DeGayner Deer Model was used in the EIS to (1) evaluate reductions in winter habitat capability under each alternative, as indicated by changes in the DeGayner Deer Model habitat suitability index (HSI) scores, (2) estimate the percentage of high value deer winter range that could be harvested under each alternative, and 3) estimate the number of WAAs across the Tongass that exceed the 18 deer per square mile index in the wolf standards and guidelines. Changes in winter habitat capability and harvest of high-value winter range were based on projected 1954 (point at which large-scale timber harvest began) conditions, to be consistent with past analyses done at the Forest planning level. Analyses were run at the WAA level, as this is the land division used by the ADF&G for deer inventories and planning. A cross-walk was developed to reclassify the new Forest-wide vegetation model (the SDM) into the deer model vegetation categories (high, medium, low volume old-growth). High-volume stands included SDM vegetation categories SD5N, SD5S, and SD67; medium volume stands include SD4N, SD4S, and SD5H; and low volume stands include SD4H. HSI scores from this model range from 0 to 1.3 but were standardized to range from 0 to 1.0 by dividing all values by 1.3, because outputs from such models represent a range from 0 to 100 percent habitat suitability, with higher values indicating higher habitat capability. Greater details are documented in the project planning record.

To estimate 1954 habitat suitability, it was necessary to "grow back" the vegetation in previously harvested units. Previously harvested units were assumed to have been stands of POG. The variable for volume class (VolClass) in the Existing Veg layer, which exists for most stands that have recently been harvested, was used as an indicator of their 1954 VolStratum categories. Stands with an Existing Veg VolClass of 4 or 5 were assumed to have been medium volume POG in 1954, following the assumption that few low VolStrata stands were harvested; stands with a VolClass of Null, 3, 6, or 7 were assumed to have been high VolStratum POG. VolStratum 6 and 7 were obviously in high VolStratum and it was assumed that the remainder of the stands that were harvested many years ago were in the high VolStratum also. All stands with a date of origin prior to 1954 were not modified.

Future habitat suitability was based on maximum timber harvest after full implementation of the Forest Plan under each alternative. It was assumed that 25 percent of the harvestable acreage would be in the stand initiation stage (I) and 75 percent of harvestable acreage would be in the stem exclusion stage (E) of stand development after full implementation. In addition, the MIRF, or the percent of the mapped suitable acres not actually harvested due to factors identified during implementation (e.g., karst, unstable slopes and other issues that preclude harvest during timber sale layout), and a scheduling factor was taken into account as they are for the timber volume estimation, the Spectrum ASQ modeling, and other future harvest and road construction estimation.

Accordingly, future WAA-level HSI scores were based on a weighted average of three scenarios, or model runs, which assumes that all harvestable lands are harvested. This approach produces an unbiased estimate of future HSI scores under the assumption that 25% of all suitable forest land is in the I stage, 75% is in the E stage, the remaining harvested young growth (unsuitable) is in the E stage, and all old growth and natural young growth remains the same. No-Harvest Scenario weights account for the area represented by MIRF and scheduling and which is not harvested.

To estimate the percentage of 1954 winter range habitat capability that currently remains, and would remain under each alternative after full implementation of the Forest Plan, the1954 HSI score was divided by the current and future HSI score for each WAA, respectively. This illustrates the cumulative effect of timber harvest on estimated deer habitat capability, from the beginning of large-scale timber harvest on NFS lands in 1954 to the present and to the year 2105.

To take into account effects on deer across the Tongass inhabiting areas that vary naturally in their habitat quality, high quality habitat was defined as the quartile of the current land base with the highest HSI scores within each WAA. This was defined by using the following process:

- Sorting HSI scores within each WAA from highest to lowest by polygon;
- Filtering out all polygons with HSI scores = 0 (this area was not included when identifying the area percentages);
- Identifying the polygons that are in the highest 25% based on the WAA acreage, by accumulating the acreages starting with the polygons with the highest HSI scores and working down until 25% of the area was included; and
- Determining the percentage of these acres (which represent the highest quality deer winter range within each WAA) that are harvested under each alternative.

Deer per square mile were calculated to develop an index of the effects of the alternatives on the wolf standard and guideline that deals with deer habitat capability. For this analysis, habitat capability in terms of deer density was calculated by assuming a density of 100 deer per square mile for an HSI of 1.0. Only WAAs where wolves potentially occur (GMUs 1, 2, 3, and 5) were included and WAAs with naturally very low deer densities (WAAs 4302-4607) were excluded from the analysis.

APPENDIX C
POTENTIAL LAND ADJUSTMENTS

Appendix C

Potential Land Adjustments

CONTENTS

LIST OF TABLES

Appendix C
Potential Land Adjustments

Introduction

This appendix addresses certain types of land ownership adjustments involving Tongass National Forest lands that could potentially occur during the period of the Forest Plan Amendment. Adjustment of land ownership within the Tongass boundaries can occur through Congressionally-mandated conveyances, exchanges, and acquisitions or through Forest Service administrative activities. The latter two types of adjustments typically involve small acreages and specific, localized property circumstances, and have little impact on management of the Tongass. Land conveyance processes and land exchanges can involve larger acreages and can be relatively wide-ranging in geographic scope. Because these types of adjustments could have more substantial implications for Forest management, this appendix provides more detailed information about specific potential actions that have been proposed by parties other than the Forest Service in recent years. The discussion of the possible ramifications of potential conveyances or exchanges is an overview and is intended for informational purposes only. It does not represent a National Environmental Policy Act (NEPA)-type analysis of the potential environmental impacts of such actions. If the Forest Service were to propose such a land adjustment action or accept for review a proposal from another entity, the Forest Service would evaluate the proposal under NEPA and standard Forest Service processes for land adjustments.

Legislated Alaska Conveyances

Land ownership status within the Tongass is complicated by several ongoing Alaska land conveyances created under various federal legislation (USDA Forest Service 2003b). The Alaska Native Allotment Act of 1906 provided for Native individuals who had occupied lands prior to their designation as National Forest to apply for conveyance of up to 160 acres, under conditions prescribed by the Act and federal regulations. As of August 2006, approximately 4,500 acres in 44 Native allotments had been conveyed, with an additional 3,500 acres pending adjudication by the Bureau of Land Management (BLM).

The 1958 Alaska Statehood Act authorized the State of Alaska to select 400,000 acres of vacant and unappropriated land from within the Tongass and Chugach National Forests in Alaska, to further the development and expansion of Alaskan communities. To date, under this provision of the Statehood Act, the state has received title to approximately 258,600 acres located in the Tongass National Forest. Approximately 37,400 acres remain to be conveyed to the state from the Chugach and Tongass National Forests.

The Alaska Native Claims Settlement Act (ANCSA) established processes for transfer of federal land to Alaska Native village corporations and regional corporations, and to Native individuals. ANCSA provided for the conveyance of 23,040 acres of surface estate lands (a full township, 36 square miles) to each of the 10 Native village corporations and 2 urban corporations located in Southeast Alaska. ANCSA provided that the subsurface estate under the village and urban corporation land would be conveyed to the Native regional corporation. ANCSA also included other provisions addressing land conveyances to Native regional corporations. Under Section 12c of ANCSA, 11 regional corporations were to share in the selection of 16 million acres. Section 14(h)(8) set aside a pool of 2 million acres to be transferred to the Native regional corporations in the State after certain other conveyances are completed. After the specified conveyances have been implemented, the remaining land in the pool will be divided among the regional corporations based on population, with approximately 22 percent of the balance going to Sealaska Corporation, the regional corporation for Southeast Alaska. Finally, ANCSA provided for selection and transfer of up to 160 acres to Native individuals who had occupied that land as a primary place of residence on August 31, 1971.

To date, approximately 571,000 acres within the Tongass have been conveyed under ANCSA. Each of the 10 Native village corporations and 2 urban corporations in Southeast Alaska has selected its authorized acreage; virtually all of that land has been conveyed, amounting to a total of approximately 279,000 acres. Approximately 292,000 acres have been conveyed to date to Sealaska Corporation, in addition to the subsurface estate under the lands owned by the village and urban corporations. Sealaska has selected about 171,000 additional acres. It is expected that approximately 64,000 acres of these lands will be conveyed to Sealaska.

Potential Future Conveyances

The major Alaska land conveyances described above (those occurring under the Alaska Statehood Act and ANCSA) have been authorized by Acts of Congress and implemented through additional legislation and regulations. In recent years there have been a number of other formal and informal proposals that, if authorized, might result in the transfer of Tongass National Forest System (NFS) lands out of federal ownership. Information currently available to the Forest Service about these conveyance proposals is provided below. For each proposal, the text includes background information, a description of the conveyance proposal, and a discussion of the potential implications for land ownership and management of the Tongass. Because the proposed legislation for the respective conveyances does not generally specify where land selections would be made, it is not possible at this time to identify the types of Tongass lands and resources that would likely be affected by the proposals. Consequently, the discussion of forest management implications for the potential conveyances is necessarily quite general.

Southeast Alaska Native Land Entitlement Finalization Act

A proposal was identified in the Draft EIS entitled Sealaska Proposed Comprehensive Tongass-wide Land Exchange. Since the Draft EIS was published, the potential land exchange has evolved into a legislative proposal entitled Southeast Alaska Native Land Entitlement Finalization Act, which was subsequently introduced into Congress as H.R. 3560. This bill, as introduced, more closely resembles a conveyance rather than a land exchange as earlier described. The text describing the original proposal has been maintained under the Potential Land Exchange section of this appendix so readers can compare the current proposal to the original proposal identified in the Draft EIS.

H.R. 3560 is to provide for the completion of certain land selections under ANCSA, and for other reasons. H.R. 3560 defines its purpose as the vehicle to redress the inequitable treatment of the regional corporation for Southeast Alaska by allowing Sealaska to select its remaining entitlement under section 14 of the ANCSA (43 U.S.C.1613). These selections are to come from designated Federal land in Southeast Alaska, outside the ten Southeast Alaska village withdrawal areas. In general, H.R. 3560 authorizes Sealaska to select and receive conveyance of its remaining land entitlement from three categories including economic development lands; sites with sacred, cultural, traditional, or historic significance; and Native enterprise sites.

Proposal and Current Status

H.R. 3560 was referred to the House Committee on Natural Resources, U.S. House of Representatives, in Washington D.C. on September 18, 2007. A hearing was held by the same Committee on November 14, 2007. Testimony was presented by officials from the Departments of the Interior and Agriculture for the Executive branch, along with representatives of the Sealaska Corporation and Southeast Alaska Conservation Council. At this time no additional hearings or committee assignments have been identified and it is not clear whether or not this proposal will move further through the legislative process.

The goal of the H.R. 3560 is to finalize Sealaska's entitlement equitably; secure ownership of places of sacred, cultural, traditional, and historic importance; maintain its existing resource development and management operations; and continue economic opportunities for the Native people in Southeast Alaska. While not clearly defined in the Act, those lands identified as entitlement are assumed to be similar to those described in the Potential Land Exchange section of this appendix. For brevity, this section will not repeat the information described in that section. Maps (Sealaska ANSCA Land Entitlement

Rationalization Pool, dated May 17, 2007) have been made available that define the locations of the potential land acquisitions, which further refine what was presented in the Draft EIS. Upon completion of the land conveyance from the Tongass to Sealaska, all encumbrances (327,000 acres according to the Bill) currently held by the regional corporation would be removed.

Two new items presented by H.R. 3560, were not addressed in the Draft EIS. These include sites with sacred, cultural, traditional, or historic significance (sacred sites) and Native enterprise sites. The sacred sites encompass no more than 2,400 acres of known locations (identified on maps entitled "Places of Sacred, Cultural, Traditional, and Historic Significance, dated May 17, 2007" and "Traditional and Customary Trade and Migration Routes, dated May 17, 2007"). An additional 1,200 acres is set aside and may be used by Sealaska to acquire new discoveries. The known sites are depicted across the extent of the Tongass National Forest and prohibit commercial timber harvest; shall not be subject to additional covenants; and provide for varying uses of the sites by Sealaska.

Native enterprise sites encompass no more than 5,000 acres and are identified on a map entitled "Native Enterprise Sites dated May 17, 2007." These sites are identified across the extent of the Tongass National Forest and prohibit commercial timber harvest; shall not be subject to restrictive covenants; provide for access from the site to NFS lands 15 miles away from the exterior boundary of the site; and provide for varying uses by Sealaska.

Forest Management Implications

The Forest Service conducted preliminary analysis of the economic development lands in the Draft EIS. Based on how these lands are described in H.R. 3560, it is likely that the effects of the Act would be similar to what is presented for the Sealaska Proposed Comprehensive Tongass-wide Land Exchange in the Potential Land Exchange section of this appendix. Rather than repeat that analysis here, readers are directed to that text for reference.

Sites with sacred, cultural, traditional, or historic significance as well as Native enterprise sites could potentially affect management of many resources and issues on public lands, including subsistence, recreation, wildlife and fish, timber (including second growth), karst, travel management, and heritage resources. These potential effects are difficult to determine from the proposed legislation due to the vagueness of its language. More information, than what can be derived from the bill and testimony, would be necessary in order to adequately address this issue.

From the review the Forest Service conducted in the Draft EIS only on economic development lands, it was determined that implementation of the Sealaska proposal would require a Forest Plan Revision based on the magnitude of the changes in land use designations. With the addition of the sacred and Native enterprise sites, this determination is still warranted as a result of net losses in the Conservation Strategy, the lack of ability in making up key lands associated with the old-growth reserves, effects on the Allowable Sale Quantity, and impacts associated with other existing uses. Additionally, the lands to be exchanged to the federal government generally do not have existing road systems, and costs for developing roads on these lands would likely constrain the ability to supply timber economically. The combined impacts on the availability of timber from the Tongass could have a significant adverse effect on the supply of timber to mills on Prince of Wales Island and surrounding areas.

Table C-1 (at the end of this appendix) has been updated to reflect the acreages included in the legislative proposal and assumes like acreages for the economic development lands as described in the Draft EIS. It indicates the acreage of the NFS lands that could be transferred to Sealaska via the entitlement and conveyance components of the proposal, and the acreages of the current Sealaska lands that could be conveyed to the U.S. This table displays the acreages of the entire pool of parcels. The actual acreage conveyed would likely be less than listed.

Additionally, the U.S. Fish and Wildlife Service recently published a determination not warranting the listing of the Queen Charlotte Goshawk (Accipitier gentilis laingi) in Alaska (Federal Register on November 8, 2007). This determination was made, in part, based on the habitat protection measures on federal lands. Should the proposed legislation be implemented a high probability exists that this determination would be revisited, given the current harvest level that has taken place on Prince of Wales Island, where the legislation would give emphasis to lands being acquired by Sealaska.

University of Alaska Lands

The following discussion is based on information obtained from the University of Alaska and Senate Bill 293.

By separate acts passed in 1915 and 1929, Congress granted approximately 360,000 acres of surveyed land to the University of Alaska to be used to generate revenue to support the University's educational mission (University of Alaska 2005). Only about 100,000 acres had been surveyed and conveyed to the University by the time of statehood in 1959, and the Statehood Act extinguished the University's right to receive the balance of its federal land grants. At that time the State of Alaska also took on management responsibility for the University lands, and allowed several municipalities to select University grant lands for their municipal entitlements without compensating the University. Through multiple settlements of lawsuits filed by the University, the University subsequently gained title to additional lands and timber harvest rights. The University of Alaska now owns and manages approximately 183,000 acres of land, of which approximately 170,000 acres are managed for investment purposes. Because the University received only a portion of the acreage total granted it by Congress, and that figure was smaller than the university land grant for virtually all other states, the University has sought additional grant lands through proposed state and federal legislation.

Proposal and Current Status

Under the terms of Senate Bill 293, introduced in Congress on February 3, 2005, the University of Alaska will be allowed to select up to an additional 250,000 acres of federal land that would be managed to provide income for the university system. If enacted, the university would not be allowed to select lands within a federal conservation system area (e.g., a national park or a wilderness area) or Tongass NFS lands other than those within development Land Use Designations (LUDs), and their selections would be limited to areas of second-growth timber where timber harvest occurred after January 1, 1952. Senate Bill 293 was not passed by Congress. As of September 2007, the bill has not been re-introduced.

Forest Management Implications

The proposal to allow conveyance of federal lands to the state to provide income to support the University of Alaska exists in concept only at this time. The Forest Service is aware of no maps indicating areas of interest for selection for such purpose, or statements from policy makers identifying areas that might be of interest. Therefore, it is not possible to determine specifically how enactment of such a conveyance process might affect management of the Tongass.

Based on the purpose of the University of Alaska Lands Bill, however, it is possible to identify the broad outlines of possible implications for the Forest. Because the purpose of the program is to generate income, lands with relatively high timber production capability and accessibility are a logical focus of land selection under such an act. Areas known or suspected to have high mineral resource potential will also be of interest. While some areas of the Chugach National Forest and some lands under the jurisdiction of the BLM will also be of interest, it is reasonable to assume that a substantial portion of any lands selected under such a conveyance program will be located on the Tongass.

Under the current Forest Plan, there are approximately 3.6 million acres within development LUDs and nominally available for selection, based on the language of Senate Bill 293. The Biodiversity section of this EIS indicates approximately 453,000 acres of the Tongass are second growth resulting from timber harvest (about 234,000 additional acres are in natural young growth). About 240,000 of these acres are in the 0-70 year age category and are on lands suitable for timber harvest. Therefore, this latter figure represents the lands that could be taken as the approximate area eligible for selection. Therefore, it is conceivable that land selection for the University of Alaska could absorb essentially all second-growth land in development LUDs on the Tongass. While this is possible, the Forest Service does not consider that to be a realistic possibility, given the availability of large areas of federal lands with income-generating potential elsewhere in the state.

If the University of Alaska Lands Bill is enacted, it is evident that any lands within the Tongass selected by the University would be productive timber lands currently supporting second-growth timber of varying ages. Because little, if any, of that timber is ready for harvest relatively soon, there would likely be minimal direct effect on near-term sales and harvest volumes for the Tongass. Nevertheless, removal of productive forest land from the development LUD land base would necessarily cause a commensurate reduction in the ASQ for the Forest, and therefore indirectly result in reduced harvest volumes from the Tongass in the relatively near term. Conversely, it can reasonably be assumed that any Tongass lands selected by the University under such a program will be open for timber harvest by the University and will provide a supply of wood as soon as that is economically viable. Therefore, over the long term it appears likely that the total harvest volume would not be much different with enactment of the University lands legislation, although the mix of sources would change somewhat. Timber from University lands would presumably be available for export, however, in which case the supply of wood to processors in Southeast Alaska could be reduced somewhat.

Unrecognized Southeast Alaska Native Communities

Under the Alaska Native Claims Settlement Act (ANCSA), corporations representing Native residents of 10 Southeast Alaska communities were each allowed to select 23,040 acres of surface estate for conveyance from the U.S. to those village corporations. ANCSA also provided the same conveyance rights to two Native urban corporations in Southeast Alaska. Native residents of Haines, Ketchikan, Petersburg, Tenakee Springs, and Wrangell were not addressed in those ANCSA provisions presumably because they did not meet the eligibility requirements. For a number of years there have been legislative proposals to extend land conveyance rights to the Native residents of these five communities to place them on an equal footing with other Southeast Alaska communities.

Proposal and Current Status

The Unrecognized Southeast Alaska Native Communities Recognition and Compensation Act (Senate Bill 1746), introduced most recently on June 29, 2007, proposes to allow Alaska Native residents of Haines, Ketchikan, Petersburg, Tenakee Springs, and Wrangell to organize as five Urban Corporations and to each receive 23,040 acres of surface estate lands and other compensation. Sealaska Corporation would receive the subsurface estate to these lands. The language in the bill does not identify the specific areas that would be available for selection and conveyance.

Forest Management Implications

If enacted, Senate Bill 1746 would presumably result in the transfer of up to 115,200 acres of current NFS lands out of federal ownership. Such an action would represent a reduction of approximately 0.7 percent in the total Forest land base. Given the limited existing information about how the proposal might be implemented, it is difficult to speculate as to which types and acreages of NFS lands would be affected. It is also unknown if selections would be allowed within congressionally designated areas such as Wilderness and LUD II areas. If it is assumed that selections would occur from available lands in areas close to the respective communities, selections under such a program could affect LUDs as follows:

Haines – Semi-Remote Recreation and Remote Recreation, with some Modified Landscape on either side of Lynn Canal

Ketchikan – Semi-Remote Recreation, Scenic Viewshed and Timber Production

Petersburg – Modified Landscape, Scenic Viewshed, Timber Production and Old-Growth Habitat

Tenakee Springs – Modified Landscape and Timber Production

Wrangell – Modified Landscape, Scenic Viewshed, Timber Production and Old-Growth Habitat

Based on the distribution of Tongass lands near the subject communities, it appears that Native selections under such a program could be concentrated within moderate development and intensive development LUDs. Alternatively, newly-formed village corporations might choose to select productive timberlands, to maximize the revenue potential from their lands. In either case, it appears likely that a large majority of the total selected acreage would occur in development LUDs. Consequently, a conveyance program such as outlined in Senate Bill 1746 would likely result in forest management implications similar to those discussed above for the proposed University of Alaska conveyances. Based on the respective potential acreage figures (up to approximately 250,000 acres vs. about 115,000 acres), passage of Senate Bill 1746 or similar legislation could affect approximately half as much land on the Tongass as the University land proposal. Adoption of such a proposal would likely result in a minor reduction in the land base of suitable timber and a small corresponding decrease in the ASQ.

Alaska Native Veterans

The 1906 Native Allotment Act established a conveyance process under which individual Alaska Natives could select and receive title to up to a 160-acre parcel of vacant, unappropriated, and unreserved nonmineral federal land. Allotments may be made in national forests if founded on occupancy and use of the land prior to the establishment of the forest. In 1971, ANCSA repealed the Native Allotment Act and extinguished this right for Alaska Natives to claim allotments. The 1998 Alaska Native Veterans Allotment Act (Public Law 105-276) amended ANCSA to provide Alaska Native veterans another opportunity to apply for a Native allotment of up to 160 acres of land. This act was intended to compensate for the fact that Natives serving in Vietnam may not have been able to apply for their allotments prior to closure of the allotment program. This situation applies to approximately 2,800 Alaska Natives who served in the military during the Vietnam conflict. The 1998 legislation contained several provisions regarding federal land status, prior use of the claimed land and eligible military service dates that may be viewed by some as barriers to Native veterans obtaining their allotments.

Proposal and Current Status

The Alaska Native Veterans Land Allotment Equity Act, introduced most recently on August 2, 2007, as House Bill 3350, proposes to redress certain obstacles created by the 1998 Alaska Native Veterans Allotment Act. The Bill allows Alaska Natives who served in the military between August 5, 1964 and May 7, 1975 (the starting and ending dates of the entire Vietnam conflict) to each claim 160 acres of vacant federal land. Unlike the 1998 legislation, Alaska Natives filing under this program would not have to demonstrate substantially continuous use or occupancy of the subject land for at least five years that is potentially exclusive of others. Based on the estimated number of eligible Alaska Natives and the allotment size, this legislation could, if passed, result in the conveyance of up to approximately 448,000 acres of federal land in Alaska.

As of November 2006, the current Congress had not taken action on Senate Bill 2000 and passage is not likely to occur before this Congress adjourns. Future action would require reintroduction of the bill in the next Congress, which will convene in 2007.

Forest Management Implications

- The Forest Service is not aware of any information indicating how much Tongass land might be selected for Native allotments if this legislation is passed. It is unknown how many of the approximately 2,800 Alaska Native Vietnam veterans addressed by Senate Bill 2000 would actually select and claim land for allotments. In addition, many of those veterans no doubt live elsewhere in the state and would be inclined to select allotments in regions other than Southeast Alaska. Alaska population statistics indicate that Native Alaskans living in Southeast Alaska comprise about 12 percent of the total statewide Native population (Alaska Department of Labor and Workforce Development 2006). If Alaska Native Vietnam veterans are distributed geographically in the same proportion and selected allotment lands within their home region, the maximum area of Tongass lands potentially subject to selection under such an allotment program would appear to be in the range of 50,000 to 55,000 acres.

- It is not known what type of lands Alaska Native Vietnam veterans would be inclined to select under such an allotment program. Because the individual parcels would be small, many claimants might be inclined to select parcels that would be desirable for homesites or locations for hunting and fishing camps. Alternatively, some might select lands with income potential from timber resources. An allotment program such as proposed in House Bill 3350 could have implications similar to those described above for the proposed Unrecognized Southeast Alaska Native Communities Recognition and Compensation Act, including a reduction in the suitable timber land base and ASQ on the Tongass. To the extent such effects would occur, they would be considerably less extensive based on the respective acreages involves, and would be minor from a Forest-wide perspective. Because an Alaska Native Vietnam veteran allotment program could result in a relatively large number of small, scattered private inholdings around the Tongass, perhaps a more important forest management effect would be to complicate land ownership administration by the Forest Service in areas where allotments were selected.

Alaska State Forest

The Alaska Department of Natural Resources, Division of Forestry manages extensive areas of current State-owned lands that are forested. Those lands include two designated state forests, the Haines State Forest and the Tanana Valley State Forest, which together comprise over 2 million acres and about 2 percent of all State-owned land (Alaska Department of Natural Resources 2006). The two state forests are managed to provide a sustained yield of many resources, primarily timber, while allowing other beneficial uses of the public land and resources. The state forests also provide fish and wildlife habitat, clean water, opportunities for recreation and tourism, and minerals. The Haines State Forest contains approximately 286,000 acres of land north of Haines in Southeast Alaska, generally in the Chilkat River watershed and surrounding the Chilkat Bald Eagle Preserve.

Various State of Alaska officials or interests have at times advocated for the establishment of an additional Alaska State Forest, to be managed to provide income for state government programs. A new state forest conceivably could be created through state legislation creating a new management unit on existing state-owned lands, or through federal legislation establishing a new conveyance process to transfer additional federal lands to state ownership for management as a state forest. If such a proposal were ever implemented through federal legislation, it would presumably include conveyance of existing Tongass and/or Chugach National Forest lands with timber production capability to the State of Alaska.

Proposal and Current Status

- The Forest Service is aware of no formal, public proposal to create an Alaska State Forest. To date, no federal legislation to implement such a proposal has been introduced in Congress, and State documents do not indicate the size and location envisioned for a state forest. The Forest Service is aware of public discussion of one concept for such a management unit, which involved a 2-million-acre area on or near Prince of Wales Island. Creation of a state forest in such a location would require transfer of extensive areas of current Tongass NFS lands to the state. Because there has been no formal proposal or action on a proposal, establishment of an Alaska State Forest in Southeast Alaska should be considered a speculative possibility.

Forest Management Implications

With respect to the types of potential changes, the implications for future management of the Tongass from establishment of a new, large-scale state forest would be similar to those described for the proposed University of Alaska Lands bill, although the affected area would likely be much larger. Consistent with Alaska State Senate Bill 149 that was signed into law on August 8, 2003; a new Alaska state forest would presumably be managed for timber resources while allowing for other beneficial uses of public land and resources. Therefore, future management and human uses of Tongass lands conveyed to the state under such a proposal might be managed more intensively for timber production than under current management and uses. The state would likely be inclined to select productive timber lands for inclusion in a new state forest, and would emphasize timber production as a primary uses of those lands. Based on current Alaska state forest management policies, the new state forest lands would also presumably continue to support other resource values such as water, fish and wildlife habitat and recreation, but to a lesser extent than for timber. To the extent that future state forest management paralleled current Tongass management under Forest Service administration, the available multiple resource values from those lands could change significantly under such a proposal. The prospects for such a change cannot be predicted at this time.

Potential Land Exchanges

Administrative land exchanges, in which NFS lands can be conveyed to another entity in exchange for lands of equal value, are another form of land ownership adjustment. Complex land exchanges are sometimes authorized by Congress through special legislation. The Forest Service has completed several land exchanges involving relatively small acreages of Tongass NFS lands. These adjustments are summarized in Chapter 3 of the EIS and include exchanges involving the Kake Tribal Corporation, the Alaska Pulp Corporation and the Kennecott Greens Creek Mining Company, Inc.

There have also been discussions regarding potential future land exchanges between the Forest Service and a number of Native Corporations and other entities that could influence land ownership on the Tongass. As before, for each potential exchange the text includes background information, a description of the conveyance proposal, and a discussion of the potential implications for land ownership and management of the Tongass. In one case, a land adjustment package proposed by the Sealaska Corporation, the Forest Service has received a specific proposal identifying the NFS lands proposed for inclusion in the land adjustment. For that case, the level of available information allows a more specific discussion of the types of lands that would be affected and how their conveyance or exchange might influence forest management.

Shee Atika Cube Cove Proposed Land Exchange

Shee Atika, Incorporated, is an Alaska Native Village Corporation established under ANSCA, representing the historical Native interests of Sitka, Alaska. Through ANSCA, Shee Atika received approximately 23,040 acres in the vicinity of Cube Cove on Admiralty Island. Admiralty Island, for the most part, represents the Admiralty National Monument and surrounds Shee Atika in-holdings. Over the period of enactment of ANSCA to the mid 1990's, Shee Atika harvested the vast majority of the old-growth forests on these lands and at present has no active management taking place. An extensive road system is in place beginning at a log transfer facility in Cube Cove and extending throughout the limits of their lands primarily in the lower reaches of the valleys. The conditions of the roads are unknown.

Proposal and Current Status

Shee Atika formally approached the Forest Service on September 20, 2007, after the Draft EIS was published, proposing a mutual interest agreement to explore the possible exchange of certain NFS lands for Shee Atika surface estate located at Cube Cove. In exchange, Shee Atika is interested in acquiring lands (both surface and subsurface estate) within the Tongass National Forest located on West and North Yakobi Island and on western Chichagof Island. A map depicting the lands they wish to acquire in whole or in part was presented as a general description.

Sealaska, the Alaska Native regional corporation, owns the subsurface estate under the Shee Atika inholdings at Cube Cove. Shee Atika has informed Sealaska of its intent to enter into discussions with the Forest Service. At this time, Shee Atika and the Forest Service have met once to discuss the land exchange concept in general terms only and neither party has made any binding commitments on proceeding further.

Shee Atika's goal for the proposal is to maintain a viable resource and land base for its shareholders. Lands Shee Atika has identified an interest in acquiring are in the Semi-Remote Recreation LUD with a small portion of congressionally designated LUD II within the boundaries.

Table C-1 (at the end of this appendix) has been updated to reflect the acreages included in the proposed land exchange. It indicates the acreage of the NFS lands that could be transferred to Shee Atika via the land exchange components of the proposal, and the acreages of the current Shee Atika lands that could be conveyed to the U.S. This table displays the acreages of the entire pool of parcels. The actual acreage exchanged would likely vary depending on the final lands pool identified, values determined through appraisal, and site-pecific issues raised by the public.

Forest Management Implications

The Forest Service has conducted a cursory evaluation of how the Shee Atika proposal, if implemented as presented, would affect the Tongass Land Management Plan. The evaluation was based on the assumed existing character and resource condition of the respective lands that would be conveyed from Shee Atika to the U.S. and vice versa. It focused on the potential effects on the ability to implement the Old-Growth Conservation Strategy and on necessary changes to the Allowable Sale Quantity for the Tongass. The evaluation also considered subsequent effects on sawmills, karst and cave resources, heritage resources, subsistence hunting and fishing, and public access.

From the limited review, the preliminary determination by the Forest Service is that implementation of the proposal would not require a revision but may require an amendment to the Forest Plan, based on the magnitude of the changes in land base designations. The evaluation assumed that, if all lands in the proposal were transferred, there would be no significant loss of old-growth reserves, no effect on sawmills, no effect on known karst and cave resources, potential effect on heritage resources, no significant effect on subsistence hunting and fishing, and limited effect on public access. This analysis is premised on the limited knowledge given the nature of the proposal and the limited understanding by the Forest Service of what Shee Atika interests are in the lands acquired.

Mental Health Trust Land Exchange

The Trust Land Office (State of Alaska, Department of Natural Resources) manages about one million acres for the Alaska Mental Health Trust land on behalf of the Alaska Mental Health Trust Authority. Resource categories managed by the Trust Land Office include coal, gas, materials, minerals, oil, real estate and timber. The Trust Land Office generates revenues from the Trust land through a variety of methods including sales, long-term leases and short-term land use licenses. Revenues generated from Trust land management are used by the Trust Authority to improve the lives and circumstances of Trust beneficiaries throughout the State of Alaska.

Proposal and Current Status

The Trust Land Office (State of Alaska, Department of Natural Resources) representing the Mental Health Trust Authority, presented a conceptual proposal to the Forest Service on November 20, 2007, after the Draft EIS was published. This proposal offers to exchange approximately 20,000 acres of lands managed by the Trust Land Office in Southeast Alaska for an equal value of Tongass National Forest lands on Prince of Wales Island. The parcels the Trust has offered for exchange are adjacent to or in the immediate vicinities of Skagway, Juneau, Petersburg, Wrangell, Sitka, and Ketchikan. The lands being offered for exchange for the most part are adjacent to NFS lands and, in many cases, form the backdrops, in whole or in part, to the communities identified. Maps depicting these parcels have been provided to the Forest Service for further review and consideration. The lands the Trust has interest in acquiring from the Forest Service are located on Prince of Wales Island and have generally been identified as lands containing the majority of their timber base in young-growth stands. These lands are identified in concept on a map showing areas around Coffman Cove, Staney Creek, Thorne Bay North, Kasaan, Hollis, Twelve Mile Arm, and Polk Inlet.

The Trust has identified two interests as the primary uses of the lands considered for acquisition. These interests include sustained harvest of young-growth timber stands and small parcel developments. The Trust has identified an interest in discussing the possibilities of making all or a portion of the timber volume harvested available to Southeast Alaska processors; allowing access to continue subsistence harvesting by rural residents; and either maintaining or avoiding the Conservation Strategy which the Tongass Forest Plan uses as a foundation for wildlife habitat management.

This proposal, while new, was presented to the Tongass Futures Roundtable for information on December 3, 2007. The Forest Service at this point is considering the concepts of the proposal and has made no agreements on whether or not it will pursue this exchange further.

Forest Management Implications

Given that only preliminary discussions of the proposal have taken place and specific details of the exchange are not available, only general considerations can be made regarding effects. The Forest Service has conducted a cursory evaluation of how the Trust proposal, if implemented as presented, would affect the Tongass Land Management Plan. The evaluation was based on the assumed existing character and resource condition of the respective lands that would be conveyed from the Trust to the U.S. and vice versa. It focused on the potential impacts on the ability to implement the Old-Growth Conservation Strategy and on necessary changes to the Allowable Sale Quantity for the Tongass. The evaluation also considered subsequent effects on sawmills, karst and cave resources, heritage resources, subsistence hunting and fishing, and public access.

From the limited review, the Forest Service preliminary determination is that implementation of the proposal would not require a revision but may require an amendment to the Forest Plan, based on the magnitude of the changes in land base designations. The evaluation indicated that, if all lands in the proposal were transferred, there may not be a significant loss of old-growth reserves; there may not be an effect on sawmills; a potential exists to affect karst and cave resources; a potential effect could occur to heritage resources; there may be an effect on subsistence hunting and fishing; and there is potential for a limited effect on public access. This evaluation is premised on the limited knowledge given the nature of the proposal and the limited understanding by the Forest Service of what the Trust's interests are in the lands acquired.

Table C-1 (at the end of this appendix) has been updated to reflect the acreages included in the proposed land exchange. It indicates the acreage of the NFS lands that could be transferred to the Trust via the land exchange components of the proposal, and the acreages of the current Trust lands offered for consideration that could be conveyed to the U.S. This table displays the acreages of the entire pool of parcels. The actual acreage exchanged would likely vary depending on final lands identified, values determined through appraisal, and site-specific issues raised by the public.

Sealaska Proposed Comprehensive Tongass-wide Land Exchange

The potential exchange that has received the most attention and discussion is known as the Sealaska Proposed Comprehensive Tongass-wide Land Exchange (USDA Forest Service 2005b). This land adjustment package was proposed by the Sealaska Corporation, the Native regional corporation for Southeast Alaska. The package includes two components; one involves an exchange of existing lands owned by Sealaska for existing NFS lands, and the other involves adjustments to Sealaska's land conveyance rights under ANCSA.

ANCSA established processes for transfer of federal land to Alaska Native village corporations and regional corporations, and to Native individuals. ANCSA included two separate provisions addressing land conveyances to Native regional corporations. Under Section 12(c) of ANCSA, 11 regional corporations were to share in the selection of 16 million acres. Section 14(h)(8) set aside a pool of 2 million acres to be transferred to the Native regional corporations in the State after certain other conveyances are completed. After the specified conveyances have been implemented, the remaining land in the pool will be divided among the regional corporations based on population, with approximately 22 percent of the balance going to Sealaska.

Under the applicable ANCSA provisions Sealaska selected approximately 463,000 acres for potential conveyance to the corporation. To date, the U.S. has conveyed approximately 293,000 acres to Sealaska. Sealaska has selected about 171,000 additional acres, which are distributed among nine withdrawal areas defined by ANCSA for Native selections. Based on current information from the Bureau of Land Management, approximately 64,000 of those acres will eventually be conveyed to Sealaska to complete the corporation's land entitlement under ANCSA. (Native corporations were allowed and encouraged to select lands in excess of their entitlements, and the final amount of the Sealaska entitlement has not yet been determined.) Sealaska has approximately 20,000 acres of unconveyed ANCSA entitlement under Section 14(h)(8), in addition to approximately 44,000 acres of 14(h)(8) lands resulting from the 2004 Alaska Land Transfer Acceleration Act, P.L. 108-452.

Proposal and Current Status

In August 2002 Sealaska Corporation submitted a proposal to the Forest Service to exchange approximately 100,000 acres of NFS lands for Sealaska Corporation lands and selection rights under ANCSA. As noted above, Sealaska has approximately 20,000 acres of remaining entitlement under Section 14(h)(8), plus approximately 44,000 acres from P.L. 108-452. The Tongass-wide exchange proposed by Sealaska involves lands throughout Southeast Alaska.

The goals of the proposed exchange are to consolidate NFS lands and Sealaska lands and to finalize Sealaska's remaining land selection rights under ANCSA. Approximately 171,000 acres of the Tongass are encumbered by Sealaska land selections. Resolution of Sealaska's remaining ANCSA land entitlement would remove these selection rights in existing ANCSA withdrawal areas as part of the exchange.

The proposed land exchange package would enable Sealaska to acquire other lands outside of the ANCSA withdrawal areas, in addition to the selected Native heritage 14(h)(1) parcels. This is not authorized under ANCSA except through a land exchange. Land exchanges are discretionary, voluntary real estate transactions between Federal and non-Federal parties. At present there is no binding land exchange agreement signed by the Forest Service and Sealaska that would enable Sealaska to receive lands outside of the withdrawal areas. In the most recent version of its proposal, Sealaska defined what it termed an "entitlement pool" of approximately 123,000 acres, all of which are located outside of the ANCSA withdrawal areas. Sealaska consciously defined the entitlement pool to include substantially more acres than its maximum entitlement amount, to allow flexibility in resolving the proposal. Under the proposal, lands from this entitlement pool of current NFS lands would be conveyed to Sealaska as a substitute for its current entitlement rights. The affected acreage occurs in approximately eight blocks located on Prince of Wales Island (northern, central and southern portions) and on Kosciusko, Tuxekan and Heceta Islands. In addition, Sealaska would transfer to the U.S. lands from a pool of approximately 68,000 acres of existing corporation lands distributed among five withdrawal areas in exchange for lands from a pool of 74,000 acres of current NFS lands. Those lands occur in five blocks located on Kuiu, Kosciusko, Heceta and central Prince of Wales Islands and on the Cleveland Peninsula, and are generally adjacent to areas Sealaska would receive from the entitlement pool. Sealaska would also relinquish claim to the 171,000 acres of lands it has selected within the ANCSA withdrawal areas. Without an appraisal, it is difficult to determine how many acres would be transferred or exchanged under this proposal. Federal law requires that lands or interests to be exchanged must generally be of equal value, based on market value as determined through an appraisal. Both Section 22(f) of ANCSA and Section 1302(h) of ANILCA provide that exchanges shall be based on equal value and contain provisions for cash payments to equalize land values. If the parties agree to an exchange and the Secretary of Agriculture determines it is in the public interest, exchanges may be made for other than equal value.

The Forest Service completed a draft feasibility report on a similar version of this proposal in 2003. After lengthy discussions and several modifications to the proposal, in 2005 the Forest Supervisor informed Sealaska that he was not willing to move forward with the exchange because of a lack of substantial agreement on the parcels to be exchanged, concerns over a variety of resource issues, and the need for a revision to the Forest Plan to accommodate the exchange due to the magnitude of the resulting changes in LUD designations. The response also indicated that the proposal lacked support from local communities and could result in a further decline in the current timber industry dependent on the Tongass for its supply.

There has been no further formal action on the proposed exchange since 2005. The proposed Alaska Land Transfer Acceleration Act of 2003 (Senate Bill 1466) included provisions to implement Sealaska's proposed land exchange, but Congress did not pass this bill. Congress subsequently approved the Alaska Land Transfer Acceleration Act (PL 108-452) in 2004, without the Sealaska exchange provisions. New legislation to authorize the proposed exchange has not been introduced to Congress, although such legislation remains a possibility. Sealaska has been working internally on refinements to the proposed exchange and has shared a variety of preliminary maps with the Forest Service, but to date has not submitted a revised formal exchange proposal for Forest Service review.

Forest Management Implications

The Forest Service conducted a preliminary evaluation of how the Sealaska proposal, if implemented, would affect the Tongass Land Management Plan. The analysis was based on the existing character and resource condition of the respective lands that would be conveyed from Sealaska to the U.S. and vice versa. It focused on the potential impacts on the ability to implement the Old-Growth Conservation Strategy and on necessary changes to the allowable sale quantity for the Tongass. The analysis also considered subsequent effects on local sawmills, karst and cave resources, heritage resources, subsistence hunting and fishing, and public access.

Table C-1 (at the end of this appendix) summarizes the acreages included in the most recent version of the proposed land adjustment and their general location. It indicates the acreage of the entire pool of NFS lands that could be transferred to Sealaska via the entitlement and conveyance (exchange) components of the proposal, and the acreages of the pool of current Sealaska lands that could be conveyed to the U.S. The actual acreage conveyed or exchanged would likely be much less than the listed acres.

From the review the Forest Service determined that implementation of the Sealaska proposal would require a Forest Plan Revision, based on the magnitude of the changes in land use designations. Our analysis showed that, if all lands in the pools were to be transferred, there would be a significant loss of old-growth reserves on the Tongass. There would also be a significant reduction in the Tongass allowable sale quantity (ASQ). In order to make up for the loss of old growth reserve acres, some areas currently in development LUDs would likely be precluded from timber production. This would further reduce the ASQ. In addition, the lands to be exchanged to the U.S. generally do not have existing road systems, and costs for developing roads on these lands would likely constrain the ability to supply timber economically. The combined impacts on the availability of timber from the Tongass could have a significant adverse effect on the supply of timber to mills on Prince of Wales Island and surrounding areas.

In addition, the Sealaska proposal presented to the Forest Service does not provide any assurances that important resources on the lands to be exchanged to Sealaska would be protected to the same degree as under national forest management. Specifically, the proposal does not ensure that the conditions and requirements of the National Historic Preservation Act would be met to protect heritage resources, nor are there assurances that karst and cave resources would be protected. The lands proposed for conveyance to Sealaska also include at least one Research Natural Area and a Special Interest Area. Finally, there are no provisions in the Sealaska proposal that would allow for continued access to lands for subsistence and community recreation purposes. Consequently, resource values to the public from the affected lands could be lost, and subsistence and recreation uses currently occurring on those lands could be shifted to other areas on the Tongass.

Several of the Sealaska parcels that would potentially be exchanged to the United States have high recreation and scenic values and are along established highways or cruiseship and ferry travel routes. Several parcels are important to local communities for dispersed recreation and subsistence activities. Two parcels are noteworthy for heritage resources including one site that is eligible for listing on the National Register of Historic Places. Other of the parcels are known to have well developed karst and/or karst that has been determined to be of high vulnerability. Several of the Sealaska parcels have been harvested. Generally, the unharvested parcels are adjacent to Tongass National Forest lands that have been allocated to non-development LUDS. If acquired by the United States, these parcels might also be allocated to non-development LUDs and may not contribute to the Tongass allowable sale quantity.

Cape Fox Land Entitlement Adjustment

The Cape Fox Corporation is the Native corporation established under ANCSA for the Village of Saxman, which is located near Ketchikan. While Cape Fox was granted entitlement to 23,040 acres within a defined withdrawal area, as were all Native village corporations in Southeast Alaska, its ability to select lands was constrained by the proximity to Ketchikan (Bureau of Land Management 2003). While other village corporations were prevented from making selections within 2 miles of the boundary of home-rule cities, Cape Fox was not allowed to select lands within 6 miles of Ketchikan. In addition, all villages were required to take title to all available land within the core township surrounding the village and were only allowed to select lands within the respective withdrawal areas defined by ANCSA. As a result of these multiple ANCSA restrictions, the only land within the core township available for conveyance to Cape Fox was a 160-acre parcel that Cape Fox did not want, but that the United States was required to transfer to Cape Fox.

For some time there has been interest in legislative action to adjust the selections and conveyances available to Cape Fox. Under ANCSA, village corporations receive only the surface estate for the lands conveyed to them, while the subsurface estate to those lands was transferred to the respective Native regional corporation, which is Sealaska Corporation in the case of Cape Fox. Therefore, to avoid creation of a split estate condition between NFS surface lands and Sealaska subsurface rights, adjustment of Cape Fox selections and conveyances also requires adjustment of Sealaska selections and conveyances.

Sealaska Corporation, Shee Atika, Inc. (the urban Native corporation for Sitka), and the Forest Service have conferred regarding a possible land exchange and purchase since November of 1999, when Shee Atika expressed interest in selling its surface estate to approximately 23,100 acres at Cube Cove, within the Admiralty Island National Monument and Kootznoowoo Wilderness. In April 2000 Sealaska proposed exchanging their subsurface estate to these Cube Cove lands, or other Sealaska subsurface lands or land interests, in exchange for the surface and subsurface of NFS lands of equal value at the Kensington and Jualin Mines near Berners Bay, north of Juneau.

By the fall of 2001 it became clear that the non-federal lands at Cube Cove were no longer offered as part of the exchange proposal, apparently because their preliminary appraisal figures for fair market land values did not meet Shee Atika's expectations. In March 2002 Sealaska revised its proposal to offer approximately 5,200 acres of Sealaska subsurface lands and land interests in exchange for NFS surface and subsurface lands at the Kensington and Jualin Mines. This proposal was captured in a Congressional bill, S. 2222, along with other proposals by Cape Fox Corporation. S. 2222 was passed by the Senate in the 107th Congress, but not by the House.

Proposal and Current Status

Several versions of a Cape Fox Land Entitlement Adjustment bill were introduced to both houses of the 107th Congress in 2002, but were not passed. On April 30, 2003, Congressman Young introduced H.R. 1899, the Cape Fox Land Entitlement Adjustment Act of 2003, in the 108th Congress. On June 26, 2003, Senator Murkowski introduced a similar bill in the Senate, as S. 1354.

H.R. 1899 and S. 1354 provided for an additional 99 acres of ANCSA selection area at Clover Passage (on Revillagigedo Island), for selection by Cape Fox and Sealaska Corporations. The corporations would select these 99 acres from within their existing ANCSA entitlements. These bills also require the Forest Service to offer a land exchange and, if accepted by Cape Fox, to complete a land exchange with the Cape Fox and Sealaska Corporations. Through this land exchange:

1. Cape Fox Corporation would receive the surface and subsurface estates to 2,663.9 acres of NFS lands at the Jualin Mine.
2. Sealaska Corporation would receive the surface and subsurface of NFS lands to equalize values of Sealaska subsurface lands and land interests they convey to the United States. Sealaska Corporation would select NFS lands of equal value from within a 9,329-acre pool of NFS lands at the Kensington Mine.
3. The Forest Service would receive lands and land interests of equal value from within: (a) a pool of approximately 2,900 acres and a public trail easement, offered by Cape Fox (surface) and Sealaska (subsurface) on Revillagigedo Island; (b) 2,506 acres of Sealaska split estate subsurface, located at Upper Harris River and Kitkun Bay (Group 2 Lands); and (c) approximately 2,698 acres of Sealaska subsurface land interests at Kitkun Bay and Dora Lake West, which remain as Sealaska entitlement (Group 3 Lands). Lands in (b) and (c) above are located on Prince of Wales Island and are left over from the Haida Land Exchange Acts and the

Sealaska/Forest Service Split Estate Exchange Agreement of 1991. Cape Fox will choose the lands to be conveyed to the United States from the approximately 2,900-acre pool in (a) above.

Senator Murkowski held a legislative field hearing in Anchorage August 6, 2003, to provide an opportunity for public input and comments on the proposal. She also held a public town meeting in Juneau on September 20, 2003, and an additional legislative hearing March 10, 2004, in Washington, D.C. The Administration supported the legislation, with some minor changes to clarify valuation standards, extend required time frames, and provide for environmental survey and remediation standards. The 108th Congress did not pass the legislation, however.

On April 7, 2006 Senator Murkowski introduced S. 2615, "to provide equitable treatment for the people of the Village Corporation established for the Native Village of Saxman, Alaska, and for other purposes," in the 109th Congress. This bill waived the requirement under ANCSA Section 16(b) that the U.S. convey and Cape Fox receive the 160-acre parcel discussed above, and provided for conveyance of the surface estate for the 99 acres at Clover Passage to Cape Fox (with the subsurface estate going to Sealaska). This bill did not address the other land conveyances proposed in H.R. 1899/S. 1354 (see items 1-3 above), although it did state that conveyance of the 99 acres identified in Section 3(a) of the bill would be considered to fulfill the entitlement of Cape Fox under ANCSA Section 16(b). This bill was not passed by the 109th Congress. The bill was mostly recently introduced on January 8, 2007 as Senate Bill 203 in the 110th Congress.

Forest Management Implications

The Cape Fox land entitlement adjustment proposal introduced in 2003 is a relatively complex package of selections, conveyances and exchange actions that could affect a number of NFS parcels and have a variety of effects on Tongass management. Under that proposal, Cape Fox and Sealaska would convey to the Forest Service the surface and subsurface rights to approximately 2,900 acres on Revialgigedo Island, and Sealaska would convey to the Forest Service the subsurface rights to approximately 5,200 acres on Prince of Wales Island. Surface management of those lands on Revillagigedo Island would likely remain unchanged, while the Forest Service would need to administer a split-estate condition for the lands on Prince of Wales Island. In return, Cape Fox would receive surface and subsurface rights to nearly 2,700 acres of NFS lands and Sealaska would select up to 9,300 acres of NFS lands with a value equal to the 5,200 acres of subsurface rights. The Native corporations would presumably receive lands with high mineral values located near existing mineral resources (the Jualin and Kensington mines), which could change the jurisdiction over future mining activities. While these conveyances could ultimately be of note from a financial perspective, they would affect relatively small areas and probably would not change the likelihood of expanded future mineral development in the subject locations.

Senate Bill 2615, introduced in 2006, and the current version, Senate Bill 203 would have a minor effect upon Tongass management. The 99-acre parcel to be conveyed to Cape Fox Corporation is adjacent to lands owned by Cape Fox, other private owners, and the State of Alaska. Currently this parcel is managed as scenic viewshed, a moderate development LUD. This bill would also complete Cape Fox Corporation's ANCSA entitlement resulting in the removal of selection encumbrances on approximately 800 acres of NFS lands.

Summary Discussion

Table C-1 summarizes the key parameters of the proposed land conveyance and exchange programs discussed in this appendix. For each proposal, the table indicates the maximum acreage of Tongass lands that could be transferred to other ownership, acreage that could be added to the Tongass land base, the general location of the action (if identified in the proposal), whether the proposal is intended to complete an existing entitlement, and the type of land involved (if known or inferred).

Table C-1
Summary of Potential Land Adjustments

Conveyance or Exchange Proposal	Max. acres from NFS	Max. Acres to NFS	Likely Tongass Location	Entitlement Completion?	Type of Land
University of Alaska Lands, Senate Bill 293	250,000	0	Unknown	No	*Second-growth cut since 1952*
Unrecognized SE AK Native Communities, Senate Bill 1306	115,200	0	Near Haines, Ketchikan, Petersburg, Tenakee Springs, Wrangell	No	*Development LUDs?*
Alaska Native Veterans Land Allotment Equity Act, Senate Bill 2000	55,000 est.	0	Unknown	No	*Homesites, recreation lands?*
Alaska State Forest proposal	2,000,000	0	Prince of Wales island	No	*Timber Production*
Southeast Alaska Native Land Entitlement Finalization Act* or Sealaska Proposed Comprehensive Tongass-wide Land Exchange	203,000	68,000	Widely distributed	Yes, outside of ANCSA withdrawal areas. Also exchange other lands	*Varied*
Shee Atika	±23,000	±23,000	West and North Yakobi & Northwest Chichagof	No	*Semi-Remote Recreation*
Mental Health Trust	±20,000	±20,000	Prince of Wales Island	No	*Timber Production (young growth)*
Cape Fox Entitlement Adjustment, Senate Bill 2615	99	0	North of Ketchikan	Yes, outside of ANCSA withdrawal area	*Moderate Development LUD*
Total	2,666,000	111,000			

*Assumes economic development lands similar to what depicted in DEIS. An additional 3,600 acres are added for sacred, cultural, traditional, or historic significance, as well as 5,000 acres for Native enterprise sites.

When considered as individual actions, several of the land adjustment proposals discussed above appear to be relatively minor in scope and potential effect, and/or the implications of the proposal for Tongass management are difficult to determine due to lack of specificity in the proposal. Conversely, some of the proposals could result in substantial changes to the NFS land base and prompt corresponding adjustments in Tongass management.

The Forest Service believes that it is unlikely that all of the identified conveyance and exchange proposals would be enacted and/or implemented. Because some of the proposals involve larger acreages and it is conceivable that multiple proposals could be adopted; however, it is appropriate to consider the range of implications for management of the Forest. Pertinent observations based on considering the conveyance and exchange proposals collectively include the following:

- These proposals generally target, or would be likely to focus interest on, Tongass lands that are currently managed for resource development activities. Conveyance of these lands out of federal ownership would decrease the acreage available for development activities on the Tongass.
- If all of the proposals were enacted and implemented, it could conceivably result in transfer/exchange/conveyance of over 2 million acres from the Tongass, representing approximately 15 percent of the current NFS land base.

- Conveyance of large blocks of land under several of these proposals would consolidate certain other ownerships while likely further fragmenting the federal land ownership pattern within the Tongass.
- While new owners of former Tongass National Forest lands would presumably pursue resource development objectives on much or most of the affected acreage, it is unlikely that all new owners would continue the currently applicable protection measures for cultural and ecological resources, or continue to supply timber to local mills at current rates.
- It is unlikely that all new owners would allow public access to the affected lands for subsistence, recreation, and similar public uses, resulting in a reduction in the set of opportunities currently available for these purposes.

As it has in the past, the Forest Service will evaluate any new or modified proposals for administrative land exchanges for their consistency with applicable NFS planning and management direction. The Forest Service will follow Congressional direction in implementing future land adjustments that might be enacted by Congress, and will modify Tongass National Forest planning and management as needed in response to such changes.

APPENDIX D
OLD-GROWTH HABITAT CONSERVATION STRATEGY, WILDLIFE STANDARDS AND GUIDELINES, AND WILDLIFE VIABILITY

Appendix D

Old-Growth Habitat Conservation Strategy, Wildlife Standards and Guidelines, and Wildlife Viability

CONTENTS

LIST OF TABLES

1. INTRODUCTION

This appendix provides a description of the background, rationale, and assumptions, for the changes to the Tongass old-growth habitat conservation strategy, proposed by the alternatives evaluated in the 2008 Forest Plan amendment Final Environmental Impact Statement (FEIS). In addition, it describes the assumptions and rationale for application of the wildlife viability ratings to the alternatives. This appendix brings forward and updates information contained in Appendix N to the 1997 FEIS.

Chapter 2 addresses the old-growth habitat conservation strategy. It includes a summary of the historical background, a description of the 1997 strategy including modifications to the strategy between 1997 and 2007, and an overview of the new science that is relevant to the strategy. Sections 2.1 and 2.2 begin by presenting the historical background of the strategy and describe the strategy, as it was proposed in 1997. These two sections are largely summarized from Appendix N to the 1997 FEIS. Section 2.3 summarizes the modifications to the strategy that have occurred through Forest Plan amendments and land adjustments from 1997 through 2007 and Section 2.4 summarizes new relevant science that has been developed since 1997.

Modifications to the strategy proposed by the 2008 FEIS alternatives are described in Section 2.5. In this FEIS, Alternative 5 (No Action) incorporates the 1997 strategy, as modified between 1997 and 2007, while the six action alternatives propose modifications. Alternatives 1, 2, 3, and 6 propose the same refined network of Old-Growth Habitat Land Use Designations (LUDs) and incorporate the same changes to the wildlife standards and guidelines, but differ in the amount and distribution of some of the other non-development LUDs that also comprise the reserve system. Section 2.5 describes the background, rationale, and modifications to the strategy proposed by these four alternatives. These modifications include changes to the old-growth reserve (OGR) network, changes in other non-development LUDs, and changes to species-specific standards and guidelines. Alternatives 4 and 7 propose more extensive changes to the conservation strategy and standards and guidelines. Section 2.5 also summarizes the rationale and changes to the strategy incorporated in these alternatives. The changes for all of the alternatives are compared to Alternative 5 (the 1997, as amended, Forest Plan).

In 1995/1996 and 1997 a series of expert risk assessment panels were conducted to evaluate the various alternatives used in the 1997 FEIS and predecessor documents. The purpose of the panels was to evaluate various alternatives for the likelihood of maintaining sufficient, well distributed habitat to maintain viable populations of old-growth associated wildlife species over a 100-year horizon. These panel assessments, along with new information and an alternate method, were used as a tool to evaluate wildlife viability for the 2008 FEIS alternatives. Chapter 3 describes the panel assessments, summarizes results of the panel assessments that are relevant to the 2008 alternatives, discusses new relevant science, and then summarizes the application of the panel assessments to the 2008 alternatives, including rationale and assumptions. Section 3.1 presents historical background for the Tongass wildlife risk assessment panels and ratings, Section 3.2 describes the panel assessment process, and Section 3.3 summarizes the 1995/1996 and 1997 panel assessment results. These first three sections of Chapter 3 are largely summarized from the risk assessment panel reports and Appendix N to the 1997 FEIS. Section 3.4 summarizes new science related to wildlife viability assessment that has been developed since 1997. The application of the 1995/1996 and 1997 panel assessments to the 2008 FEIS alternatives is described in Section 3.5. Finally, Section 3.6 presents an alternative approach to assessing viability.

Chapter 4 presents a summary of the major conclusions that are relevant to the 2008 Forest Plan amendment and the alternatives evaluated in the EIS. Finally, Chapter 5 lists the references cited.

2. OLD-GROWTH HABITAT CONSERVATION STRATEGY

2.1. Historical Background of the Conservation Strategy

2.1.1. Overview

An integrated science-based old-growth forest habitat conservation strategy was developed and adopted during the 1997 Forest Plan Revision process. The old-growth strategy has two basic components. The first is a forest-wide reserve network that protects the integrity of the old-growth forest by retaining blocks of intact, largely undisturbed habitat. The OGRs include a system of large, medium, and small Habitat Conservation Areas (HCAs) allocated to the Old-Growth Habitat LUD, and full protection of all islands less than 1,000 acres in size. The reserve network also includes all other non-development LUDs. These include Wilderness, National Monument, Legislated LUD II, Wild River, Remote and Semi-Remote Recreation, Research Natural Area, Municipal Watershed, and all other LUDs that essentially maintain the integrity of the old-growth ecosystem. The second component of the old-growth habitat conservation strategy is management of the matrix, e.g., the lands with LUD allocations where commercial timber harvest may occur. Within the matrix, components of the old-growth ecosystem are maintained by standards and guidelines to protect important areas and provide old-growth forest habitat connectivity. The analysis presented in this section describes the rationale for the strategy and its specific components.

Development of the old-growth strategy relied on several key scientific documents that provided the basic foundation for addressing wildlife viability. These included the Interagency Viable Population Committee (VPOP) Conservation Strategy (Suring et al. 1993), the Pacific Northwest Research Station Peer Review of the VPOP Strategy (Kiester and Echkardt 1994), and the VPOP Response to the Pacific Northwest Research Station Peer Review (Suring et al. 1994). In addition, the Alexander Archipelago Wolf (Person et al. 1996) and Northern Goshawk (Iverson et al. 1996) conservation assessments provided the basis for design of some components of the strategy as well as a basis for examining whether the old-growth strategy would sustain viable and well-distributed populations of these two species. This section provides a discussion of the major features, findings, and recommendations of each of the three conservation planning (VPOP-related) documents, a consideration of features and recommendations in each document, and the integration of features in the deliberative process to arrive at an overall strategy to address viability of old-growth associated species. As such, it represents a summary of much of the information presented in Appendix N to the 1997 Forest Plan.

2.1.2. Habitat Reserve Approach

There is a substantial science base for an old-growth habitat reserve approach for addressing wildlife viability. Habitat reserves have often been the focal point of conservation strategies since the pioneering work of MacArthur and Wilson (1967) on the theory of island biogeography: that the equilibrium number of species on an island generally depends on island size, and island distance from (usually mainland) source populations. Reserves are viewed as islands of undisturbed or natural habitat within a landscape of management-altered or dissimilar habitat. Reserves attempt to protect the integrity of an isolated landscape. From this theory, five general concepts of reserve design have evolved in conservation planning (Thomas et al. 1990):

- ♦ Well-distributed species are less prone to extinction than species confined to small portions of their range;
- ♦ Larger reserves supporting many pairs of individuals are superior to smaller reserves supporting only a few pairs;
- ♦ Reserves that are close together are better than ones far apart;
- ♦ Reserves should have the least amount of induced fragmentation possible; and

- Reserves should be connected, either through specific corridors (such as beach fringe or riparian areas) or through maintaining habitat characteristics similar to the reserves on the lands between them.

A reserve-based strategy relies on blocks of intact, largely undisturbed habitats (such as old-growth forest) of the appropriate size, spacing, and composition to meet a desired design that will maintain viable, well-distributed populations of one or more species. The HCA network used for the conservation of spotted owl habitat in the Pacific Northwest is a classic example (Thomas et al. 1990).

Potential drawbacks of a reserve approach are the failure to consider natural disturbance processes-the dynamic nature of ecosystems, and not being able to preserve landscape integrity (Irwin and Wigley 1992). These can be overcome by combining a reserve system with some type of matrix management approach (Thomas et al. 1990, Franklin 1993). As a complement to reserves, matrix management can serve at least three important roles: 1) providing habitat at smaller spatial scales, 2) increasing the effectiveness of the reserves, and 3) improving landscape connectivity.

2.1.3. VPOP Strategy

The Interagency Viable Population Committee (VPOP) performed pioneering work in designing a landscape conservation strategy to address wildlife viability. Their strategy and extensive supporting analysis are contained in *A Proposed Strategy for Maintaining Well-Distributed, Viable Populations of Wildlife Associated With Old-Growth Forests in Southeast Alaska* (Suring et al. 1993). VPOP was commissioned by the Tongass Land Management Plan (Forest Plan) Revision Team to provide recommendations for sustaining habitat to help ensure the maintenance of well-distributed viable populations of all old-growth associated wildlife species across the Tongass. VPOP systematically screened all wildlife species and identified those old-growth associated species they considered to be most sensitive to habitat loss and fragmentation of the old-growth ecosystem. Their ‘coarse filter’ landscape strategy designed to consider the entire complement of old-growth associated species, included a system of large (40,000-acre) and medium (10,000-acre) HCAs with spacing and habitat composition requirements well distributed across the Tongass. Small (1,600-acre) HCAs in each major watershed (>10,000 acres) and individual species-specific management guidelines also were recommended.

Landscape connectivity was an integral feature of the original VPOP landscape conservation strategy (Suring et al. 1993). VPOP reviewed the available literature and concluded that there was limited empirical support for corridors but that this should not preclude their inclusion in landscape conservation planning. They reasoned that landscape habitat connectivity was an important component of conservation planning to facilitate animal dispersal and movement, whether specifically designed as corridors or through overall management of a habitat matrix. They recommended a 500-foot beach fringe buffer Forest-wide and 200-foot buffers on anadromous fish streams. Breaks in these buffer corridors should be less than 65 feet to facilitate flying squirrel dispersal.

VPOP mapped the large and medium reserves and provided guidance for locating the small reserves, stating that their mapping effort represented only one possible application of the OGR system across the forest. VPOP concluded that their strategy represented “the minimum amount and distribution of habitat necessary to assure a high likelihood of maintaining viable, well-distributed populations of old-growth associated wildlife species across the Tongass National Forest” (p. 37).

2.1.4. Pacific Northwest Research Station Review

The Forest Service Pacific Northwest Research Station was requested by the Alaska Region to conduct an independent scientific peer review of the VPOP strategy. Kiester and Eckhardt (1994) obtained technical reviews from 18 scientists from North America with substantial knowledge and experience in species ecology or conservation biology. Kiester and Eckhardt (1994) synthesized these technical reviews and published all reports in the document *Review of Wildlife Management and Conservation Biology on the Tongass National Forest: A Synthesis with Recommendations* (Pacific Northwest Research Station Review).

The general concepts in VPOP's multiscale habitat conservation strategy received positive support from the scientists involved in the Pacific Northwest Research Station Review: Beckman (p. 37): "The proposal of HCAs of three sizes somewhat uniformly scattered across the landscape seems like a reasonable strategy..."; Forsman (p. 48): "...proposed network of conservation areas is a reasonable start in combination with protection of known (goshawk) nest areas within the matrix."; Hansen (p. 50): "The core approach of this report (strategy) is scientifically sound and generally consistent with modern conservation biology."; Jarvis (p. 71): "The strategy is an innovative and bold attempt to apply species, community, and ecosystem concepts to applied management."; Lande (p. 78): "...a good initial attempt to develop a strategy for maintaining biodiversity."; Lidicker (p. 87): "The strategy outlined is a giant step in the right direction, but improvements are needed..."; Marcot (p. 101): "...the process and basis for the proposed conservation strategy is scientifically sound given our current knowledge base..."; and Walters (p.194): "...the overall management strategy that considers landscape level features is excellent. The approach is well-grounded in the best current information in conservation biology...". Kiester and Eckhardt (p. 5) concluded in their summary review that "the Strategy (VPOP) receives high marks. It represents a solid attempt to integrate species viability concerns with the HCA approach."

The Pacific Northwest Research Station Review identified several weaknesses in the VPOP strategy. For example, corridors were considered inadequate, there was insufficient attention directed to the matrix lands, and HCAs were considered to be too small by many scientists. Kiester and Eckhardt (1994 p. 5) concluded that "the particular pattern of HCAs that it [the VPOP strategy] suggests will not ensure viability of all species"--although no individual species were specifically identified. Careful examination of all reports by the 18 scientists that participated in the Pacific Northwest Research Station Review revealed repeated concerns relative to brown bears and wolves (Lande p. 82; Lidicker p. 91; McLellan p. 132, Paquet p. 143; Pletscher p. 147; Powell p. 156, and in the summary by Kiester and Eckhardt, p. 16, 17) and that 40,000-acre large HCAs recommended by VPOP were too small to sustain populations of these wide-ranging species. Lande recommended that at least one very large HCA be maintained in each ecological province or island (p. 81); Lidicker recommended a "few large areas, one per island or island group" (p. 91); McCullough (p. 116) recommended fewer but larger HCAs to support continuous populations; and Pletscher (p. 147) suggested an "inverse HCA" concept of very large preserved landscapes with small areas allocated for timber harvest.

Importantly, Kiester and Eckhardt (1994, p.3) noted that the Pacific Northwest Research Station Review only considered the network of mapped VPOP large and medium HCAs and Congressionally protected areas such as Wilderness, Monuments and Legislated LUD II areas. The VPOP reserve network was not examined in the context of the entire forest plan or a fully articulated planning alternative containing the strategy. The scientists were unable to consider other LUDs that effectively function as reserves and conserve the old-growth ecosystem—a very important component incorporated into the development of the old-growth habitat conservation strategy in the revised Forest Plan and this analysis.

Corridors and landscape connectivity received considerable attention among the scientists involved in the Pacific Northwest Research Station Review, and somewhat differing opinions emerged regarding how to address landscape connectivity. Lidicker recommended 1,000-foot corridors (p. 91), while Lande (p. 82) recommended corridors of up to 4,000 feet wide. Other scientists questioned the value of explicitly designed corridors. McCullough (p. 116) noted that "corridors are of considerable debate" and recommended larger reserves to minimize reliance on dispersal corridors; Paquet (p. 137) stated "there are few controlled data with which to assess the conservation role of corridors, thus it is difficult to support or refute their value" but added "…maintenance or restoration of connectivity in the landscape is a prudent strategy"; Pletscher (p 147) stated "There are few empirical studies documenting the value of narrow corridors" and recommended more attention be focused on overall management of the matrix; and Powell (p. 154) agreed with VPOP regarding uncertainty of corridors and recommended more attention be given to the intervening landscape matrix to facilitate wildlife movement and dispersal. Kiester and Eckhardt (p. 17) stated that overall landscape connectivity was an essential component of an old-growth conservation strategy and wider corridors were necessary (especially for marten), particularly relative to ecological pinch points, but cautioned that corridors are "virtually untested in practice."

In their summary chapter, Kiester and Eckhardt (1994) provided many recommendations that specifically relate to forest planning and features of landscape design:

- Existing largest blocks of contiguous high-volume old-growth forest should not be further fragmented by timber harvesting or road building.
- Incorporate larger reserves.
- Incorporate wider corridors.
- Do not differentially cut low altitude, high-volume old growth
- Consider an inverse HCA concept.

They provided many other sound management recommendations not directly related to landscape planning design, such as adaptive management, biological inventory, gap analysis, and population viability analyses.

2.1.5. VPOP Response

Suring et al. (1994) specifically responded to individual recommendations made in the Kiester and Eckhardt (1994) review of the VPOP Conservation Strategy in the document: *Response to the Peer Review of: A Proposed Strategy for Maintaining Well-distributed, Viable Populations of Wildlife Associated with Old-Growth Forests in Southeast Alaska* (VPOP Response). In this brief (11 pages with appendices) response, Suring et al. (1994) indicated that the document represented an "initial response" outlining additional elements that would be considered in their preparation of a final Conservation Strategy as provided for in the peer review process, stating "additional support will be needed by the Committee (VPOP) from the Forest Service to adequately incorporate the recommendations of the peer reviewers into our manuscript and to publish that manuscript" (Suring et al. 1994, p. 3).

Within the VPOP Response, seven specific recommendations were made that were responsive to Pacific Northwest Research Station Review comments. All recommendations were considered during the Viability Synthesis Workshop (Iverson and Rene, 1997) to identify building block concepts for forest plan alternative development. All VPOP Response recommendations were analyzed spatially and quantitatively (Iverson 1996a). In doing so, the Forest Plan interdisciplinary team (IDT) concluded that the features described in the recommendations would not collectively represent a fundamentally different alternative than existed within the range for forest plan alternatives considered in the Revision planning process and that general concepts recommended (e.g., larger reserves and wider corridors) were already addressed.

Specifically, from the Pacific Northwest Research Station Review recommendation to "keep landscape options open, and do not further fragment existing large blocks of high-volume old growth," the VPOP Response generated the following recommendation: "it is important that the largest remaining patches not be fragmented. This may (emphasis added) be accomplished by restricting logging and road building to areas other than the three largest old-growth forest patches within each ecological province" (p.8). The Pacific Northwest Research Station Review referred to blocks of old growth while the VPOP response referenced "patches"; the Pacific Northwest Research Station Review recommendation specifically mentioned "high-volume" old growth—VPOP did not; the VPOP Response only recommended that the three largest old-growth forest patches be protected—the Pacific Northwest Research Station Review suggested all blocks. Despite slight but important differences between these two recommendations, the Forest Service concluded that minimizing additional fragmentation of large areas of old-growth forest with a focus on the high-volume class strata was the basic intent of the recommendations.

Noting the limitations in their original conservation strategy identified by the Pacific Northwest Research Station Review, the VPOP Response considered the diversity of opinion among the scientists concerning corridors and provided a series of explicit corridor recommendations. They recommended that a beach fringe corridor of 3,300 feet be established Forest-wide within which only selective uneven-aged management could be applied. They also recommended that 1,000-foot and 1,600-foot no harvest corridors be designated to connect medium and large HCAs, respectively. These corridors should be located below 800 feet in elevation.

2.2. The 1997 Old-Growth Conservation Strategy

The 1997 Forest Plan IDT carefully reviewed the landscape design recommendations contained in the documents discussed above. In consideration of all multiple-use issues and concerns, they designed a habitat strategy that was responsive to the recommendations contained in these documents. This strategy represents the integration of many elements, some of which are specific to addressing wildlife viability, others of which respond to other issues, such as Congressional legislation (Wilderness, National Monument, and Legislated LUD II), riparian habitat management from the Anadromous Fish Habitat Assessment, or the allocation of lands to Remote and Semi-Remote Recreation in recognition of recreation and tourism uses.

After considering the Pacific Northwest Research Station Review by prominent scientists and considering all other available information, the IDT incorporated the VPOP HCA strategy as the cornerstone of the old-growth forest habitat strategy in the 1997 revised Forest Plan. This represents a fundamental 'coarse filter' approach to addressing wildlife viability and the conservation of biodiversity. In addition, a variety of other coarse filter standards and guidelines provided connectivity between the reserves. At the "fine filter" level, species-specific standards recommended by VPOP (e.g., brown bear, goshawk, wolf, great blue heron, etc.) were fully considered in light of additional information such as conservation assessments, panel assessment results, etc. and appropriate standards and guidelines were incorporated into the Threatened, Endangered, and Sensitive Species and Wildlife sections of the Forest Plan for species that needed additional protection measures to assure their viability and well-distributed status.

The following sections describe the strategy. First, the Forest-wide reserve network is discussed. Next, the management of lands outside the reserve network (the "matrix") is described with subsections on each category of standards and guidelines that affect this management.

2.2.1. Forest-wide Habitat Reserve Network

2.2.1.1. Introduction

The coarse-filter approach was designed to maintain a functional and interconnected old-growth ecosystem, which in turn will maintain the component parts (composition and structure) and processes (function) of that ecosystem (p. 3-11, U.S.D.A. 1997c). In general, the home range and dispersal capabilities of old-growth associated species of concern were considered in determining the size, spacing, and number of reserves.

The system of Forest-wide habitat reserves adopted by the Forest Plan consists of large, medium, and small reserves. Of the estimated 5 million acres of productive old growth (POG) in 1997, the reserve system sets aside 3.6 million acres, and nearly 1 million additional acres are protected through the various standards and guidelines prescribed for management of the lands outside the reserves (U.S.D.A. 2003). The percentage of POG reserved within each of the 21 biogeographic provinces on the Tongass ranges from 38 to100 percent (Iverson and DeGayner 1997). The percent of the reserve system that is high-volume old growth (greater than 25,000 board feet per acre) is slightly higher than the Forest-wide average (44 percent and 43 percent, respectively) (U.S.D.A. 1997a).

2.2.1.2. Description and Design Features of the Reserve Network

A summary description of the reserve types, as they were defined in the 1997 Forest Plan, is provided below. In addition, details regarding the design features of the reserve network are presented following the description.

Description and General Design of Each Reserve Type

Large Reserves:

- There are 38 large reserves on the Tongass. These are contiguous landscapes, typically at least 40,000 acres in size and including at least 20,000 acres of POG forest. At least 10,000 acres of POG was intended to be in the high-volume stratum. Large reserves consist of a variety of non-development LUDs including the Old-Growth Habitat LUD.

- Large reserves are intended to be no more than 20 miles apart and are distributed across the entire Forest. Large reserves within the range of brown bears were intended to have at least one Class I anadromous fish stream.

Medium Reserves:

- The Tongass includes 112 medium reserves. These are contiguous landscapes of approximately 10,000 acres including at least 5,000 acres of POG forest. At least 2,500 acres of the POG was intended to be in the high-volume stratum. Medium reserves consist of a variety of non-development LUDs including the Old-Growth Habitat LUD.
- Medium reserves are intended to be no more than 8 miles from the nearest large or medium reserve and are distributed across the entire Forest.

Small Reserves:

- The Tongass includes a network of 237 small reserves, which are defined by Old-Growth Habitat LUDs. They generally contain at least 16 percent of the area of a value comparison unit (VCU) in a contiguous landscape, with at least 50 percent of the area in POG forest.
- They typically contain a minimum of 400 acres of POG.

Small Islands:

- The Tongass Forest Plan protects all islands less than 1,000 acres from additional harvest of old-growth forest. These areas are mapped as non-development LUDs, typically Semi-Remote Recreation.

Additional Design Features and Assumptions of Reserve Network

This section describes additional design criteria and assumptions used to design the OGRs system. A basic assumption was that future reviews of most individual medium and large OGRs or reviews of the entire conservation strategy would need to consider the total acres of old-growth habitat and other non-development LUDs that maintain the integrity of the old-growth forest ecosystem and contribute to a Forest-wide system of reserves within National Forest System lands. Islands less than 1000 acres that are designated as non-development LUDs may be excluded from acreage calculations.

General Design Criteria

A. OGRs were located so that spacing is maintained in the four cardinal directions.
B. Reserves are more circular rather than linear in shape to maximize the amount of interior (secure from the effects of forest edge) forest habitat.
C. The amount of early seral habitat within mapped reserves was minimized to the extent feasible. In VCUs where managed stands constitute a high portion of the total acres, including seral habitat that previously supported high volume stands to the OGR was favored if it achieved a more circular shape, maintained connectivity or included rare habitats (e.g., karst).
D. The amount of roads and log transfer facilities within mapped reserves were minimized to the extent feasible.
E. Riparian, beach and estuary habitats were considered as contributing elements to OGRs.
F. Site-specific factors in placing reserves were considered to help meet multiple biodiversity or wildlife habitat objectives. Factors included, but were not limited to:
   1. The largest remaining blocks of contiguous old growth within a watershed. Old-growth forest that constitutes scattered fragments of unsuitable timberland generally did not contribute to meeting small reserve design.
   2. Rare features such as underrepresented forest plant associations or stands with some of the Forest’s highest volume timber stands.
   3. Known or suspected goshawk nesting habitat.
   4. Known or suspected marbled murrelet nesting habitat.

5. Important deer winter range to maintain important deer habitat capability to meet public demand for use of the deer resource.

There was no requirement to ensure connectivity among all small OGRs or between small OGRs and non-development LUDs (which form parts of large and medium OGRs). POG forest occurring within other features of the strategy (e.g., beach fringe, riparian, other non-development LUDs) contributes to overall landscape connectivity in the evaluation. It was anticipated that there would be a need to provide additional corridors only in rare situations. Medium and large OGRs were designed to provide connectivity between other old-growth LUDs and other non-development LUDs. The following parameters were used to ensure OGRs maintained connectivity.

A. Only one connection in one direction was necessary.
B. The beach fringe serves as a connector.
C. The connection did not have to be the shortest distance.

Additional Criteria for the Design of Small OGRs

This subsection provides a summary of additional criteria that were used in the design and layout of small OGRs.

A. Small OGRs were not required under the following circumstances:
   1. In VCUs where the total acres and acres of POG within non-development LUDs met or exceeded the minimum acreage criteria.
   2. In VCUs with a computational allocation of less than 800 acres of POG forest. An OGR may have been designed contiguous with old-growth acres in a non-development LUD in an adjacent VCU.
   3. In VCUs that were partially designated as very large, large, or medium OGRs even if these did not meet the minimum acre criteria for a small OGRs. In some cases, small OGRs have been designated in these VCUs for specific purposes.

B. Small OGRs may have been designated under the following circumstance:
   1. VCUs that have been separated may have been combined for computational purposes. These VCUs are denoted by an integer other than zero as the fourth digit of the VCU number (e.g., 5971, 5972, 5973). An OGR was located in at least one of these VCUs. In some cases, small OGRs were designated in more than one of these VCUs for specific purposes.

2.2.1.3. Rationale for the Reserve Network

The mapped system of 150 large and medium HCAs originally designed by VPOP as "one possible application of the proposed strategy" was integrated into the Forest Plan through allocation to the Old-Growth Habitat LUD and other non-development LUDs. Spatial modifications to the original VPOP large and medium HCAs were made; this is provided for in the VPOP report as long as HCA design criteria for size, spacing, and composition are maintained (Suring et al. 1993, p. 30). In their HCA composition analysis, Suring et al (1993) also identified limitations in their mapped strategy. Subsequent modifications were made to large and medium HCAs to correct limitations. Modifications were made for several reasons:

- The original VPOP delineation did not meet minimum HCA criteria (e.g., St. James Bay Large HCA);
- The original delineation incorporated large amounts of fragmented clearcut landscape (e.g., Couverden and Kelp Bay large HCAs);
- The original VPOP delineation exceeded minimum criteria (Ratz Harbor, Aaron's Creek medium HCAs);
- The integrity of the original HCA was substantially compromised by recent timber harvest that was inconsistent with HCA objectives (Game Creek Large HCA); and
- The reserve location was adjusted to achieve multiple-use objectives such as timber harvest.

Even after these modifications, all large and medium HCAs do not precisely match the specific VPOP size, spacing and habitat composition design criteria. Based on a detailed analysis of how well the original mapped VPOP reserves and the design criteria were integrated into the 1997 Forest Plan (Iverson 1997), VPOP found that over 90 percent of the 149 HCAs they mapped forest-wide met the minimum spacing criteria, and those that did not were generally isolated islands or within Wilderness (Suring et al. 1993, Table 8, 9). Very few HCAs were completely moved (Iverson, 1997); thus the current location of mapped reserves is considered in general compliance with the original VPOP design. While site-specific compliance is not always perfect, either exceeding or occasionally deficient in VPOP design criteria, fine-tuning application of the strategy would take many iterations. As VPOP concluded, "a 'perfect' application of this conservation strategy does not exist" (Suring et al. 1993, p. 35). Furthermore, standards and guidelines in the Old-Growth LUD provide for the examination of the size, spacing, and composition criteria for each reserve at the project level and provide for necessary adjustments to ensure minimum design criteria are met.

Small (1,600-acre) HCAs in each 10,000-acre watershed were recommended by VPOP, to be mapped during project implementation. VPOP identified two objectives for small HCAs (Suring et al. 1993, p. 28): "to provide temporary functional habitat for animals dispersing between large and medium HCAs and to ensure that species of concern have a relatively high likelihood of occurring in each 10,000+ acre watershed." The IDT identified and explicitly mapped the small reserves in the Forest Plan as part of the Old-Growth LUD. These small reserves also contribute to the overall landscape matrix outside large and medium HCAs (see Section 2.2.2 Matrix Management). Approximately 237 small reserves were mapped. These included nearly 267,000 acres of POG forest within a total of 480,000 acres (Appendix 1 to Appendix N of the 1997 Forest Plan Revision FEIS). These reserves represent an important component of the Forest-wide old-growth habitat conservation strategy.

The need for larger habitat reserves (larger than provided by VPOP) and minimizing fragmentation, in general, and specifically for brown bears and wolves, was a consistent recommendation expressed by the Pacific Northwest Research Station Review scientists. The 1997 Forest Plan, in response to observations of the Pacific Northwest Research Station Review scientists and management considerations contained in the interagency wolf conservation assessment, contained at least one very large reserve within each of the 21 biogeographic provinces across the Tongass to address large-scale distribution of large OGRs (Appendix 5 to Appendix N of the 1997 Forest Plan Revision FEIS). This action was specifically responsive to Lande's recommendation (p. 81, in Kiester and Eckhardt 1994) of one large reserve per province and to other scientist's concerns that VPOP's HCAs were too small. A quantitative definition of large was not provided in any reference; however, multiples in excess of the VPOP large HCAs of 40,000 acres may be considered as 'large' (1-2 times as large) or 'very large' (3 or more times as large).

The VPOP Response also recommended the following: "it **may** (emphasis added) also be necessary to establish 0.5- to 1-mile buffers around all large and medium HCAs as a "special management zone" permitting removal of up to 25 percent of the standing volume in 5-acre units using uneven-aged timber management. This recommendation relates to the need for larger old-growth forest reserves. This feature has been incorporated into the Forest Plan in a different way than proposed in the VPOP Response. As discussed above, at least one very large reserve per province was allocated. Furthermore, the VPOP Response recommendation would have permitted substantial harvest (up to 25 percent) of the expanded area. The Forest Plan protects entire reserves without selective harvest and associated additional reduction of old-growth forest.

Both the Pacific Northwest Research Station Review and VPOP Response expressed concern for disproportionate harvest of higher volume old-growth stands. VPOP Response specifically recommended (p. 9) that "it is necessary to defer logging and road building in volume class 6 and 7 old-growth forest (as determined by field reconnaissance) below 800 feet elevation until a biological survey is completed." The Forest Plan Revision IDT recognized the concern for higher volume stands and took a broader approach toward protecting larger reserves and intact landscapes, which necessarily include higher volume stands. The IDT did not believe that a focus on protecting small isolated stands of the former volume class 6 and 7 that may be imbedded within a mosaic of clearcuts, susceptible to windthrow, was a prudent management approach to addressing conservation of old-growth associated species.

The final component of the reserve strategy addresses potentially endemic taxa (species or sub-species) that may exist on small islands. MacDonald and Cook (1994) reported 27 mammalian taxa endemic to Southeast Alaska. Many may have limited dispersal capabilities and are restricted to individual islands (e.g., Coronation Island vole); some may also be susceptible to loss and fragmentation of old-growth habitat. Populations existing on small islands (oceanic or habitat fragments) are more susceptible to local extinction (Wilcove et al. 1986, Burkey 1995). The archipelago of Southeast Alaska contains over 22,000 islands (Iverson 1996b) and uncertain but likely high levels of biotic endemism (MacDonald and Cook 1994). Lidicker (in Kiester and Eckhardt, 1994, p. 91) identified a concern for small island endemic taxa and recommended that no logging occur on islands of less than 1,000 acres to reduce risks to these taxa, and further recommended that at least one reserve be maintained on larger islands. The Other Mammal Assessment Panel expressed similar concerns relative to endemic taxa (Julin 1996).

In response to these concerns about endemic taxa with possibly unique gene pools that may be restricted to small islands, the Forest Plan protected all islands less than 1,000 acres from additional harvest of old-growth forest, in direct response to the Lidicker recommendation and concern expressed by the Other Mammal Assessment Panel.

2.2.2. Matrix Management

The second component of the old-growth forest habitat conservation strategy is management of the area outside reserves (the “matrix”) that is subject to timber harvest. This topic was of notable concern to the Pacific Northwest Research Station Review scientists who suggested that more attention be directed to this component of landscape conservation planning. They particularly noted the need to provide enhanced landscape connectivity and to manage human disturbance of the land similar to natural disturbance regimes (Kiester and Eckhardt 1994: Hansen p. 52; Lande p. 82; Lidicker p. 87; McCullough p. 109; McClellan p. 133).

Some management protections within the matrix are spatially explicit, such as the 1,000-foot beach and estuary fringe, and the riparian buffers for maintaining the integrity of the aquatic and riparian ecosystems. In addition, other forest-wide standards and guidelines preclude or significantly limit timber harvest in areas of high hazard soils, steep slopes, karst terrain, visually sensitive travel routes and use areas, and in timber stands technically not feasible to harvest. Finally, a number of species-specific standards and guidelines provide additional protection to old growth within the matrix.

2.2.2.1. Beach/Estuary Fringe and Riparian Habitats

Beach and estuary fringe, and riparian habitats, have special importance as components of old-growth forests, serving as wildlife travel corridors, providing unique wildlife habitats, and providing a forest interface with marine or riverine influences that may distinguish them as separate ecosystems within the larger old-growth forest ecosystem. Riparian areas are important for fisheries in providing, among other resources, the source of large woody debris that creates pools for rearing habitat, and in controlling stream temperatures and the amount of sediment reaching streams. Riparian areas provide habitat for terrestrial species associated with aquatic environments (amphibians, for instance, or mammals such as river otter and beaver), and for terrestrial species for which fish from streams are important food (brown and black bears). Considering the dendritic nature of riparian systems that begin high in watersheds, these riparian areas provide forested corridors connecting higher elevation regions in upper watersheds with lower elevation forests in valley bottoms. Riparian areas often contain plant species which can live only where water is available year-round. Riparian soils often support large spruce trees and some of the most highly-productive stands of old growth.

The beach fringe, the forested area adjacent to salt-water shorelines, is thought to be an important wildlife travel corridor, a transition zone between interior forest and salt water influences, and a unique habitat (or micro-climate) in itself. The beach fringe is a very important feature on the Tongass given the extensive amount of shoreline (more than 13,000 miles) that exists on the more than 22,000 islands. The beach fringe provides horizontal or low-elevation connectivity between watersheds, many of which otherwise have very steep sides and/or non-forested ridgetops. In conjunction with riparian areas, which provide connectivity within watersheds, the beach fringe is thought to be a component of the major travel corridor system used by many resident wildlife species.

Interagency habitat capability models developed previously for management indicator species of the Tongass produced the highest habitat suitability value in POG forests within the 500-foot beach fringe zone for the bald eagle, marten, and river otter (Suring 1993). The beach fringe was rated second only to the 1,000-foot estuary fringe for brown and black bears in overall habitat quality, and higher deer habitat values generally occur in high-volume old growth below 800-foot elevation, much of which occurs in the beach zone with a moderating maritime-influenced microclimate. A revised marten habitat capability model rated the beach fringe old-growth forests highest among all habitat components (Flynn 1995).

There are indications that the value of the beach zone habitat may extend beyond 500 feet. Gende et al. (1998) reported reduced bald eagle nesting densities and success in landscapes adjacent to clearcuts and recommended a beach buffer zone of at least 1,000 feet. The 1,000-foot beach fringe was also used frequently by radio-marked goshawks (Iverson et al. 1996). The importance of the beach fringe zone has long been recognized, and was a component of the Retention Factor Method used in the 1979 Tongass Plan, as amended (USDA Forest Service, 1986) (specifically recognizing the importance of the 1,000-foot beach fringe for brown/black bear, 600-foot for furbearers, and 0.25 mile inland from the beach for deer winter range).

In developing the old-growth forest habitat strategy, the information described above and the available literature relative to Southeast Alaska were carefully examined. The Forest Plan Revision IDT concluded that explicit corridors should be a component of a landscape conservation strategy, that a 1,000-foot beach and estuary fringe corridor was clearly justified by the available information but that no evidence supported a 3,300-foot buffer recommended by the VPOP Response. The IDT further reasoned that a 1,000-foot no-harvest beach and estuary fringe corridor was comparable or possibly superior to a 3,300-foot corridor that permitted up to 25 percent volume removal in 5-acre patch cuts as recommended by the VPOP Response. Accordingly, the Forest Plan establishes a Beach and Estuary Fringe Forest-wide Standard and Guideline that prevents timber harvest within 1,000 feet inland from mean high tide. The 1,000-foot beach fringe serves many functions: providing more effective landscape linkages between habitat reserves, protecting long-term bald eagle habitat capability, buffering the primary beach fringe zone (0 to 500 feet) from windthrow (Hodges 1982, Harris 1989), maintaining a functional interior forest condition within the entire primary beach fringe (Concannon 1995), and sustaining very important habitat for goshawks (Iverson et al. 1996).

In addition, the Forest Plan incorporated, as a minimum, the riparian habitat recommendations in the Anadromous Fish Habitat Assessment (AFHA 1995). Riparian habitat buffers also provide elevational corridors within forested watersheds. Mapping the small old-growth habitat reserves (see above) also provides additional landscape connectivity. Together, the beach and riparian habitat management features and the mapping of small reserves represented a substantial response to the landscape linkage element of conservation planning and significantly contributed to management of the overall matrix among habitat reserves.

2.2.2.2. Landscape Connectivity Standard and Guideline

The Forest Plan contains a standard and guideline that provides for the maintenance of a contiguous forested corridor, where it exists, connecting each large or medium habitat reserve to at least one other reserve. This standard and guideline is to be implemented during the environmental analysis for projects proposing to harvest timber, construct roads, or otherwise significantly alter vegetative cover. In addition, young-growth treatments to accelerate old growth characteristics to help increase connectivity for wildlife are encouraged.

2.2.2.3. Species-Specific Standards and Guidelines

A variety of species-specific standards and guidelines were adopted to strengthen the conservation strategy for individual species and species groups. Many of these have positive effects for a variety of old-growth-associated species. For some species, like the northern goshawk and the American marten, additional habitat conservation measures were prescribed in areas of the Forest where intensive timber harvest had occurred.

Stand level habitat management objectives, that contributed to maintaining features of old-growth forest within the matrix, were established in the 1997 Forest Plan Revision to reduce the adverse effects of clearcut timber harvest on marten and goshawk habitat use by retaining important forest structure during harvest. These habitat management measures were added to the Forest Plan in response to panel assessments (see Section III.B). In the North and Central Prince of Wales Biogeographic province, where risks of sustaining habitat for goshawks was greatest (Iverson et al. 1996), the 1997 Forest Plan Revision standards and guidelines provide for the retention of forest structure during harvest in VCUs where over 33 percent of the original POG has been harvested and harvest units are over 2 acres. This management standard and guidelines maintains an average of at least 30 percent canopy closure after harvest and requires that an average of at least 8 large (20 to 30 inches diameter at breast height [DBH]) trees/acre are retained at harvest. The objective of this provision was to retain some foraging habitat value after harvest; silvicultural prescriptions that provide for retention were considered to be superior to clearcut harvest (Iverson et al. 1996).

Similar stand level structural retention standards and guidelines in the Forest Plan were established to manage high value marten habitat. These standards and guidelines applied to the five higher risk biogeographic provinces identified by VPOP (Suring et al. 1993, p. 41) (East Chichagof, Kupreanof/Mitkof, Etolin Island and Vicinity (except Zarembo), Revilladagado Island and Vicinity, and North and Central Prince of Wales Island). In VCUs within these provinces where over 33 percent of the original POG had been harvested, including additional future harvest, high value marten habitat was to be managed to retain important forest structure for marten. Harvest units over 2 acres in size in high value marten habitat (e.g., high volume timber strata and below 1,500 feet in elevation) retained after harvest: an average of over 30 percent canopy closure, an average of at least 8 large trees/acre (20 to 30 inches DBH), an average of at least 3 large decadent (20 to 30 inches DBH dead or dying trees) trees/acre, and an average of at least 3 pieces/acres of large (20 to 30 inches DBH) down logs. For all other VCUs within these five provinces, the following structure was retained in harvest units in high-value marten habitat: approximately 10 to 20 percent of original stand structure will be retained with an average of 4 large trees/acre (20 to 30 inches DBH), an average of 3 large decadent trees/acre (20 to 30 inches DBH), and an average of at least 3 pieces/acres of large (20 to 30 inches DBH) down logs.

For both the goshawk and marten stand management standards and guidelines above, harvest units under 2 acres did not need to maintain any of the prescribed amounts of forest stand structure. However, to provide for retention of important forest structure, the effective silvicultural rotation was increased to 200 years.

In addition, other fine-filter species-specific standards and guidelines contribute to the old-growth strategy. These include standards and guidelines for raptor nest habitat protection, wolf den protection, brown bear foraging habitat along certain streams, and others. The major species-specific standards and guidelines include:

- Brown Bear Foraging Habitat: Establish forested buffers, where available, of approximately 500 feet from the stream at sites where additional protective measures are needed to provide cover among brown bears while feeding, or between brown bears and humans.
- Heron and Raptor Nest Protection: Protect active rookeries and raptor nesting habitat with a forested 600-foot windfirm buffer, where available.
- Marbled Murrelet Nest Protection: Protect identified marbled murrelet nests with a 600-foot radius of undisturbed forest habitat.
- Wolf Dens: Maintain a 1,200-foot forested buffer, where available, around known active wolf dens.
- Mountain Goat Travel Corridors and Winter Habitat: Identify and maintain travel corridors between important seasonal sites. Where feasible, maintain important mountain goat winter habitat capability.

2.2.2.4. Other Non-Wildlife Standards and Guidelines

In addition, although the conservation strategy was designed without consideration of the contribution of standards and guidelines that restrict timber harvest to protect resources other than wildlife, there are many other standards and guidelines that restrict or limit timber harvest. These other Forest-wide standards and guidelines preclude or significantly limit timber harvest in areas of high hazard soils, steep slopes, karst terrain, visually sensitive travel routes and use areas, and in timber stands technically not feasible to harvest.

2.2.3. Analysis of the 1997 Old-Growth Strategy

Appendix N to the 1997 FEIS presented an analysis of the 1997 Old-Growth Strategy. This analysis documented the amount of habitat protection produced by the Forest Plan and compared it with the recommendations of VPOP and other recommendations. The following section summarizes this analysis (see Section IV.A.6 of Appendix N to the 1997 FEIS for the details).

2.2.3.1. Amount and Distribution of Old-Growth Forest

The analysis presented in Appendix N to the 1997 FEIS noted that the first and most prominent feature of the old-growth habitat strategy in the 1997 Forest Plan was the substantial amount of POG forest that is protected forest-wide in both the reserves and in the matrix areas that are allocated to timber management (70.1 percent in reserves and 19.0 percent in the matrix). A total of 84 percent of the POG that was present in 1954 was estimated to be present in 100 years assuming the maximum timber harvest levels per decade allowed in the 1997 Forest Plan. This is equivalent to an estimated 90 percent of existing POG.

Adequate distribution of old growth habitats, and not necessarily the forest-wide total amounts, was a principal element of the VPOP conservation strategy (Suring et al. 1993). The proportion of old-growth protected in reserves varied by biogeographic province, but ranged from 38 percent (Kupreanof/Mitkof Province) to 100 percent (Admiralty and West Chichagof Provinces). Within protected old-growth forests, all volume classes of POG were protected as well. High-volume old growth generally contains the largest trees and averages 35,000 board feet per acre (Julin and Caouette 1997). An average of 44 percent of the POG in reserves was estimated to be high volume, whereas 43 percent of the old growth forest-wide was high volume. The proportion of high-volume old growth in reserves in 18 of 21 provinces equaled or exceeded the proportion present in the province as a whole.

The 1997 Forest Plan exceeded the minimum strategy recommended by VPOP relative to sustaining viable wildlife populations. While fully integrating the large and medium VPOP HCAs and the mapping of the small reserves, the 1997 Forest Plan protected substantial additional POG forest to further reduce risks to wildlife viability and enhance protection of biological diversity. For comparison, reserves allocated in the Forest Plan with at least 5,000 contiguous acres of POG (the minimum POG requirement for VPOP medium HCAs) exceeded the amount recommended by VPOP by 147 percent forest-wide (Appendix 2 of Appendix N to the 1997 FEIS). Old-growth allocated to reserves exceeded the amount recommended by VPOP in 20 of 21 biogeographic provinces, ranging from 9 to 460 percent over VPOP recommendations. This comparison was conservative: it did not include old-growth forest in contiguous reserves with less than 5,000 acres of POG, and did not include the substantial old-growth forest that would remain in the matrix.

The old growth strategy was noted to contain at least one large contiguous reserve relative to the province size in each of the 21 biogeographic provinces across the Tongass to address large scale distribution of large OGRs (Appendix 5 of Appendix N to the 1997 FEIS). Seventeen of the 21 provinces have at least 1 very large reserve (e.g. over 180,000 contiguous acres). For example, in the North Central Prince of Wales Province, a contiguous reserve of 200,584 acres (Honker/Sarkar/Karta) was provided in the Forest Plan—5 times larger than a VPOP large HCA (40,000 acres). Two provinces had a large reserve exceeding 75,000 acres; the two remaining provinces were intermediate sized-islands or aggregates of smaller islands and had contiguous reserves of from 30 to 40,000 acres and virtually all federal lands within the province were in a reserve land allocation (Dall Island and Southern Outer Islands).

High-quality old-growth forest was mapped in the largest reserves as well. The proportion of high-volume old growth (used as one indirect measure of old-growth habitat quality) in the largest reserves was equal to or greater than the proportion of high-volume old growth throughout the province in 16 of 21 provinces forest-wide (Appendix 5, of Appendix N to the 1997 FEIS). Many of these reserves previously existed (e.g., Admiralty and Misty Fiords National Monuments), while others were explicitly created to achieve this objective (South and Central Prince of Wales Island, Kupreanof/Miktof and East Chichagof Island).

The comprehensive old-growth habitat strategy in the Forest Plan was also responsive to the Pacific Northwest Research Station Review recommendation to not further fragment existing blocks of high-volume old growth by incorporating many existing roadless areas in reserves. An average of 89 percent (range 55 to 100 percent in each of 21 biogeographic provinces) of the Tongass was roadless (Appendix 4), an indirect measure of unfragmented (from clearcut harvest) landscapes. An average of 84 percent of the roadless acreage on the Tongass was allocated to “non-development” LUDs in the 1997 Forest Plan and would, thus, retain the roadless and unfragmented character of the landscape. A substantial portion of the Tongass would remain roadless and unfragmented in the Forest Plan

Additional concerns regarding habitat fragmentation were expressed by the VPOP Response that recommended that the three largest old-growth forest patches within each ecological province should be protected from logging and roadbuilding. An examination of how well the old-growth strategy in the Forest Plan responded to these general recommendations to maintain large blocks of old-growth forest was conducted. However, it was noted that there are various ways to define forest blocks or “patches”. Without some patch definition restrictions, virtually all old-growth forest on any island could be considered one contiguous and interconnected patch.

Two analyses were conducted to examine the recommendation regarding preservation of large blocks of old-growth forest. The first examined the concept of contiguous blocks of interior old-growth forest. Interior forest was defined as greater than 300 feet into the forest from the productive/nonproductive forest edge. The resulting five largest interior forest blocks in each biogeographic province were compared to the Forest Plan land allocations to determine the proportion of these blocks protected in a reserve. Forest-wide, 73 percent of the area of these five largest interior old-growth blocks was protected for a total of 476,000 acres (Appendix 6 to Appendix N of the 1997 FEIS). A small portion of these acres may no longer meet the definition of interior forest acres after the maximum timber harvest levels allowed in of the Forest Plan for 100 years are harvested. The proportion varied by province, from 38 percent protected in the East Baranof Biogeographic Province to 100 percent on West Chichagof, Admiralty, and North and South Misty Fiords Biogeographic Provinces.

A second analysis examined the largest contiguous blocks of only high volume old-growth forest and the proportion protected in reserves in the Forest Plan. Overall, within a biogeographic province, these high-volume blocks were much smaller than the interior forest blocks of all POG (Appendix 6 and Appendix 7 to Appendix N of the 1997 FEIS). Forest-wide, an average of 83 percent (province range: 36 to 100 percent) of the five largest contiguous high-volume blocks in each province was protected in reserves for a total of 225,000 acres (Appendix 6 to Appendix N of the 1997 FEIS). These first two methods of many possible delineations of “large blocks” provided somewhat different results. There was no analysis to support the “three largest old-growth forest patches” recommendation—certainly nothing compared to the in-depth analysis VPOP contributed in their initial conservation strategy (278 pp.) or the scientific reviews provided by the Pacific Northwest Research Station Review 18 scientists (282 pp.). Nonetheless, the Forest Plan provides substantial (73 to 83 percent) protection to old-growth blocks considered in this analysis.

Regarding the matrix, it was noted that the allocation of forest stands and landscapes to some form of timber harvest did not mean that all trees and stands would be harvested leaving only a continuous “sea of second growth.” There are numerous standards and guidelines limiting timber harvest in these matrix lands to protect specific resource and landscape components. An average of at least 57 percent (Appendix 8 to Appendix N of the 1997 FEIS) of the original (pre-1954) POG in these landscapes (the three timber harvest LUDs) would not be harvested and would remain standing throughout the planning horizon of 100 years, even with application of the maximum allowable timber harvest under the Forest Plan. A total of 69 percent of all existing POG in the matrix would remain after full plan implementation.

The relative quality of habitat within the three principal features of the matrix, the beach and estuary fringe, riparian habitat management areas, and other lands not available for timber harvest, are identified at both the province and VCU spatial scales. The beach and estuary fringe accounted for 15 percent of the POG protected in the matrix; riparian habitat accounted for about 24 percent, and the “other lands” accounted for the remaining 61 percent. As discussed earlier, the proportion of high-volume old growth was one measure of habitat quality: the beach fringe averaged 45 percent and the riparian areas averaged 43 percent high-volume old-growth forest.

2.2.3.2. Island Effects

The potential risk to island endemic species that may be closely associated with old-growth forests was evaluated by conducting an analysis of islands of varying sizes (Iverson 1996b). This evaluation revealed a very low risk to islands ranging in size from 1,000 to 10,000-acres in Southeast Alaska. It was noted that there are 58 islands of this size range, but only 8 had POG forest that was suitable for timber harvest in the Forest Plan representing only 2.2 percent of the POG on these islands (Table D-1). However, long-term risk may be elevated on some of these 8 islands considering past as well as potential additional harvest (e.g., Shelikof, Sokolof, Marble, and Orr Islands).

Risks were slightly higher for islands ranging from 10,000 to 100,000 acres, with 7 of 19 having suitable POG potentially available for harvest. Heceta Island was identified as the largest island in this category (41,000 acres of federal land) with POG suitable for timber harvest. Several of these islands could also have elevated risks due to the cumulative effects of past as well as potential additional harvest (e.g., Tuxekan, Catherine, Suemez, and Heceta Islands. However, most POG (92 percent) and most scheduled for timber harvest (95 percent) occurs on the largest islands exceeding 100,000 acres. The Forest Plan wouldl not add additional risk to islands under 1,000 acres and would minimize risks to islands under 50,000 acres, with a cumulative maximum of 2,100 acres of old-growth forest that may be harvested over the next 100 years. This analysis assumed maximum allowable harvest every decade for 100 years under the Forest Plan. Furthermore, the analysis assumed a potential harvest of nearly 600,000 acres of POG, whereas only 474,000 acres are actually scheduled for potential harvest.

In recognition of the uncertainty about island endemic species and their vulnerability, the Forest Plan contained a “survey and manage” standard and guideline designed to substantially reduce the risk to endemic mammals on these islands. If surveys indicate the presence of these taxa, proposed projects would be designed to ensure their long-term persistence on the island.

Table D-1.
Analysis of the Range of Island Sizes across the Tongass National Forest and the Amount of Productive Old-Growth at Potential Risk (in 1997)[1,2]

Island Size[3] (acres)	No. of Islands	Total Area	Total POG	No. Islands w/POG Suitable for Harvest	Acres POG	% POG	1995 Second Growth
1 to 1,000	461	68,807	43,201	0	0	0	3,660
1,001 to 10,000	58	196,503	95,647	8	2,105	2.2	13,659
10,001 to 100,000	19	502,271	272,552	7	25,759	9.5	29,710
Over 100,000	19	16,018,366	4,652,201	18	579,064	12.4	356,440
Total	**557**	**16,785,947**	**5,063,601**	**33**	**606,928[(4)]**	**12.0**	**403,469**

1 From Table 7 in Appendix N to the 1997 Forest Plan FEIS.
2 The proportion of the POG that is suitable for timber harvest over the next 100 years in the Forest Plan is a measure of relative risk to potential island endemic taxa that may be associated with old-growth forests.
3 Includes only federal lands.
4 Only 474,000 (80 percent) of these suitable acres are scheduled for harvest over the 100-year planning period.

2.2.3.3. Habitat Connectivity

The analysis in Appendix N of the 1997 FEIS noted that there is general agreement among scientists that habitat connectivity is an important component of a landscape conservation strategy (Kiester and Eckhardt 1994, Lidicker 1995). There is, however, uncertainty regarding how connectivity should be achieved in an integrated conservation strategy: through explicitly designed corridors; by designing larger reserves thereby decreasing dispersal distances and facilitating population interchange; or by using an overall matrix management design (e.g., the “50-40-11” matrix prescription designed to provide marginal foraging habitat between reserves for dispersing northern spotted owls [Thomas et al. 1990]).

In light of the uncertainty regarding a variety of approaches to provide landscape connectivity, a further review and analysis was conducted by the 1997 Forest Plan IDT. Thus, the 1997 Forest Plan incorporated a combination of all three landscape conservation design approaches to address landscape connectivity. It has not relied on a single strategy. Beach and riparian corridors of specific widths were established that provide significant within-island habitat connectivity; habitat reserves were enlarged (see Old-Growth Habitat Reserves above) often minimizing dispersal distances between many reserves; and standards and guidelines that govern management of the matrix outside reserves (including beach and riparian buffers) were partially designed to contribute to retaining a substantial old-growth forest component to provide connectivity. If site-specific project analyses identify deficiencies in landscape connectivity, the Forest Plan Old Growth Habitat LUD provided the opportunity to re-examine small habitat reserves, which may be adjusted to provide the necessary connectivity (see Small Old-Growth Habitat Reserves, below).

An additional approach to achieve landscape connectivity is to use timber harvest practices that retain some forest structure within the stand after harvest. Application of the marten and goshawk stand level management standard and guidelines was anticipated to contribute to maintenance of potentially important stand structure in landscapes with substantial amounts of even-aged clearcut harvest with little within-stand residual structure. The goshawk management standard and guideline was to be applied to the most heavily harvested and fragmented VCUs on Prince of Wales Island. The marten standard and guideline was to apply in the same VCUs plus additional VCUs in the North Central Prince of Wales, Revilla/Cleveland and Vicinity, East Chichagof, Mitkof/Kupreanof, and Etolin and Vicinity provinces. Since the marten standard and guideline applied to VCUs that currently exceeded 33 percent of POG harvested, as well as VCUs that would exceed that amount through future projects, this standard and guideline was anticipated to apply to additional VCUs in the future. Retention of these substantial amounts of within-stand structure served to minimize the adverse impacts of additional timber harvest.

Another feature of connectivity identified by the Pacific Northwest Research Station Review were critical links or “pinchpoints” connecting major landscapes within islands (Marcot in Kiester and Eckhardt 1994, p. 103). Such pinchpoints must be carefully protected (Kiester and Eckhardt 1994, p. 17). The 1997 Forest Plan IDT identified six such landscape pinchpoints, all relatively narrow areas between larger land units where future alterations in habitat could significantly reduce natural connectivity and limit the ability of land-based species to disperse or migrate. These areas and the degree of protection afforded by the 1997 Forest Plan at the time of its adoption include:

1. The portage between Tenakee Inlet and West Port Frederick on Chichagof Island is a narrow neck of land connecting northeast Chichagof Island to the main body of the rest of the island. This is in the East Chichagof biogeographic province. This area is completely protected with a large old-growth habitat reserve using the Old-Growth Habitat LUD.
2. The area connecting Lisianski Inlet with the North Arm of Peril Strait is a narrow region that connects two major portions of Chichagof Island. This area is fully protected as a Legislated LUD II area.
3. The area between Port Camden, Bay of Pillars, and Three-Mile Arm on Kuiu Island (Kuiu Island biogeographic province), a narrow neck of land connecting the northern and eastern part of the island to the rest of Kuiu Island. This area is protected with the Old-Growth Habitat LUD through a combination of several adjacent small old-growth habitat reserves.
4. The narrow area between Lindenburg Peninsula and the remainder of Kupreanof Island is largely protected by the Petersburg Creek Duncan Salt Chuck Wilderness. The remaining small area not included in the Wilderness between Portage Bay and Duncan Salt Chuck is primarily peatland; the 1,000-foot beach fringe provides additional connectivity.
5. The Neck Lake area between Whale Passage and El Capitan Passage on Prince of Wales Island (North Central Prince of Wales biogeographic province) has had significant past and on-going forest management activities. It also is a relatively narrow piece of land connecting the extreme northern end of Prince of Wales Island to the remainder of the island. A cross-island connection is nearly protected with a small reserve around Neck Lake and fully protected further south with

the very large natural setting reserve around Sarkar Lakes. Connectivity is also provided on both sides of the narrow pinchpoint with the 1,000-foot beach fringe corridor.

6. Sulzer Portage is between West Arm Cholmondeley Sound and Portage Bay at the head of Hetta Inlet on Prince of Wales Island. This relatively narrow neck of land joins the southeast part of Prince of Wales Island to the remainder of the island, connecting North Central and South Prince of Wales biogeographic provinces. This area has had considerable timber harvesting on both national forest and adjacent private lands. Due to a recent transfer of land ownership the area is now all private land, dividing the northcentral and south portions of Prince of Wales Island with a non-national forest strip 1 to 2 miles wide. Continued timber harvesting is anticipated on these private lands, with the potential of creating dispersal barriers. However, clearcuts and advanced second growth forests (50 to 100 years old) are unlikely to create complete barriers to movement for deer, wolves, marten and squirrels or other species of concern.

2.2.3.4. Summary

In summary, the Appendix N analysis noted that the 1997 Forest Plan IDT concluded that the original VPOP strategy was a sound and effective landscape approach to address the long-term conservation of old-growth associated wildlife species. VPOP used a coarse filter conservation planning approach to develop a comprehensive, multi-scale landscape conservation strategy. They incorporated the entire community of old-growth associated species into their analysis and focused on those species with the greatest viability or distribution concerns in the development of their strategy. Additional scientific information, such as conservation assessments and recommendations contained in the Pacific Northwest Research Station Review, were incorporated into the Forest Plan to further strengthen the original VPOP strategy. The VPOP Response was considered as a brief “initial response” of some possible considerations that may have been integrated into a final report. While VPOP Response recommendations were not explicitly incorporated, many of the elements of the VPOP Response were addressed in concept in the Forest Plan (wider corridors, larger reserves, protection of high-volume old-growth, etc.).

The old-growth habitat conservation strategy in the 1997 Forest Plan was carefully crafted in response to these fundamental conservation planning documents. Based upon consideration of the best available information related to conservation planning, the Appendix N analysis concluded that the 1997 Forest Plan provided a sufficient amount and distribution of habitat to maintain viable populations of old-growth associated species after 100 years of Plan implementation. Due largely to uncertainty, the 1997 Forest Plan did not, however, represent a “no risk” conservation strategy; rather it represented a balance of wildlife conservation measures that consider the best available scientific information and reflect an acceptable level of risk for continued species viability.

2.3. Modifications to the Strategy between 1997 and 2007

Since 1997, there have been 24 project analyses that have modified small or medium OGR boundaries and adjacent LUDs (Table D-2). Overall, these changes have resulted in an increase in reserve area and an increase in the amount of POG included within reserves. The net result of these amendments is that the acres suitable for timber harvest have been reduced by approximately 16,000 (Table D-2). The 2007 Forest Plan (defined as the 1997 Forest Plan, as amended through 2007) reflects these changes.

In addition to these changes in OGR boundaries, a number of ownership adjustments and other slight LUD modifications have been made. The combined effect of these changes on the areas within reserves and the matrix is shown in Table D-3. This table shows that while the total area of the Forest decreased by about 110,000 acres, primarily due to land adjustments, the acreage of development LUDs decreased by 112,000 acres and the acreage within reserves increased by about 2,000 acres over the period 1997 through 2007.

Table D-2.
Summary of Changes in Suitable Acres due to Forest Plan Amendments that Produce the 2007 Forest Plan[1]

Project Name (acres)	Small or Medium OGR	Project Year	Non-dev to Dev LUD Suitable Acres	Dev to Non-dev LUD Suitable Acres	Net Change in Suitable Acres
Canal Hoya	Small	1998	0	151	-151
Chasina	Small	1998	0	78	-78
Cholmondeley	Small/Medium	2003	894	6,873	-5,979
Control Lake	Small	1998	446	142	+304
Couverden	Small	2005	0	790	-790

Table D-3.
Summary of Acreages in Reserves and Matrix under the 2007 and the 1997 versions of the Forest Plan

Alternative	Reserves: Old-Growth Habitat LUD	Reserves: Other Non-Development LUDs	Reserves: Total in Non-Development LUDs	Matrix	Total	Percent of Forest in Reserves
2007 Forest Plan[1/]	1,182,424	11,985,410	13,167,834	3,605,974	16,773,808	78.5%
1997 Forest Plan[2/]	1,131,059	12,034,860	13,165,919	3,717,081	16,883,000	78.0%

[1/] Based on the 2007 Forest Plan (defined as the 1997 Forest Plan, as amended through 2007) and Tongass GIS.
[2/] Based on 1997 Forest Plan table on p. 4-2 and Table 3-77 of 1997 FEIS.

Table D-4 summarizes the POG acreage in reserves and the matrix for the 2007 and 1997 versions of the Forest Plan. The 2007 acreage of POG within OGRs, including all non-development LUDs is 3,518,425, which represents 71.1 percent of all POG on the Forest (Table D-4). Within the matrix, there is an additional 925,051 acres of old growth (18.7 percent) that is protected within the Beach and Estuary Fringe, Riparian Management Areas, and other unsuitable areas. This estimate includes unsuitable areas that are not yet mapped (e.g., Riparian Management Areas along unmapped streams, unmapped unstable slopes, unmapped high vulnerability karst lands). Finally, there is an estimated 28,598 acres of

POG that is suitable, but would not be scheduled due to economics and other factors. As a result, the 2007 Forest Plan results in the protection of 90.3 percent of all existing POG on the Forest, assuming the full Allowable Sale Quantity (ASQ) is harvested each decade. Table D-4 also compares these acreages and percentages with the same acreage categories in 1997, at the time that the Forest Plan Revision was adopted.

The maximum percentages that could be harvested are similar between the 1997 Forest Plan and the 2007 Forest Plan when one looks at only the larger POG types. Under the 2008 Forest Plan, a total of 71.3 percent of the high-volume POG (SD Model types 5N, 5S, and 67) and 67.8 percent of the big-tree POG (SD Model type 67) would be included within reserves. Overall, 88.9 percent of the existing high-volume POG and 88.6 percent of the big-tree POG would not be harvested.

Table D-4.
Summary of Productive Old-Growth Acreage in Reserves, Protected in the Matrix, and Suitable for Timber Harvest in 2008

Year	POG Area in Reserves	Matrix POG Protected or Not Scheduled for Harvest	Matrix POG Suitable and Scheduled for Harvest (represents the maximum POG to be harvested)	Total Existing POG[1/]
2007 Forest Plan[2/] (acres)	3,518,425	970,176	462,556	4,951,156
2007 Forest Plan[2/] (percent)	71.1%	19.6%	9.3%	100.0%
1997 Forest Plan (acres)	3,551,482	1,038,492	473,597	5,063,571[2/]
1997 Forest Plan (percent)	70.1%	20.5%	9.4%	100.0%

[1/] Note that the Tongass land base has changed since 1997 due to land adjustments and harvest has occurred.
[2/] The 2007 Forest Plan is defined as the 1997 Forest Plan, as amended through 2007.

2.4. New Relevant Science since 1997

This section describes new information related to conservation planning and science developed since 1997. It summarizes general information on conservation strategies, as well as species-specific information that are particularly relevant to the Tongass Conservation Strategy.

2.4.1. Conservation Strategies

2.4.1.1. General

Haufler (2006) conducted a comprehensive review of conservation science produced since 1997 and its relationship to the Tongass Forest Plan. In his review, he described major types of conservation strategies, as well as concepts that form the basis for those strategies (e.g., landscape ecology, corridors and landscape linkages, and habitat loss and fragmentation) and related new science (new science related to population viability was also addressed but is summarized in Section 3.0), and related these to the science behind the Tongass Conservation Strategy. This effort included a review of recent literature as well as recently completed and on-going conservation initiatives to identify approaches and strategies used by agencies and other organizations in their conservation planning efforts. This section provides a summary of that review.

The term “conservation strategy” refers to the framework and the underlying basis and assumptions used in planning to maintain or enhance biological diversity (Haufler 2006). Most conservation strategies share the common objective of conserving biodiversity, which has been succinctly defined by the United Nations Environment Programme (1991) as: “the variety of and variability within and among living organisms and the ecological complexes of which they are part; this includes diversity within species, between species, and of ecosystems.” To do so, the concepts of representation (i.e., addressing the range of environmental conditions in the planning area), resiliency (i.e., being capable of withstanding natural and human-caused changes in the environment), and redundancy (i.e., consisting of a sufficient number of areas to withstand larger scale stochastic events) have been emphasized as being important in delineating effective reserve designs (Shaffer and Stein 2000).

Conservation strategies can be distinguished based on whether they take a coarse filter or fine filter approach to conserving biodiversity. Coarse filter strategies focus on ecological communities or functional ecosystems where planning incorporates an appropriate mix of ecosystems that will maintain or enhance biological diversity and ecosystem integrity within a landscape (Haufler 2006). Recent approaches that form the basis of coarse filter strategies include the habitat diversity approach (i.e., maintaining or restoring adequate amounts of existing vegetation communities; Groves (2003), the historical reference approach (i.e., prioritizing conservation efforts based on a comparison of existing and historical conditions; Haufler 2000, Poiani et al. 2000), and the historic range of variability approach (i.e., maintaining the landscape within the historic ranges of variability; Aplet and Keeton 1999). However, there is little agreement on how to apply coarse filter approaches, with few examples of well designed coarse filter initiatives.

In contrast, fine filter conservation strategies focuses on species or groupings of species to address the ecological objective of maintaining the species or groupings of species within a landscape. Fine filter approaches include the use of umbrella species, indicator species, keystone species, flagship species, ecological engineers, focal species, declining species, at-risk species to represent other, co-occurring species. Groves (2003) and Noon and Dale (2002) provide an overview of these species-specific approaches. Under a fine filter strategy conservation areas are often identified using indices such as species richness, species diversity, or are based on biological hotspots, with the objective of protecting the maximum number of species (Chaplin et al. 2000). However, there is generally poor support in the literature for the fine filter approach because of the difficulty in identifying appropriate species to serve as surrogates, or whether this is even possible (Carignan and Villard 2002), and the inability of this approach to adequately represent all levels of biodiversity (e.g., landscape and ecosystem levels; Schwartz 1999, Chaplin et al. 2000, Groves 2003).

A central element in conservation planning, as indicated above under the two basic frameworks for conservation strategies, is the identification of conservation areas such as reserves or reserve networks. Conservation strategies may differ in their view of conservation areas, with some placing priority on their protected status (e.g., wilderness) such that they are kept separate from human influence (i.e., a compositionalism viewpoint; Callicott et al. 1999), with others emphasizing the functional capabilities of protected areas which may include working landscapes (the functionalism view; Callicott et al. 1999; Haufler et al. 1990, 2000). Though the latter view recognizes that reserves are an important tool for conserving biodiversity, it strives to balance human and conservation needs and focuses on providing functional ecosystems.

Another element that distinguishes conservation strategies is their primary focus. That is, whether they are concerned with rare or declining species or ecosystems or with representation of all species or ecosystems (Haufler 2006). A rarity focus typically devotes funding and effort to the identification of rare or declining elements (e.g., old-growth forest) and the protection of these elements in reserves. A representation focus strives to maintain the full spectrum of ecosystem elements (i.e., all forest structural stages) in adequate amounts and distribution across the planning landscape.

Haufler (2006) noted that most conservation strategies combine many of the approaches described. This more comprehensive approach to conservation planning enables the testing of the effectiveness of each plan element (e.g., implementing a fine filter approach to test the effectiveness of the coarse filter approach; Haufler 1999, 2000) and also addresses the shortcomings of any one strategy or view point.

2.4.1.2. Landscape Ecology

Landscape ecology and the associated concepts of scale, landscape effects, and habitat networks, have also received considerable attention in recent literature and have become a fundamental part of conservation planning. At the landscape scale, the influence of spatial arrangements, amounts, and sizes of habitat patches in landscapes, and the relationships of these factors with ecological processes are important advances (Turner 2005, Freemark et al. 2002). Both the grain (patch-based versus landscape-based) and extent (delineation of planning areas) of landscape analyses have been identified as critical elements in conservation planning, as they influence the results and implications of modeling efforts (Bassett and Edwards 2003).

2.4.1.3. Landscape Linkages and Corridors

Since the 1990s, a common element of conservation planning has been to ensure that adequate connectivity between habitat reserves is maintained to facilitate movement across the landscape and thus exchange between populations. Traditionally, connectivity has been viewed in the form of structural, often linear, elements of the landscape (i.e., riparian buffers) that literally act as corridors through which species move between larger habitat patches within the surrounding matrix. However knowledge of species ecology and dispersal capabilities, coupled with new understanding of landscape ecology, has broadened this view to include linkage zones, or areas within the landscape that may not physically connected but include appropriate habitat elements that provide functional connectivity (Tischendorf and Fahrig 2000). Landscape linkages address movement capabilities, habitat patches, landscape configurations, matrix conditions, barriers, and their ability to maintain continuous populations (Haufler 2006).

2.4.1.4. Habitat Loss and Fragmentation

Numerous recent empirical studies have evaluated the effects of habitat loss and fragmentation on a variety of species. Results of these studies indicated that 1) habitat and fragmentation are not independent, with the degree of habitat fragmentation influencing the magnitude of direct effects from habitat loss (Goodsell and Connell 2002); 2) fragmentation and resulting distribution of remaining habitat is of primary concern in managed landscapes where there has already been substantial habitat loss/conversion (Freemark et al. 2002); 3) interior and specialist species, as well as those that are rare or isolated will be the most affected by habitat loss and fragmentation (Bender et al. 1998, Davies et al. 2000), 4) habitat conversion may benefit some species (McGarigal and McComb 1999); 5) the amount and configuration of remaining habitat were influential in the landscape occupancy (Villard et al. 1998, McIntyre and Wiens 1999, Radford 2005); 6) the quality of remaining habitat may be more important than the quantity (Braden et al. 1997). Notably, studies evaluating the effects of fragmentation in various landscapes indicated that some of the negative effects of fragmentation on vertebrates observed where ecosystems have been converted to urban or agricultural uses have not been found in landscapes where timber harvest is the primary land use (Freemark 2002)

Theoretical studies have also been conducted that provide some insight on how the effects of habitat loss may operate. With (1999) described two perspectives that have resulted from these efforts. One is based on the theory of island biogeography where the objective is to identify the appropriate distribution of habitat patches which are compared to island surrounded by a matrix of non-habitat. The other is based on landscape permeability and the ability of species to move through the landscape (dispersal abilities), and views that landscape as a mosaic consisting of a spatially complex variety of habitat conditions.

The issue of habitat adequacy, or the threshold at which the amount of remaining habitat is insufficient to facilitate species persistence, has also been the subject of recent research. Risks of extinction tend to display non-linear responses as the effects of habitat fragmentation increase (With and King 1999, Flather et al. 2002). Under theoretical studies, threshold effects of habitat loss have been noted at 60 to 80 percent (Flather et al. 2002, Fahrig 1997). However, empirical studies have found the adequacy question difficult to isolate because of complexities in landscape mosaics, matrix conditions, temporal changes, and the various habitat needs of different species. Empirical studies note species losses typically above a 90 percent threshold (Radford and Bennett 2004, Virkkala and Toivnen 1999).

2.4.1.5. Relationship to the Tongass Conservation Plan

The conservation strategy was described as a "habitat-based wildlife conservation strategy that employed old-growth associated umbrella species to design a coarse filter/fine filter approach for species conservation" (Haufler 2006). Based on Haufler's (2006) review, the science underpinning the Tongass conservation strategy is supported by recent literature. New information suggests that additional consideration of windthrow effects, which may occur at greater magnitudes than once thought (Kramer et al. 2001) and have farther reaching effects on habitat selection of some species (DeGayner et al. 2005), and a finer scale analysis of the distribution of plant associations (e.g., VanHees and Mead 2005) may be warranted to enhance the existing coarse filter component of the conservation strategy (Haufler 2006). At this time, plant association mapping for the Tongass does not exist, and the development of such mapping would be an enormously expensive undertaking. In lieu of evaluating how representative are the reserves based on plant associations, ecological subsection and biogeographic province mapping was used in conjunction with old-growth types as a surrogate. Likewise, a finer-scale assessment of viability for some species, particularly endemics (see *Wildlife* section for discussion of new science related to endemism on the Tongass) may be warranted to ensure the coarse filter component of the conservation strategy is meeting the needs of all species, including those that are rare or occupy limited distributions (Haufler 2006). However, Haufler (2006) concluded that "the developments in the field of conservation science produced since 1996 indicate that the conservation strategies used in the plan are still valid at the present."

In April 2006, an Interagency Conservation Strategy Review workshop was held to review the Tongass Land Management Plan conservation strategy in light of new information since 1997 (USDA Forest Service 2007). The objectives of the workshop were to:

1. Facilitate robust discussion between an interagency workgroup and invited scientific and technical experts regarding new information attained since 1997 that may be relevant to the conservation strategy; and
2. Generate and discuss science-informed "Considerations" relative to the strategy."

Considerations included identification of the need to attain additional information or conduct additional analysis regarding a scientific question or issue, the need for change to the conservation strategy, or other investments or work. The workshop included technical presentations regarding recent and current studies on species and species groups of concern on the Tongass. A broad conclusion of the workshop was that the conservation strategy continues to be supported by science (USDA Forest Service 2007). Although the information presented emphasized that there is still uncertainty associated with managing wildlife habitat on the Tongass, the new information presented has increased our knowledge of species/habitat relationships, reinforced the idea that retaining old growth in a system of Forest-wide reserves is appropriate for many species, and reiterated that having a very conservative approach to conservation of old-growth-associated species is still warranted and supported by science.

2.4.2. Species-Specific Science

This section presents a summary of the new information for individual species that is relevant to the Tongass Conservation Strategy, with focus on those species that are directly relevant to proposed changes to the Conservation Strategy. The majority of this information was presented at the April 2006 Interagency Conservation Strategy Review workshop and is summarized in a report (USDA Forest Service 2007). Reference to this information, as well as more complete discussion of this new information, can be found throughout the *Wildlife* section in Chapter 3 of the FEIS. This section summarizes the key highlights of information with particular focus on goshawk and marten, since these two species have specific standards and guidelines amended.

2.4.2.1. Northern Goshawk (including the Queen Charlotte goshawk subspecies)

The results of 10 years of research on the Queen Charlotte goshawk in Southeast Alaska were summarized at the Conservation Strategy workshop (Flatten et al. 2001,2002; Lewis 2005; Lewis et al. 2001, 2006). This research was in various studies, some of which is published and some of which is available in agency reports. A total of 69 adult goshawks (37 females and 32 males) were radiotagged from 1992 to 2001. Using 2-year and 1-year tags on females and males, respectively, greater than 2,800 relocations were recorded over approximately 500 km^2 of the Tongass National Forest.

Nest trees are typically found in the largest trees available relative to the nest stand. Basal area was higher at the nest tree (> 60 percent) than the surrounding stand (< 60 percent). Aerial photo analysis also showed a difference between the amount of forest, productive forest, and canopy cover at the nest site versus random sites; however, although it was statistically significant, it may not be biologically significant. Eighty-nine percent of the 63 nest sites evaluated had multi-storied canopies.

Two large spatial scales (816 ha and 2,088 ha) were used to provide a summary of the vegetation surrounding 78 known nest sites based on GIS analyses. POG on NFS land represented 37 to 40 percent of the circular areas around these nest sites on average, followed by unproductive forest on NFS land at 24 percent, and NFS young growth at 9 to 10 percent. Nonforest on NFS land made up 5 percent and non-NFS land and saltwater made up the remaining 23 to 25 percent (see EIS planning record). Sixty-eight to 70 percent of the POG on NFS land inside the circles was protected in reserves or in the matrix. Use by adult males and females during the nesting and non-nesting season showed a consistently higher use of POG forest in proportion to availability. Habitat use of the 1,000-foot beach and estuary buffer was higher for females than for males during nesting and non-nesting seasons and peaked again at approximately 3,000, and 4,000 feet from the beach fringe.

Using the same approach discussed above, a hypothetical post-fledging area (PFA) was developed using a radius centered on a nest site and determined by the mean distance moved by northern goshawk juveniles (approximately 1,500 m) from the nest. Based on habitat categories of suitable (medium- and high-volume old growth), low-volume old growth, harvested, and nonproductive forest, approximately 45 percent of the mean PFA was in nonproductive forest, followed by suitable habitat (39 percent), low-volume old growth (8 percent), and harvested (4 percent). Results of this hypothetical PFA analysis indicate that about 40 percent of the PFA on average will be medium- or high-volume POG, of which 55 percent was in a Timber LUD or non-NFS lands.

Adult goshawk home ranges were large, much larger than most other home ranges documented in North America. Median home range sizes ranged from 3,900 ha to 11,800 ha for adult females during the nesting and non-nesting season, respectively. Male home ranges were slightly larger in size ranging from 4,300 ha to 11,900 ha during the nesting and non-nesting seasons, respectively.

Movements by nesting pairs within a territory between year 1 and year 2 ranged from 0.1 to 3.2 km with the majority (67 percent) moving less than 0.4 km. Female goshawks tend to move much greater distances between nests in sequential years than males with approximately 35 percent of females leaving their nesting area, re-pair, and nest in a new area the next year. However, of 24 nesting territories, 54 percent remained within 0.36 km radius of the previous years nest and all movements were within 3.2 km of the nest site. Nesting pairs split up more often and between-year nesting dispersal of adult female goshawks is much higher than anywhere else they have been studied in detail in North America.

The diet of goshawks in Southeast Alaska is dominated by a few key prey (grouse, medium-sized birds, and red squirrels, where present). Prey rich areas include the northern half of the Tongass National Forest, where blue grouse and red squirrel are the dominant prey items taken. On Prince of Wales Island (POW) and other islands where sooty grouse and red squirrel are not present, spruce grouse, Steller's jay, and ptarmigan are the dominant prey items taken. Small mammals make up a small portion of the overall diet in this area. Ten nests were monitored as part of the study and of all food deliveries to the nest, 78 percent of the goshawk diet in Southeast Alaska consisted of bird species, with grouse the most commonly delivered prey item. From a broader diet pattern using stable isotope and prey associations, forest-dwelling prey items are, not surprisingly, dominant, but there is also a component of tidal and wetland prey species in their diet.

Recent studies confirm the importance of management for prey in relation to goshawk productivity (Kenward 2007). Salafsky et al. (2007) recommend that goshawk management strategies incorporate forest management practices that increase the abundance and diversity of available prey resources. The differences in prey species abundance and distribution across the Tongass may help explain some of the variation in productivity, territory size and nest site selection (Lewis et al. 2006, see also compiled information in U.S. Fish and Wildlife Service 2007).

In a review of over 180 publications on goshawk habitat relationships, Reynolds (2004) reported that, although goshawks predominantly nest in mature and old-growth forest characterized by closed-canopy stands of large, dense trees, there is considerable variation in nest sites among populations, with goshawks in Oregon and Nevada nesting in stands with canopy cover as low as 31 percent. Reynolds (2004) also reported that outside of the nesting season, the variation in habitats used by goshawks is even greater (multiple forest age classes, edges, and openings) and is apparently related to differences among habitat in prey abundance and availability (i.e., goshawks may nest or forage more often in habitat where prey is more abundant). Reynolds (2004) concluded that the main factors limiting goshawks were habitat structure for both nesting and foraging (rather than composition) and prey. This idea was also demonstrated by Reynolds et al (1992) who used a food web-based, ecological approach to develop forest management recommendations for goshawks in the Southwest United States. Taking into account both goshawk habitat requirements and the habitat requirements of 14 of their prey species, Reynolds et al. (1992) recommended that no more than 60 percent of a desired landscape of goshawk and prey habitats consist of mature to old-growth forests, and that post-fledging family areas (i.e., the area immediately surrounding the nesting area) should include habitat attributes important to prey species, including snags, downed logs, woody debris, large trees, openings with herbaceous and shrubby understories, and an intermixing of forest vegetative stages. Reynolds et al. (2006) concluded that management prescriptions based on the ecology (e.g., composition, structure, pattern, and dynamics) of a forest ecosystem, is a more appropriate basis for developing desired forest conditions that support goshawks and their prey.

Management recommendations for goshawks have been incorporated into multiple Forest Plans across the United States. Many of these are based on Reynolds et al. (1992), which includes recommendations for goshawk habitat for a variety of spatial scales, including nest sites and post-fledging family areas. These recommendations are specific to habitats in the southwestern United States, though they have been used in other geographic areas. While information from these studies regarding goshawk habitat relationships is useful across a broad geographic areas, specific recommendations for standards and guidelines is less useful. Because of significant differences in habitat and the extent of human influences on natural processes between Alaska and the Southwest, specific management prescriptions have limited applicability to Southeast Alaska.

In addition to these findings, limited new research has shown goshawk use of young-growth stands. Although POG is still considered the optimal nesting habitat for this species, non-productive forest types and second-growth stands are also used by goshawks for movement and foraging (and sometimes nesting), emphasizing the importance of matrix lands in goshawk management (McClaren 2004, Boyce et al. 2006, Reynolds et al. 2006). Some nests have been found in maturing second-growth (previously harvested) stands (Bosakowski et al. 1999, McClaren 2003). On Vancouver Island, most second-growth stands supporting nests were 60 to 80 years old, and suitable structure was apparently achieved in as little as 50 years (McClaren 2003). Additionally, Doyle (2004b) found that blue grouse, an important prey species for goshawks on the Queen Charlotte Islands, selected stands with more open canopies indicating that there may be a threshold below which timber harvest would not adversely affect grouse, or goshawks as their predators. On Douglas Island in Southeast Alaska, goshawks have been observed to nest in 80-90 year old stands (Kim Titus, Alaska Department of Fish and Game. pers. comm., 2007).

Management of the nest stands around known goshawk nests continues to be an important factor in goshawk conservation; some Forest Plans incorporate management of an area around the nest for fledglings (USDA Forest Service 2006). With respect to nest site management, Reynolds et al. (1992) recommended nest buffers of 30 acres, with maintenance of at least 3 known nests and 3 replacement nests (totaling 180 acres) within a 600 acre post-fledging family area. Thus, they recommend that 30 percent of the post-fledging family area should be retained for nesting habitat, with rest in a variety of successional stages. Management for goshawk nests is complicated by the difficulty in finding nests, particularly in the remote terrain of Southeast Alaska, where detection rates appear to be lower than in other areas (U.S. Fish and Wildlife Service 2007). Goshawks often have multiple alternate nests within a territory, which further complicates management of nest sites (USDA Forest Service 2007). Recent research in the southwestern U.S. confirms the difficultly in managing for goshawks only at the nest scale because detectability of goshawks is highly variable among individuals as a result of extensive year-to-year and spatial variation in breeding. Goshawks do not always nest every year, often skipping nesting for one or more years; this behavior is most likely due to prey abundance and availability (Reynolds et al. 2005).

2.4.2.2. American marten

Several new studies and concerns related to the conservation of marten were presented at the Interagency Conservation Strategy Review: An Assessment of New Information Since 1997 in April 2006 (USDA Forest Service 2007). Marten experts reviewed and summarized new information relevant to Tongass management issues. New information was presented relative to the level of endemism in marten on the Tongass. Preliminary molecular analyses distinguish two lineages of marten and indicate that they have very different evolutionary histories (Stone and Cook 2002, Small et al. 2003, Cook et al. 2006). The two lineages (*americana* and *caurina*) are considered by some to be two species, but have not been formally identified as such. The *caurina* lineage is known to inhabit only two islands within the archipelago (Admiralty and Kuiu Islands; Cook et al. 2006). There are two contact zones (i.e., zones where the lineages coincide) in North America, one in Southeast Alaska and one in Montana (Cook et al. 2006). In addition, there are records that marten were introduced on many islands in Southeast Alaska in including Prince of Wales, Baranof, Chichagof and nearby smaller islands (MacDonald and Cook 2007). The authors speculate that the endemic lineage of marten (*caurina*) may have occurred on more islands than Kuiu and Admirality and may have been extripated by introductions of *americana*.

Between 1990 and 1998, studies were conducted on Chichagof Island to assess marten habitat selection at multiple scales, demographics, diet, and prey availability. Results indicated that marten numbers fluctuated greatly over time in response to food availability and trapping mortality (Flynn et al. 2004). Habitat requirements reflect a strong interaction between food, cover, climate, and predation, with forest cover being particularly important for travel, dens and resting sites, hunting and avoiding predation, and staying dry. Martens selected forest stands with increasing amounts of structure (e.g., selected stands with a greater number of large trees and multiple stories); with stronger selection occurring in winter. Important habitat features included large logs and stumps in decay classes 4 and 5 and the bases of large live trees, which they use for dens and resting sites. Habitat data were consistent with the Forest Plan definition of high value marten habitat.

Several studies have indicated that marten are sensitive to fragmentation (Hargis et al. 1999, Flynn et al. 2004). Based on metapopulation theory, spatially isolated populations will persist in suitable habitats if regularly recolonized (Ruggiero et al. 1994).

To determine whether the results of the Chichagof Island studies were applicable across the Tongass, eight study areas in Southeast Alaska were established between 2001 and 2003, representing different marten populations (Flynn et al. 2004). Hypotheses include 1) marten abundance is greater than or equal to 25 marten per large OGR (which was an assumption for the Forest Plan Conservation Strategy) and 2) marten densities would be greater on areas with habitat composition similar to OGRs, but with more diverse and abundant food resources.

This study indicated that only the Chichagof Island site had abundance estimates of greater than 25 females per OGR and only the Point Couverden and Thomas Bay sites had upper confidence intervals greater than 25 females per OGR. A large variation in small mammal abundance was observed, with long-tailed voles only abundant on Chichagof Island, Keen's mice common except on the mainland, and red-backed voles occupying a limited distribution but numerous where they occurred (e.g., Etolin Island, Point Couverden, Thomas Bay, and Yakutat). Marten fed on long-tailed voles when they were available, and generally avoided Keen's mice and red-backed voles. However, when vole numbers were low, marten switched to salmon. Marten numbers were best predicted by long-tailed vole abundance (positive correlation) and Keen's mice abundance (negative correlation); red-backed voles were not a significant factor. The ungulate index was marginally significant and fragmentation indices were correlated with marten density.

Based on these results, marten experts at the Conservation Strategy Review concluded that the OGR system appears to be an appropriate model for marten conservation, though they felt that management needed to be tailored to specific island populations (Cook and McDonald 2001, Cook et al. 2001). They believe that OGRs may not provide enough habitat in themselves to maintain healthy populations and additional conservation measures may be necessary, such as managing matrix lands as productive habitat and maintaining corridors between OGRs (Flynn et al. 2004). Studies of marten home ranges have shown that they encompass areas of timber harvest and roads, elevating the importance of matrix management in providing functional connectivity across the landscape for marten (Flynn et al. 2004).

Studies on Mitkof Island indicated that martens selected for POG and used a wide variety of POG types but used some clearcuts 26 to 40 years of age; on Mitkof these clearcuts where characterized by abundant understory forage and small mammals (Flynn et al. 2004). Home ranges of marten were well distributed across the landscape and included areas with timber harvest and roads. Although they selected against it, they seemed to readily travel across areas of noncommercial forest as well as POG and clearcuts with established conifer cover. Prey quality and quantity appear to be very important in predicting marten abundance and distribution.

2.4.2.3. Other Species

Research has also identified new endemic species, and refuted species thought to be endemic. Regardless, changing the list of endemic species considered by the panel assessment would not change the fact that they occupy limited distributions and some are sensitive to habitat conversion related to timber harvest. However, new science is continuing to emphasize the importance of the Alexander Archipelago as a center for endemism from a global perspective (Cook and MacDonald 2001, Cook et al. 2006).

Recent research on small endemic mammals in Southeast Alaska has focused on documenting distribution and increasing information regarding genetic variation. There has been little work, except for marten and flying squirrel, directed at habitat relationships. Therefore, while we know more about endemic mammalian abundance and distribution across the Tongass, there is not much additional information to support significant changes to the Conservation Strategy for endemic mammals.

Recent analyses presented at the Tongass Conservation Strategy Review Workshop (2006) updated the relationship between road density and wolf mortality related to legal and illegal hunting and trapping. This analysis was based on a regression analysis of average wolf harvest by Wildlife Analysis Area (WAA) between 1990 and 1995 against total road density for lands below 370 m elevation. Results presented the probability of an overkill (average harvest of greater than 30 percent of the population) or destructive harvest (harvest greater than 90 percent of the population occurring once between 1985 and 1999) of the wolf population on Prince of Wales Island, taking into account road density and whether the road system was connected to a main road system with access to a ferry. Results indicated that the probability of overkill for WAAs with road density greater than 0.7 miles per square mile at 40 percent, if the WAA is connected to a main road system and 13 percent if not. Results also indicated that 32 percent of WAAs on Prince of Wales Island had road densities indicative of a high probability of overkill and 52 percent had road densities indicating a high probability of having had at least one destructive harvest between 1985 and 1999. These results indicated that roads exerted a strong influence on wolf mortality, particularly when connected to main road systems. However, it is important to note that roads themselves do not decrease habitat capability for wolves, but increased density of roads may lead to higher hunting and trapping mortality through improved human access. There are other methods available to address unsustainable hunting and trapping mortality including changes to both State and Federal hunting and trapping regulations and increased enforcement.

2.5. Modifications to the Strategy under 2008 Forest Plan Amendment

The comprehensive science-based conservation strategy included in the 1997 Forest Plan is a scientifically sound foundation from which to base management decisions. Its system of large, medium and small OGRs across the Forest was implicitly designed to assure well distributed, viable wildlife populations. Alternative 5 of the 2008 Forest Plan Amendment Final EIS maintains the 2007 Forest Plan (1997 Forest Plan, as amended through 2007) old-growth conservation strategy, as described in Sections 2.2 and 2.3. Alternatives 1, 2, 3, and 6 of the 2008 Forest Plan Amendment Final EIS retain the main components of the conservation strategy (i.e., the OGR system and non-development LUDs, the beach fringe, riparian buffers); in addition, they expand the areas within the Forest-wide reserve network and incorporate some modifications to the standards and guidelines. This section describes the differences between the 2007 Forest Plan's conservation strategy, as represented by Alternative 5, and the conservation strategy proposed under Alternatives 1, 2, 3, and 6.

Alternatives 4 and 7 differ from the other five alternatives in that they eliminate or modify significant portions of the conservation strategy and these are also addressed in this section and compared with Alternative 5 as well as the 1997 Forest Plan. Alternative 4 modifies the coarse filter component by identifying Old-Growth Habitat LUDs in only four of the most heavily modified biogeographic provinces (North Central Prince of Wales, Kupreanof/Mitkof Islands, Dall Island and Vicinity, and East Chichagof Island) in addition to maintaining two individual reserves including the Wright Lake (mainland southeast of Wrangell), and Myers Chuck (Cleveland Peninsula northwest of Ketchikan) reserves and creating one near Eva Lake (northeast Baranoff Island) in an area currently designated as Semi-Remote Recreation. In addition, all VCUs outside of these biogeographic provinces would be required to retain 33 percent of their old growth with no requirement to consider spacing, location, size, shape, or composition in the design of the retained acres, as is provided by the 2007 Forest Plan Old-Growth Habitat Reserve Criteria (see Section 2.2.1.2, *Description and Design Features of the Reserve Network*). As under all other alternatives, OGRs are also provided by other non-development LUDs, although, with the exception of Alternative 7, the acreage is less under Alternative 4 than under all other alternatives. Alternative 7 maintains substantial area in non-development LUDs, but entirely eliminates the Old-Growth Habitat LUD and would not have a specific retention requirement.

Of the other alternatives, Alternatives 1, 2 and 3 all have significantly less old-growth harvest as compared to Alternative 6. This Appendix therefore focuses on effects to Alternative 6 because this is the benchmark by which to measure effects to these three other alternatives. Adverse effects to wildlife would be less under Alternatives 1, 2 and 3 based on the volume of old growth projected to be harvested and this is fully discussed in the Wildlife Section of the FEIS.

2.5.1. Changes to Forest-wide Reserve Network (coarse-filter approach)

The Forest-wide Reserve network is expanded under Alternatives 1, 2, 3, and 6, relative to Alternative 5 (the 1997 Forest Plan Revision as amended). This expansion includes additional acreage in the Old-Growth Habitat LUDs relative to Alternative 5 and relative to the original 1997 Forest Plan. The expansion of the Old-Growth Habitat LUDs is the same for all four alternatives. In addition, the acreage in non-development LUDs is expanded for each of the four alternatives, with the amount of the expansion varying by alternative. As noted above, Alternative 4 identifies a smaller area than Alternative 1, 2, 3, 5, or 6 in Old-Growth Habitat LUDs and Alternative 7 does not identify any area.

2.5.1.1. Changes to Old-Growth Habitat LUDs

The original 1997 Plan noted that small OGRs had received less analysis and mapping precision than was necessary to meet the Plan standards. Large and medium OGRs received a rigorous review to be sure that they achieved the conservation strategy objectives (1997 Forest Plan, p. 3-82). However, the small OGRs received differing levels of reviews. Therefore, the Forest Plan and the Tongass National Forest Land and Resource Plan Implementation Policy Clarification (referred to as TPIT; USDA Forest Service 1998;) provided for the further evaluation and possible adjustment of the locations of small OGRs (USDA Forest Service 1997, Forest Plan, p. 3-82).

The 1997 Forest Plan standards and guidelines for OGRs state that during project level environmental analyses for project areas that include or are adjacent to a mapped OGR, the size, spacing and habitat composition of mapped reserves may be further evaluated (USDA Forest Service 1997, Forest Plan, p. 3-82). TPIT (USDA Forest Service 1998, p. 1) stated that an interagency team of biologists (referred to as the interagency team) would jointly evaluate the location and composition of the small OGR as mapped in the Forest Plan using criteria in Forest Plan Appendix K. The objective of the interagency team review described above was to develop a consensus biological recommendation on small reserve locations that was consistent with the Forest Plan. The Forest Service line officer retained decision authority to implement recommended changes or modify them. Because changes in OGRs resulted in a change in LUD, a Forest Plan amendment was required to implement changes.

As described in Section 2.3, analysis and mapping refinement of OGRs associated with 24 project areas has been conducted since 1997 (Table D-2). These adjustments were incorporated into the Forest Plan via non-significant Forest Plan amendments. Efforts to complete this higher level of analysis and mapping on all other small reserves have been ongoing since 1997. As part of the current Forest Plan Amendment process, the Forest worked with the Alaska Department of Fish and Game (hereafter referred to as ADFG) and the U. S. Fish and Wildlife Service (hereafter referred to as FWS) to complete a more comprehensive review and mapping effort. This process was conducted in 2006 and 2007 and included the development of a biological recommendation for adjustment of OGR boundaries, a refinement of that proposal with Forest Service Ranger District staff, and a further refinement by the Forest Supervisor. This refinement process was conducted in order to consider multiple-use objectives in addition to pure biological ones. The final proposal is included in Alternatives 1, 2, 3, and 6 of the Final EIS. Alternative 5 retains the 1997 Plan (as amended) reserve network and the reserves of Alternatives 4 and 7 are not affected by this proposal.

The final proposal for modifying small OGR boundaries was based on reviewing all small OGRs and a few medium reserves. As a result, OGR locations were generally finalized for all but 13 small OGRs. OGR locations are expected to change in the future only if a project occurs near these 13 reserves or under other limited circumstances (see Appendix K to the Final EIS). The net result of the review was an increase of 39,000 acres in the Old-Growth Habitat LUD, from 1,182,000 to 1,221,000. In addition to this expansion, some areas containing Old-Growth Habitat LUDs were converted to other non-development LUDs (e.g., Special Interest Area and Semi-Remote Recreation) and remain a part of the OGR network. These areas are discussed in the next subsection and the net result of all these changes is summarized in Section 2.5.1.3.

Not only was the total acres in the Old-Growth Habitat LUD increased, but the quality of the small OGRs was also improved. Updated local information was used, in many cases, to increase the protection of key old-growth species habitat, including known goshawk nests, important black bear, mountain goat and brown bear habitat, riparian habitat, anadromous streams and beach fringe. In addition, connectivity was another consideration in updated small OGRd locations. Rationale for making these adjustments were documented in an OGR tracking table for the refinement effort (located in the planning record).

2.5.1.2. Changes in Other Non-Development LUDs

The Old-Growth Habitat LUDs discussed in the previous subsection are a critical piece of the OGR network, but many other non-development LUDs represent important parts as well. Although the area in Old-Growth Habitat LUDs is the same for Alternatives 1, 2, 3, and 6, the total area in other non-development LUD categories varies. Alternatives 4, 5, and 7 vary in both their Old-Growth Habitat LUD and their other non-development LUD acreage. The acreage in many individual non-development LUD categories is constant regardless of the alternative (e.g., wilderness, LUD II, research natural area); however, the acreage in three non-development LUD categories (other than Old-Growth Habitat) differs among alternatives. These categories include: Special Interest Area, Semi-Remote Recreation, and Remote Recreation. Special Interest Area acreage was expanded by 47,000 acres relative to Alternative 5 (the 1997 Forest Plan, as amended), under Alternatives 1, 2, 3, 4, 6, and 7. The change in Semi-Remote and Remote Recreation acreages varies by alternative. For Alternative 6, the area in these two LUDs increased by 63,000 acres compared with Alternative 5. For Alternatives 1, 2, and 3, these LUD acreages increased by 2,681,000, 1,591,000, and 717,000 acres, respectively, while for Alternatives 4 and 7 the LUD acreages decreased by 379,000 and 308,000 acres, respectively.

The net increase in non-development LUD acreage (not counting the Old-Growth Habitat LUD) relative to Alternative 5, would be 110,000 acres for Alternative 6 and would range from 763,000 to 2,728,000 acres for Alternative 3, 2, and 1 in that order, respectively. Under Alternatives 4 and 7, non-development LUDs other than Old-Growth, would decrease by 333,000 and 261,000 acres, respectively. While it is recognized that not all acres within these LUDs are old growth, there would be a net increase in the reserve system under Alternatives 1, 2, 3, and 6 that is proportional to the increase in non-development LUD acres and a proportional decrease under Alternatives 4 and 7.

2.5.1.3. Net Changes to the Forest-wide Reserve Network

The acreage in reserves, given the above changes in the Old-Growth Habitat LUD and other non-development LUDs, is compared with the acreage in the matrix for the alternatives and compared with the 1997 version of the Forest Plan in Table D-5. This comparison shows that the 1997 version of the Plan included 78.0 percent of the Forest in reserves. As a result of land adjustments and OGR changes between 1997 and 2007, the 2007 Forest Plan (equivalent to Alternative 5) now has 78.5 percent of the Forest in reserves. Alternatives 1, 2, 3, and 6 would each result in a higher percentage yet, ranging from 79.4 percent in reserves under Alternative 6 to 95.0 percent in reserves under Alternative 1. Under Alternative 4, the percentage in reserves would be reduced to 71.8 percent, and under Alternative 7 this percentage would be reduced to 69.9 percent.

Table D-5.
Summary of Acreages in Reserves and Matrix under the Alternatives compared with the Forest Plan in 1997

Alternative	Reserves			Matrix	Total	Percent of Forest in Reserves
	Old-Growth Habitat LUD	Other Non-Dev. LUDs	Total in Non-Dev. LUDs			
Alternative 1	1,221,173	14,712,270	15,933,443	840,359	16,773,802	95.0%
Alternative 2	1,221,173	13,623,148	14,844,321	1,929,485	16,773,806	88.5%
Alternative 3	1,221,173	12,748,685	13,969,858	2,803,945	16,773,803	83.3%
Alternative 4	393,360	11,652,756	12,046,116	4,727,686	16,773,802	71.8%
Alternative 5 (1997 Forest Plan)	1,182,424	11,985,410	13,167,834	3,605,974	16,773,808	78.5%
Alternative 6	1,221,173	12,095,212	13,316,385	3,457,420	16,773,805	79.4%
Alternative 7	0	11,724,107	11,724,107	5,049,695	16,773,802	69.9%
1997 Forest Plan	1,131,059	12,034,860	13,165,919	3,717,081	16,883,000	78.0%

Sources: Final EIS Chapter 2 for the Alternative numbers; Appendix N to the 1997 Tongass FEIS and Appendices to Appendix N for 1997 numbers.

A summary of POG acres in reserves and in various matrix categories is provided in Table D-6. This table presents POG acreages for the Forest-wide reserve network under Alternatives 1, 2, 3, and 6, given the above changes in the Old-Growth Habitat LUD and other non-development LUDs, as well as under Alternatives 4, 5, and 7, which do not include the above changes in the Old-Growth Habitat LUD. The table also compares these alternatives with the 1997 version of the Forest Plan. Based on these numbers, the 1997 version of the Forest Plan included 70.1 percent of the existing POG in reserves; combined with the protected and unscheduled POG in the matrix, 90.6 percent of the current POG was protected or not scheduled to be harvested. Again, Alternatives 1, 2, 3, and 6 would each result in higher percentages for both of these categories, with 72.0 percent of the POG in reserves and 91.0 percent of the existing POG protected or not scheduled for harvest under Alternative 6.

Under Alternative 5 (the 2007 Forest Plan), 71 percent of the existing high-volume POG (SD Model types 5N, 5S, and 67) and 68 percent of the existing large-tree POG (SD Model type 67) would be included within reserves (Table D-6). Overall, 90 percent of the existing high-volume POG and 89 percent of the large-tree POG would not be harvested. These percentages would all remain the same or increase under Alternatives 1, 2, 3, or 6 because of the changes made to OGRs and other LUDs, which resulted in a greater portion of the forest types consisting of larger trees being included within reserves. Under Alternative 6, for example, 73 percent of the high-volume POG and 70 percent of the large-tree POG would be included within reserves. Overall, 90 percent of the existing high-volume POG and 89 percent of the large-tree POG would not be harvested. Alternatives 1, 2, and 3 would protect higher percentages of high-volume and large-tree POG in reserves and in the matrix. Under Alternatives 4 and 7, on the other hand, lower percentages would be protected. Approximately 57 to 60 percent of the high-volume POG and 53 to 57 percent of the large-tree POG would be in reserves under Alternatives 7 and 4, respectively. Overall, 82 to 85 percent of the high-volume POG and 80 to 84 percent of the large-tree POG would be protected from harvest.

Table D-6.
Estimated Acreage and Percentage of All Existing POG, High-Volume POG, and SD67 POG in Reserves[1] and Matrix Lands (minimum protected vs. maximum harvested) [2] by Alternative

Alt.	POG Category	Amount in Reserves[1]		Amount in Matrix[2] Minimum Protected		Amount in Matrix[2] Maximum Harvested		Total Existing POG[3]	
		Acres	Percent	Acres	Percent	Acres	Percent	Acres	Percent
1	All POG	4,615,995	93%	249,182	5%	85,972	2%	4,951,148	100%
	High-Volume POG	1,862,441	93%	104,444	5%	41,460	2%	2,008,345	100%
	SD67 POG	477,813	89%	43,253	8%	16,385	3%	537,451	100%
2	All POG	4,167,367	84%	569,270	11%	214,511	4%	4,951,149	100%

1997 Forest Plan	All POG	3,551,482	70%	1,038,492	21%	473,597	9%	5,063,571	100%
	High-Volume POG[4]	1,562,652	72%	373,857	17%	219,268	10%	2,155,788	100%
	SD67 POG[4]	--	--	--	--	--	--	--	--

[1] Reserves include all non-development LUDs (e.g., Old-Growth Habitat, Semi-Remote Recreation, Remote Recreation, Wilderness, National Monument, etc.).
[2] Matrix includes all development LUDs (Timber Production, Modified Landscape, Scenic Viewshed, and Experimental Forest). Maximum harvested assumes the maximum acreage permitted by the Allowable Sale Quantity is harvested each decade.
[3] Note that the Tongass land base has changed since 1997 due to land adjustments and harvest has occurred.
[4] High-volume POG numbers were derived from percentages given in Appendices 3 and 8 to Appendix N of the 1997 Tongass FEIS; numbers were not available for SD67 POG. There are differences in the method of calculation for high-volume POG between 1997 and 2008, so the absolute numbers should not be compared – only the percentages.

Sources: Table 3.9-12 in Biodiversity Section for the 2008 alternative numbers; Appendix N to the 1997 Tongass FEIS and Appendices to Appendix N for 1997 numbers.

2.5.2. Changes to Standards and Guidelines (fine-filter approach)

This section describes and provides background/rationale for the changes to standards and guidelines proposed under the seven alternatives. The first section provides a summary listing of the primary changes in standards and guidelines from the 1997 Forest Plan. Following this section, a series of sections provide background and rationale for the most important individual changes.

2.5.2.1. Overview of Changes to Standards and Guidelines by Alternative

Most of the standards and guidelines identified in the 1997 Forest Plan remain the same for all of the alternatives. The standards and guidelines for Alternative 5 would be exactly the same and most standards and guidelines related to the conservation strategy do not change under Alternatives 1, 2, 3, and 6. This includes key supporting standards, like the 1,000-foot beach buffer and riparian buffers that were deemed critically important for wildlife connectivity; these are brought forward into the amended Plan under these alternatives. However, there are four primary changes, four additional important but non-substantive changes, and some minor editorial changes to standards and guidelines that relate to Alternatives 1, 2, 3, and 6. The four primary changes associated with these alternatives are listed in a subsection below, followed by the important non-substantive changes (minor changes are not listed).

In addition, many of the changes associated with Alternatives 1, 2, 3, and 6 and several additional important changes are associated with Alternatives 4 and 7. These changes are identified in separate subsections below.

Primary Changes Associated with Alternatives 1, 2, 3, and 6

1. Added a new Forest-wide Legacy Forest Structure (hereafter referred to as Legacy) standard and guideline that requires retention of 30 percent of the acreage in harvest units greater than 20 acres in size for VCUs with high amounts of past and/or anticipated future timber harvest. This replaced the goshawk foraging standard and guideline and the marten standard and guideline that required varying degrees of retention of old growth trees in harvest units.
2. Changed the goshawk nesting habitat standard and guideline for confirmed and probable nests to allow timber harvest or other activities if, based on annual monitoring, the nest site is found to be inactive for 2 consecutive years. (note – active nest sites include sites that are occupied, whether or not there is actual nesting documented).
3. Added a stipulation to allow for alternative goshawk nest site management with projects under contract. If a new nest is located within an area that is under a timber sale or other contract, the activity may proceed if at least 300 acres of POG, including at least one contiguous block of 100 acres, remains within a 0.75-mile circular radius of the nest. Timing restrictions would apply to allow that year's brood to successfully fledge from the nest.
4. Clarified that the landscape connectivity standard was to provide connectivity between large and medium reserves only. Also, given the assessment of small OGRs done for the amendment (see below), no additional areas were determined to need additional assessment at the project level and this is reflected in the amended standard.

Other Important Clarifying Changes Associated with Alternatives 1, 2, 3, and 6

1. The endemic terrestrial mammal standard was changed to allow for use of existing data on endemic mammal distribution. Surveys would only be necessary where existing information is not adequate to assess project level effects.
2. Edited the marten road standard to clarify that road management would be considered only where road access and associated human caused mortality has been determined to be the significant contributing factor to unsustainable marten mortality and this would be done in collaboration with the Alaska Department of Fish and Game (ADF&G).
3. Edited the wolf road standard to clarify that road management would be considered only where road access and associated human caused mortality has been determined to be the significant contributing factor to unsustainable wolf mortality, and this would be done in collaboration with ADF&G. It also directs an assessment of both total and open road density when human access considerations are necessary. The wolf standard was changed so that both access management on National Forest System lands and hunter/trapper harvest regulations are considered.

4. Edited the wolf standard to clarify the use of the deer habitat capability model and standardized this to a habitat capability of 18 deer/square mile. The wolf standard was also changed to direct biologists to consider local knowledge of habitat conditions, spatial location of habitat and other factors rather than solely relying upon model results.

Changes Associated with Alternative 4

All of the changes associated with Alternatives 1, 2, 3, and 6 also apply to Alternative 4, except the Legacy standard and guideline. Neither the Legacy nor the goshawk foraging standard and guideline and marten standards and guidelines apply to Alternative 4. In addition, as noted in the introduction to Section 2.5, Alternative 4 has a standard that requires a minimum of 33 percent of POG be retained in VCUs outside of the four biogeographic provinces that include areas with designated Old-Growth Habitat LUDs.

Changes Associated with Alternative 7

All of the changes associated with Alternatives 1, 2, 3, and 6 also apply to Alternative 7, except for the Legacy standard and guideline and the goshawk nest buffer standard and guideline. Neither the Legacy nor the goshawk foraging and marten standards and guidelines apply to Alternative 7 and there would be no nest buffer standard and guideline that is specific to goshawks; only the general heron and raptor nest protection standard and guideline would apply. In addition, riparian buffers along Class III streams are not required under Alternative 7 and the beach and estuary fringe is reduced to 500 feet.

2.5.2.2. Legacy Standard and Guideline – Alternatives 1, 2, 3, & 6

Background from 1997 Tongass Land and Resource Management Plan

The Legacy Forest-wide standard and guideline is an ecological, rather than single-species approach, that retains old-growth forest structure within harvest openings greater than 20 acres in areas that have had or are anticipated to have high timber harvest. The legacy standard and guideline evolved from considerations presented at the Interagency Conservation Strategy Review workshop (summarized in USDA Forest Service 2007). This standard and guideline was developed after discussions with ADFG and FWS at several interagency meetings in 1997. It replaces the species-specific goshawk foraging and marten standards and guidelines from the 1997 Forest Plan Revision to provide protection for goshawk, marten and other wildlife species across a broader landscape. Goshawk foraging and marten standards and guidelines, that prescribed retaining canopy cover in high risk biogeographic provinces, were conservation measures added to the Forest Plan in the Record of Decision to provide additional protections and to increase the already high likelihood that implementing the Forest Plan would maintain habitat to provide for viable populations of goshawks and moderate likelihood that implementing the Forest Plan would maintain habitat to provide for viable populations of marten. This subsection provides a summary of the background for the new Legacy standard and guideline by describing the history of the goshawk foraging and marten standards and guidelines.

American Marten

The risk assessment panel convened in 1997 indicated that there was a better than equal likelihood that implementation of Alternative 11 for 100 years would result in significant gaps in marten habitat distribution on the Tongass (DeGayner 1997). Alternative 11, with modifications, was the Alternative selected in the Record of Decision for the 1997 FEIS. Their interpretation of the outcomes that were used as the basis for risk assessment is as follows (a complete description of the panel assessments with the 5 outcomes is described later in this document in the Wildlife Viability Ratings section). Outcome III, defined as providing habitat to maintain breeding populations but with significant gaps in historic distribution, was interpreted by the panelists as an array of potential conditions. At one end of this array were gaps in habitat as small as the territory of a single marten. At the other end this array was conditions with broad gaps in habitat distribution and significant limitations on population interactions. The panelists considered some part of this array of conditions as meeting the definition of viable and well-distributed. The panelists assigned a total of 91 likelihood outcome points to the sum of Outcomes 1 + II + III. This included 38 likelihood points in Outcomes I and II, which they considered to represent a viable and well distributed condition. It also includes 55 likelihood points in Outcome III, some portion of which represents a viable and well distributed condition. The panelists indicated there was a very low likelihood that marten would exist only in refugia or be extirpated from the Tongass after 100 years of Forest Plan implementation with a combined Outcome IV and V score of 9. The panelists indicated that matrix management was the feature of the 1997 Alternative 11, as rated, that contributed to the assignment of likelihood points to outcomes that were not well-distributed. They indicated that clearcut silviculture on a 100-year rotation would result in further fragmentation of marten habitat.

The panel evaluators defined the spatial scale of a gap to be one vacant marten territory. A marten territory was considered to be from one to three square miles. The consequence of a gap is some measure of reduced gene flow within the population. Panel evaluators indicated that a population can accommodate a certain, but unknown, level of gaps and still remain viable. The greater the size and number of gaps, however, the higher the risk of reducing gene flow. To avoid creation of gaps by forest management practices, panel evaluators recommended uneven aged harvest, in contrast to clear cutting in blocks, be coupled with a reduced level of timber harvest in the matrix lands. The panel recognized the high degree of natural fragmentation on the Tongass National Forest. The panel could not, however, identify the threshold of POG remaining at which a landscape or a territory would not be suitable for marten reproduction (DeGayner 1997).

The panel was very conservative in their assessment of the definition of a gap, which lead to the assignment of most points in Outcome III. The overall assessment of a moderate likelihood of maintaining viable marten hinged on the 55 likelihood points in Outcome III and the fact that some undetermined portion of this outcome likelihood represented a viable and well distributed condition. It is also important to note that the panel assessed the 1997 Alternative 11 without the additional conservation measures that were added at the decision stage. Even without these additional measures, the panel projected no likelihood that marten would be extirpated from the entire forest under this alternative. Forest Plan was strengthened at the decision stage subsequent to the panel assessment, primarily due to the level of concern about the likelihood of marten populations remaining well-distributed across the Tongass for at least 100 years.

The measures used to strengthen the alternative were based on comments provided by the panelists, information drawn from past studies on marten, and information on existing habitat conditions on the Tongass. Three different measures were applied to Alternative 11 to improve the likelihood of maintaining habitat to support well-distributed populations of marten.

1. Within the five higher risk biogeographic provinces, stands would be managed under practices other than clearcutting.
2. Access management would be used to reduce marten mortality in areas where mortality rates due to trapping/hunting have been identified as a serious risk to marten populations.
3. Additional assurance of maintaining connections between habitat blocks throughout the Tongass would be considered.

Implementation of the above strategy increased the likelihood of maintaining habitat that supports well-distributed marten populations. While it was anticipated that there would likely be gaps in this distribution, there was a low likelihood that there would be significant isolation among marten populations resulting from implementation of the 1997 Forest Plan.

Goshawk

Alternative 11 of the 1997 Forest Plan was rated as having very low likelihood of goshawks existing in refugia or being extirpated from the Tongass after 100 years of Forest Plan implementation. However, because the goshawk was considered for listing under the Endangered Species Act, Alternative 11 was reviewed at the decision stage to determine if features of the alternative could be modified to improve the projected outcome. An additional measure for goshawk habitat was prescribed for Prince of Wales Island where POG was fragmented by past management actions. In VCUs, where over 33 percent of POG has been converted to young stands by past management, any additional management of POG was restricted to 2-acre clearcuts or managed to leave significant structure in harvested stands. Taken in combination with other measures already in place in the Forest Plan, these additional measures increased the already high likelihood of providing habitat sufficient to maintain viable and well-distributed goshawk populations.

New information Since 1997

Scientific Literature: A considerable number of new studies on goshawks and marten relevant to the Tongass situation have been conducted since 1997. Many new studies and concerns related to the conservation of marten and goshawk were presented at the Interagency Conservation Strategy Review: An Assessment of New Information Since 1997 in April 2006 (USDA Forest Service 2007). This information is summarized along with other studies in Section 2.4.2.

Implementation of Goshawk Foraging and Marten Standards and Guidelines and Forest Plan since 1997: The 1997 goshawk foraging and marten standards and guidelines, coupled with the associated Tongass Plan Implementation Team (TPIT) Clarifications, are lengthy and complex. This complexity has lead to inconsistent interpretation and application across the Tongass (Conservation Strategy Review 2007). In addition, translating canopy cover to standard silviculture terminology has been problematic. The TPIT worked collaboratively to attempt to clarify these standards and guidelines in 1998 and allowed flexibility in the implementation of these standards. Unfortunately, this clarification was lengthier than the original standard and guideline and did not necessarily result in increased clarity. One result of the TPIT clarification was to allow flexibility to clump leave trees when operability concerns or ecological reasons made uniform placement difficult or impossible.

There have also been issues during the implementation of goshawk foraging and marten standards and guidelines. Recent compiled information indicates the lack of consistency in their Forest-wide application, despite the TPIT clarifications. A survey of Tongass District wildlife biologists done in 2007 indicates a high degree of inconsistency and uncertainty in the application of goshawk foraging and marten standard and guidelines (Fadden 2007a). Biologists were not consistent in their interpretation of the standards and guidelines and believed that there was not consistent interpretation Forest-wide. In addition, it was not necessarily clear to biologists how these standards and guidelines actually benefited marten and goshawk.

Review of a sample of planned timber sales since 1997 also demonstrates the inconsistency in application on the ground, with the goshawk foraging and marten standards being implemented using a simple percentage of the stand on some timber sales, using basal area on others, and using trees per acre on others (Fadden 2007b). All of the measures resulted in different effects on the ground, ranging from a clumped leave patches to partial harvest scattered across the unit. Within most timber sales reviewed, implementation of both marten and goshawk standards did take into account other leave areas (stream buffers, karst, etc.), which counted towards the final target (Fadden 2007b). Recommendations in this report included the need to simplify these standards to provide for more consistent application.

Monitoring of timber harvest implemented since 1997 indicates that, overall, timber harvest is occurring at a scale much less than was anticipated in the 1997 Forest Plan EIS. Annual timber harvest has been much less than the Forest Plan Allowable Sale Quantity (ASQ) of 267 mmbf. In 2004, actual harvest was 17 percent of the ASQ and in 2005, harvest was 24 percent of the ASQ. In addition, there is trend toward a decrease in size of traditional clearcuts and a decrease in opening size. Since 1997, the average clearcut harvest size is 11 acres (Conservation Strategy Review 2007). As a consequence, the effects on wildlife have been considerably lower than the level predicted by the 1997 Forest Plan FEIS.

The trend toward smaller opening sizes coupled with the increased use of partial harvest are factors that make timber sales less economical, as well as more difficult to log. A combination of factors including market issues and increased fuel and logging costs are also factors in timber sale economics; however, when coupled with less volume per acre and higher logging costs due to partial harvest, it has exacerbated the economic issues, particularly at the scale of an individual timber sale (as presented at the Interagency Conservation Strategy Review: An Assessment of New Information Since 1997 in April 2006; USDA Forest Service 2007).

The 1997 Forest Plan sought to provide for economic considerations while implementing conservation measures for species of concern. Monitoring of timber sale economics indicates that this approach, which has resulted in significantly smaller timber harvest unit size and more partial harvest, is likely contributing to significant difficulties in implementing economic timber sales. More information regarding timber sale economics can be found in the *Economic and Social* section of the Final EIS.

While this information indicates the challenge in providing for economic timber sales, the trends discussed above represent several positive consequences for wildlife. The main positive consequence is that more habitat for old-growth associated species is retained as old growth. The second consequence is the ameliorating effects of forest succession. Negative effects to goshawk and marten are strongly associated with the effects of past large-scale timber harvest on the Tongass. Past harvest resulted in much larger openings than are allowed under the 1997 Forest Plan, often occurring within riparian areas and beach buffers, which are high value wildlife habitats. Neither riparian areas nor beach buffers are harvested under the 1997 Forest Plan, nor would they be harvested under 2008 FEIS Alternatives 1, 2, 3, or 6. As young forests mature, they gradually become more suitable for goshawks and marten. Previously, little emphasis was given to the young second-growth component of the matrix in terms of its ability to contribute structure, function, or value to wildlife. However, there appears to be a growing perception that, with active management, young stands can contribute at least some of the values commonly associated with old-growth (Barbour et al. 2005). Key features of old-growth forest include large, old decadent trees, multiple canopy layers, standing snags, down woody debris, and a diverse and abundant herb layer. These features can be maintained or created by retaining structures and organisms at the time of regeneration harvest of old-growth forest and through active management of young, even-aged stands. Some potential approaches to even-aged management involve thinning of older, “commercial”-aged young-growth stands (Deal 2001, Deal and Tappeiner 2002, Deal et al. 2002), including red alder (*Alnus rubra*) in the reforestation of harvested areas to expedite the production of large-diameter conifers (Deal 1997, Deal et al. 2004, Hanley et al. 2006), and the initial use of alternatives to clearcutting (McClellan et al. 2000). It should be emphasized that additional research on the implementation of these techniques is needed.

For example, both pre-commercial and commercial thinning of young-growth stands have beneficial impacts to black-tailed deer by opening up the forest and promoting the growth of understory vegetation. Likewise, active young-growth management has the potential to benefit both marten and goshawk through an increase in small mammal populations (red squirrels and red-backed voles, major prey items of these species, benefit from more open forests with abundant understory vegetation) and by speeding the succession of older young-growth stands toward old-growth condition (Hanley 1996, 2005). Thinning also may benefit forest-dwelling birds, some of which are prey for goshawk (Dellasala et al. 1996). Although the time frame in which young-growth stands become suitable habitat for some old growth associated species is beyond the lifespan of the 10-15 years of this Forest Plan, it is something to be considered as part of a long-term vision for management of the Tongass. It must be noted however that their research on the effectiveness of young-growth management is on going and peer-reviewed results are not yet available. The evidence in support of the potential short and long term benefits of young-growth management for multiple values is derived from a series of demonstration projects that have tested various second-growth management methods (e.g., Zaborske et al. 2002; Deal et al. 2004; McClellan 2004, 2005; McClellan et al. 2005; Wipfli et al. 2003), retrospective assessments (Hanley and Barnard 1998), and other observations. Thus, there remains uncertainty about the true benefits of second-growth management to wildlife. Although active management will likely improve habitat conditions in young conifer stands, significant questions remain regarding the types of treatments, treatment timing, and cost/benefit tradeoffs.

This does not imply that young growth is the same quality habitat as old growth, nor does it ignore the negative consequences of the stem-exclusion phase, which is characterized by dense young trees that shade out most of the understory and thus, provide low habitat value for most wildlife species. But once stands transition out of this stage, they gradually begin to provide the components of good quality wildlife habitat, including larger trees, small canopy gaps, a diverse understory, snags and downed logs. Stands typically do not begin to take on the characteristics of old growth until they reach at least 150 years of age (Alaback 1982). However there is some evidence that some species associated with older forests may in fact use much younger stands (for example, goshawks - see Section 2.4.2.1).

Besides the benefits of succession, another benefit of aging young-growth stands is the increased potential value of these stands for commercial forest products and their ability to replace old growth trees for a significant portion of the supply of timber in Southeast Alaska in the future. Managing young-growth forests in Southeast Alaska is likely to become an increasingly important component of forest management on the Tongass in the coming years. Young-growth stands can be treated through thinning and other intermediate treatments to concentrate growth in fewer, larger trees, improve lumber quality, and/or to enhance habitat conditions for wildlife. Treatments applied to young stands may have a profound effect on the types of materials available in the future, including log diameter, knot size, and wood strength (see *Timber* section of Final EIS for more discussion).

Overall the consequence of substantially less harvest of old growth in the past decade coupled with the increased growth and potential value of young growth for wildlife is beneficial and supports that assumptions made regarding risks to species viability made in the 1997 Plan were conservative. This conclusion is supported by observations that some old growth associated species use younger forests that anticipated in the 1997 Forest Plan (for example, goshawks), that a shift to more commercial forest products coming from young growth forests is occurring and is likely to accelerate over the next two to three decades, and that the beneficial effects to wildlife by less harvest of old growth over the past decade than is greater than was anticipated under the 1997 Forest Plan. This is particularly significant in places with the oldest young growth, which includes some portions of Prince of Wales Island. Of the 187,000 acres of past harvest on Prince of Wales Island, 8,000 acres are now age 50 or older, 42,000 acres are now age 40 to 49, and 54,000 acres are now age 30 to 39. Within 20-30 years, much of the young growth on Prince of Wales Island may be approaching suitable nest habitat for goshawks.

<u>Annual Monitoring and ADFG Reports:</u> According to the 2006 Tongass National Forest Annual Monitoring and Evaluation Report, habitat capability for marten was expected to decrease slightly because of timber harvest activities and road construction across the Tongass. However since timber harvest levels have been substantially less than anticipated, this report documents that effects anticipated to marten under the Forest Plan have been less than anticipated. The most recent ADF&G Furbearer Report (Alaska Department of Fish and Game 2004) suggests that marten populations are stable or increasing across most of the Tongass; the exception potentially being near Juneau. In 2003, over 2700 marten were trapped in Southeast Alaska and both trappers and agency personal reported stable or increasing marten populations in most Game Management Units (GMUs). The two areas with the highest harvest levels are GMUs 2 and 4, which include Prince of Wales Island and Chichigof Island, areas with some of the highest past timber harvest on the Tongass. The link, if any, between habitat changes on the Tongass National Forest and changes in the marten population is difficult to determine. Fluctuations in prey abundance or spatially different trapping pressure are confounding factors. Areas on the Tongass with the most timber harvest continue to have stable or increasing marten populations and trapping regulations have not changed significantly on the Tongass.

<u>Queen Charlotte Goshawk Status Review and Findings</u>: The U.S. Fish and Wildlife Service was petitioned to list the Queen Charlotte goshawk as endangered in May 1994. In June 1995, the Service published a 12-month finding that listing was not warranted. The finding was challenged in U.S. District Court, which remanded the finding to the FWS with instructions to base the finding on the existing management plan for the Tongass National Forest, rather than one in development at the time. The FWS released a new finding (also “not warranted”) in August 1997, which was also challenged in April 1998, and which the court remanded again to the FWS in July 1999, with instructions to provide a reliable population estimate for the subspecies The government appealed this decision in the U. S. Court of Appeals, which overturned the requirement for a population estimate, but remanded the case to the District Court for further consideration of the remainder of the finding. In May 2004, the District Court remanded the finding to the FWS with instructions to evaluate whether Vancouver Island in British Columbia is a “significant portion” of the subspecies’ range and, if so, to determine whether the bird should be listed (U. S Fish and Wildlife Service 2007)

In order to reach an informed decision with respect to the court’s remaining questions on the significance of Vancouver Island and whether the subspecies should be listed, the FWS recently updated the status of the subspecies range-wide. In addition, the FWS published a new finding in November 2007 regarding the status of the Queen Charlotte goshawk. In this report, they concluded that Vancouver Island is a significant portion of the Queen Charlotte goshawk's range and that listing the subspecies on Vancouver Island is warranted. In addition to addressing the court's remand, they assessed whether listing was warranted for the Queen Charlotte goshawk beyond Vancouver Island. Their review indicated that the subspecies' populations in British Columbia and Alaska each constitute distinct population segments (DPSs) of the Queen Charlotte goshawk. Based on differences in forest management, with substantially greater habitat loss in British Columbia, they found that they had sufficient information about biological vulnerability and threats to the goshawk to determine that the entire British Columbia DPS warrants listing as threatened or endangered. They also found that the best available information on biological vulnerability and threats to the goshawk does not support listing the Alaska DPS as threatened or endangered at this time. Of note are the following key items from the FWS review:

- The majority of POG that existed in Southeast Alaska prior to large-scale logging would remain over time. Most (77 percent) of this habitat is on the Tongass.
- There is no data to indicate how much goshawk populations have declined as a result of timber harvest. Based on one approach, the FWS believes that populations may have declined by 15 percent in Southeast Alaska and as much as 45 percent in British Columbia.
- The most important factor related to goshawk demographics is adult survival. Adult survival is a function of prey abundance and availability.
- Southeast Alaska is relatively prey-poor for goshawks, especially on the islands of the south Tongass. For example, Prince of Wales Island lacks red squirrels and sooty grouse, which are important prey for goshawks on the mainland and islands in the north Tongass. Many studies from across the range of the goshawk suggest that prey availability is one of the most important factors regulating goshawk population size in Southeast Alaska.
- Studies from across the range of the goshawk suggest they select nest stands that have a higher proportion of mature and old forests than random sites.
- Goshawks use a wide range of habitats for foraging within the matrix, including non-forest, young forest, low-volume forests, and clearcuts.
- Goshawks, even juveniles, can travel relatively long distances across salt water, indicating that there are not likely to be barriers to goshawk movement among the islands in Southeast Alaska.

Importance of Retention of Forest Structure After timber harvest and Spatial Considerations

While the benefits of leaving old growth structure after timber harvest are well documented in the scientific literature, the need to leave it after timber harvest on the Tongass is not as clear, given the conservation strategy, the fact that slightly over 90 percent of the existing POG is protected under the 2007 Forest Plan and that there are economic consequences of leaving structure post timber harvest (see Section 2.3). However, past timber harvest has been concentrated in certain portions of the Tongass. While it is true that Forest-wide, the vast majority of old growth would be retained, there are biogeographic provinces and watersheds that have and are predicted to have much higher reductions in old growth than the average. For example, as reported in the 2008 FEIS, the North Central Prince of Wales biogeographic province currently has 74 percent of the original POG and it is anticipated that this would be reduced to 63 percent of the original POG after 100 years of timber harvest at maximum levels allowed by the Forest Plan under Alternative 6. Considering only large tree POG, North Central Prince of Wales province would retain 57 percent of original large-tree POG; however, the East Baranof province would retain only 31 percent. In these and similar areas, there would be elevated risk that there could be gaps in distribution of some species and reduction in connectivity between old-growth patches after 100 years of timber harvest at maximum levels allowed by the Forest Plan.

Many studies validate the importance of retention of legacy trees and patches of old growth after timber harvest for many forest associated species (Masurek and Zielinski 2004, Carey 2000). Retention of this old growth structure affects forest developmental pathways, indirectly affecting wildlife abundance by retaining necessary structural features in both mature and young forests (Deal 2007). In Southeast Alaska, many bird species utilize legacy trees as nesting, foraging, perching, and roosting sites (Sidle and

Suring 1986). The lack of these structural features within forests can negatively impact many old growth associated species (Bunnell *et al.* 1999, 2002, Aubry *et al.* 1999, Bevis *et al.* 2002, Deal 2001, 2007). Work on flying squirrels in Southeast Alaska indicates the importance of the matrix in providing adequate dispersal habitat in order to maintain connectivity between OGRs. Flying squirrels, being arboreal, require these structural components and are found primarily in mature and old growth forests but are also found at lower densities in peatland –scrub forests (Smith and Person 2007).

While numerous studies validate the importance of retention of this structure, research is not available, especially for Southeast Alaska, to guide specific silvicultural prescriptions or to help prescribe specific amounts of leave trees for individual wildlife species. Most Forest Plans in other parts of the United States have incorporated various retention prescriptions. The closest plan ecologically to Southeast Alaska is the Northwest Forest Plan that covers Oregon and Washington. The Northwest Forest Plan requires green-tree retention in at least 15 percent of the area within logging units. It is recommended that at least 70 percent of this retention be implemented in patches or clumps of up to one hectare (about 2.5 acres). In addition to this green-tree retention, the retention of snags and large decadent trees within these green-tree retention clumps is recommended. These prescriptions were developed based on the professional judgment and collective biological knowledge of individuals who have studied the ecological processes characterizing the forests of the Pacific Northwest (Aubry et al. 1999). A large-scale and long-term experiment (the Demonstration of Ecosystem Management Options (DEMO) study) to evaluate the ecological effects and public perception of green-tree retention in western Washington and Oregon is underway. Among the key findings to date are that the pattern of retention is not as important as the amount of retention; however, the retention of 2.5-acre clumps can provide refuges with ecological and mircroclimatic conditions that enable many sensitive species to persist, at least in the short term (USDA Forest Service 2007).

In Southeast Alaska, research has described the characteristics of wind-created openings (Nowacki and Kramer 1998). Understanding the range of natural wind disturbance gaps can help in the development of management prescriptions. Within the four areas studied by Nowacki and Kramer (1998), mean gap size sustaining large-scale wind events ranged from 10 to 39 acres in four study areas, with the range in size of individual gaps from 1 to 1,000 acres. Within gaps, there was also a range in the amount of remnant trees remaining after a windthrow event, with some remnant structure in most gaps. Most gaps had a range from 0 to 50 percent of the stand remaining post wind event.

The 1997 Forest Plan used a harvest unit threshold of 2 acres, for the implementation of goshawk foraging and marten standards and guidelines. No documentation of why this acre threshold was used can be found in the 1997 FEIS; however, there is reference to the practice of group selection in the timber section of the 1997 FEIS. The group selection method prescribes the removal of small groups of trees to create openings in the stand. The forest created, using this method, is a mosaic of small groups of trees of uniform age and height with the goal of regenerating an uneven-aged stand structure across the landscape. Group sizes range from 0.1 acre to approximately 2 acres in size. Research and experience with this method is extremely limited in Southeast Alaska. The ideas behind using this method in Southeast Alaska are to protect excessively steep or unstable soils and reduce the impacts to scenic and wildlife resources.

Rationale for Legacy Standard and Guideline

The legacy standard and guideline as a replacement for the species-specific goshawk foraging and marten standard and guidelines is proposed for the following reasons:

1. It provides a science-based measure of retention of old-growth habitat characteristics (large trees, down logs, snags) Forest-wide rather than only in places where there were concerns related to goshawk and marten. This will provide habitat protections in high risk biogeographic provinces across the forest for more species of concern (including endemic small mammals and forest birds) than the goshawk and marten standards and guidelines in the 2007 Forest Plan.
2. It provides an alternate method for retaining connectivity and prey base for marten and goshawk at the watershed scale. Legacy would apply in 49 VCUs Forest-wide in 7 biogeographic provinces. Goshawk foraging standards under the 2007 Forest Plan apply in 22 VCUs on Prince

of Wales Island only (1 province). Marten standards for high risk provinces under the 2007 Forest Plan apply in 12 VCUs in 2 provinces. Marten standards for moderate risk provinces in the 2007 Forest Plan apply in 107 VCUs in 6 provinces. These standards for low risk provinces apply in 112 VCUs in 6 provinces.

3. Overall, considered in combination with other improvements to the Conservation Strategy, including increased quality of small OGRs, increased old-growth protection in key areas, and increased quantity (acreage) of OGRs, habitat for viable populations of goshawk and marten across the Tongass would be maintained.
4. The Legacy standard and guideline is simpler to implement and will likely have more consistent implementation Forest wide than the previous goshawk foraging and marten standards and guidelines.

These four reasons are explained in detail below.

1. Providing a science-based measure of retention of old-growth habitat characteristics (large trees, down logs, snags) Forest-wide and the value to multiple species.
A review of current science, as described previously, supports both the value of the retention of old growth structure to a wide range of species and the value of taking a broader approach, rather than taking a single-species approach as did the goshawk foraging and marten standards. While the value of retaining old-growth forest components within landscapes managed for timber production has a sound basis in science, there is no scienific basis to support specific prescriptive standards for marten, goshawk or most individual species. In other words, while there may be a scientific basis that supports that partial harvest has less impact to goshawk or marten habitat than clearcutting, there is no scientific basis to support any specific management prescription. Clearly, there is a gradient of the value of habitat conditions for many species, with large contiguous blocks of old growth being most beneficial for many old growth associated species in Southeast Alaska and large expanses of clearcut forest being the least beneficial. But without specific studies indicating what specific prescriptions are of most value, the management decision for these prescriptions are made by considering the risk to the resource (in this case wildlife habitat needs) with the feasibility requirements for other management (in this case, economic timber harvest).

Furthermore, while 1997 Forest Plan prescribed retention of 10 to 30 percent canopy cover as a measure to help maintain connectivity for marten and to maintain foraging habitat for goshawk, there is no scientific basis to support that this relatively low amount of retained canopy cover in a stand provides measurable protection specific to goshawk or marten or their prey. Also there is no scientific basis to support that this degree of retention of canopy cover is effective for maintaining connectivity in fragmented landscapes. The studies summarized previously indicate that more than significantly more than 30 percent canopy cover would need to be retained to meet these objectives. While increased amounts of retention post timber harvest may benefit old growth associated species, including marten and goshawk, they present conflicts in providing for economical timber harvest.

Based on current science, leaving old growth structure post timber harvest in clumps is preferable to leaving the structure in a more uniform configuration across a clearcut because clumps of trees are more likely to be used by a variety of wildlife species, they may benefit other organisms in the forest, and they are more windfirm than scattered trees. As noted above, the DEMO study in western Washington and Oregon has found that many plant and animal species that are sensitive to timber harvest were able to persist in retention clumps of 2.5 acres, indicating that such patches may serve as local sources of recolonization into adjacent harvested areas as the new stand develops (USDA Forest Service 2007).

Leaving structure in clumps rather than scattered is also more efficient for logging with the consequence of reduced logging costs in cable-yarding harvest units. The recently completed logging system and transportation analysis (LSTA) for the Tongass indicates that only 35 percent of the remaining suitable old growth is planned for cable yarding (see Table 3.13-2 in the *Timber* section of the Final EIS). The remaining 65 percent is planned for ground-based logging systems, such as shovel logging, or helicopter. With ground-based or helicopter logging, there is substantial flexibility in terms of how retention trees could be left without significantly affecting logging costs. If only the normal operability ground is considered (excluding the difficult and isolated operability classes), the percentage of ground-based and helicopter yarding would still be 61 percent. Therefore, there is considerable flexibility available to project IDTs for the majority of future old-growth harvest units, to design retention spatial patterns in a way that is beneficial to wildlife and does not negatively affect timber sale economics.

The legacy standard and guideline addresses the high degree of endemism within the islands of the Tongass and a degree of uncertainty in managing for endemic species because of gaps in information about species distribution and habitat needs. While recent science addresses concerns regarding endemic mammals related to risks of extinction due to island factors and small population sizes and connectivity within islands, there remains a lack of a scientific basis to help managers develop species-specific conservation measures. Therefore, taking an ecological approach to leaving legacy that spans the entire Tongass and focuses on watersheds with a high degree of past timber harvest (harvest that occurred prior to the 1997 Forest Plan) is an approach that, in the absence of science to support other measures, will most likely help ensure connectivity for a wide range of species.

2. Providing an alternate method for retaining connectivity and prey base for marten and goshawk at the watershed scale.

The objectives of the 1997 Forest Plan goshawk foraging and marten standards and guidelines were to improve connectivity for marten by reducing fragmentation, improve habitat conditions to provide for dispersal for goshawks between OGRs and to maintain foraging habitat for both goshawks and marten in the matrix in biogeographic provinces with a high degree of past timber harvest. This was done through the retention of forest stand structure important to these species and their prey (large trees, snags, and down logs) through several standards and guidelines, including those specific to goshawk foraging and marten habitat.

The legacy standard and guideline would apply under Alternatives 1, 2, 3, and 6 for the 2008 Forest Plan Amendment Final EIS within seven high-risk biogeographic provinces, as compared to the 1997 goshawk foraging standard and guideline, which applied one biogeographic province on Prince of Wales Island, and the marten standards and guidelines, which applied in two high-risk biogeographic provinces and three additional moderate-risk biogeographic provinces (Table D-7).

One of the factors contributing to the high likelihood of maintaining sufficient habitat for viable populations of goshawks in the 1997 Forest Plan was the application of a 300-year ‘ecological’ rotation. While not a rotation as defined in traditional silvicultural terminology, the concept is applied at larger, landscape scale. Application of a 300-year ‘ecological’ rotation generally results in 1/3 of the productive forest landscape in 0-100 year-old stands (low value to goshawks or most of their prey), 1/3 in 100-200 year old stands (moderate value to goshawks and their prey), and 1/3 in 200-300 or older (old growth) stands (highest value to goshawks and their prey). These proportions of habitat within the scale of goshawk use areas (i.e., median home range of approximately 10,000 acres) across a large landscape would provide habitats with a high likelihood of sustaining well distributed populations. Both extended traditional rotations and the concept of a 300-year ‘ecological’ rotation were viewed favorably by members of the Goshawk Assessment Panel for sustaining long-term goshawk habitat (Iverson, 1996). Panel members, as did authors of the Goshawk Assessment, concluded that maintaining conifer stands in intermediate age stand structure from 100 to 200 years would, in part, supply stand structure for goshawk prey production, and thus, goshawk foraging opportunities.

Alternatives 1, 2, 3, and 6 for the 2008 Forest Plan Amendment FEIS include the Legacy standard, which requires 30 percent of a stand to be retained in higher risk VCUs for even-aged harvest units over 20 acres in size. Most (over 80 percent) of VCUs within the suitable land base are categorized as low or medium risk because these VCUs currently have more than 67 percent of their historical old growth remaining and will not have more than 67 percent harvested after 100 years of harvesting at the maximum ASQ level.. Because these VCUs will continue to be managed on at least an ecological 300-year rotation, these VCUs have a high probability of maintaining adequate wildlife habitat for many species, including marten and goshawk.

This approach addresses the potential cumulative effects from previous harvest and provides for the retention of a representation of old-growth components across all VCUs managed for timber production. In low and moderate risk VCUs, the representation of old-growth components is provided for by the mix of non-development LUDs, OGRs, and other standards and guidelines. In high risk VCUs, this is provided for by the legacy standard plus the mix of non-development LUDs, OGRs and other standards and guidelines.

Implementing the legacy standard and guideline in high risk VCUs will help ensure connectivity between OGRs within the matrix where connectivity may have been affected by past harvest practices. There is a high likelihood that VCUs with little past harvest will have a high degree of connectivity even after 100 years of implementing the Forest Plan because of the suite of protective measures that are in place under Alternatives 1, 2, 3, 5, and 6.

Table D-7 provides a summary of the number of VCUs where the legacy, goshawk, and marten standard and guidelines apply. There are two scenarios within which the legacy standard and guideline differs from the goshawk foraging and the marten standards and guidelines. First, there is no requirement to leave 30 percent legacy in harvest units 20 acres or smaller in size. Legacy would only be left in harvest units that are greater than 20 acres and this number was selected because it represents a typical harvest unit, based on analysis of the Logging System Transportation Analysis (LSTA). This typical harvest unit

[1/] Marten standards and guidelines include one level of retention in VCUs with >33 percent harvest and one level for VCUs with <33 percent harvest. The VCUs listed in the first column under marten will always follow the >33 percent harvest retention rules and the VCUs in the third column under marten will always follow the <33 percent harvest retention rules. The VCUs in the middle column start out under the <33 percent harvest retention rules and switch after the 33 percent harvest threshold is reached.
[2/] The VCUs listed in this column under marten are additional to VCUs that are counted under the Goshawk standard and guideline.

is what is available for harvest after considering landforms, land suitability, Tongass Timber Reform Act riparian buffers and other resource considerations mapped for the LSTA. For wildlife species sensitive to forest fragmentation, smaller clearcuts are better than larger clearcuts. Legacy was retained only in units greater than 20 acres in response to the challenge of providing economic timber sales while conserving wildlife habitat. This was chosen because of the lack a clear scientific basis for determining what sized clearcuts are absolute barriers to wildlife, because there is no clear scientific basis to support that 10 to 30 percent canopy cover retention mitigates the effects of clearcutting on wildlife and in order to address timber harvest logistical and economic considerations.

Because legacy only applies in openings greater than 20 acres in size, there is a risk of increased negative consequences for goshawks and marten at the stand scale than was anticipated in the 1997 Record of Decision (but not in the 1997 FEIS, see discussion in 3 below). However, considering that wildlife encounter both natural and human caused fragmentation on the Tongass, opening sizes from natural wind events range up to 1,000 acres, but are typically less than 40 acres, and there are few actual barriers (except saltwater) for many species on the Tongass, wildlife movements will continue to be facilitated through managed landscapes. While there would be openings as large as 20 acres without retention of legacy, a typical timber sale layout will have a mix of unit sizes and configurations. The combination of all the protective measures specific in the Forest Plan, including riparian buffers and implementation of other standards and guidelines, will result in timber sale layout that has significant more leave as compared to pre 1997 Forest Plan timber harvest practices.

The second scenario where legacy differs is that marten standards require two additional measures of retention that are not prescribed with the legacy standard and guideline. First, marten standards under the 2007 Forest Plan require 30 percent canopy cover retention in VCUs that would, in the future, have > 33 percent of the VCU harvested in what are considered high risk biogeographic provinces for marten. Alternatives that adopt the legacy standard and guideline would not require this additional measure; however, these VCUs are considered to be moderate risk overall, because a higher percentage of their harvest will have occurred under more protective standards and guidelines and a higher percentage of retention will be present, compared with VCUs that are rated as high risk by the legacy standard and guideline. Second, marten standards require a smaller level of retention (10-20 percent) in VCUs that would never exceed 33 percent harvest. Again, alternatives that adopt the legacy standard and guideline would not require this additional measure; these are considered to be low risk VCUs, which will have an even higher percentage of retention within the matrix due to the fact that the harvest percentage is low and/or a greater percentage of the harvest will have occurred under more protective standards and guidelines (which require more retention).

Observations from implementing the Forest Plan since 1997 indicates that there are multiple standards and guidelines that provide residual forest structure (trees, snags, down logs) that are retained within timber harvest units. Besides marten and goshawk standards, these include scenery, riparian buffers (including class III streams), soils, and karst standards. In addition, logging system limitations (such as blind leads) also result in portions of stands being retained that are often unreachable with cable logging systems. Partial harvest has also occurred more frequently than anticipated, due to a variety of factors, not just marten and goshawk standards and guidelines. These observations indicate that there is significant structure being retained within watersheds as a result of the Forest Plan standards and guidelines and this structure will provide habitat for many wildlife species, including marten and goshawk.

3. Overall, considered in combination with other improvements to the Conservation Strategy, including increased quality of small OGRs, increased old-growth protection in key areas, and increased quantity (acreage) of OGRs, habitat for viable populations of goshawk and marten across the Tongass would be maintained.

Under the 1997 Plan, the viability assessment for marten (with the assumption of the maximum timber harvest levels allowed over 100 years) of the selected Alternative indicated a moderate likelihood of maintaining viable and well distributed populations of marten across the Tongass. The viability assessment for goshawk indicated a high likelihood of maintaining viable and well distributed populations of goshawks across the Tongass. These determinations were made prior to additional conservation measures added in the Decision. The 1997 Forest Plan and the 2008 Forest Plan EIS both assume that matrix lands would be somewhat fragmented by timber harvest and recognized the risks to wildlife within a fragmented landscape. It was assumed that a consequence of implementation of timber harvest at maximum levels allowed in the Forest Plan over 100 years was that there would be a reduction in wildlife habitat capability in those watersheds that had significant amounts of fragmentation due to timber harvest, hence the importance of the reserve system. Research focused on the conservation strategy since 1997 has confirmed an assumption of the 1997 Forest Plan that for some species, the OGR system alone may not retain viable populations. This was why the Forest Plan approach of both a reserve system and matrix management was adopted in 1997. Under Alternative 6, total reserve area (non-development LUDs) has been increased by over 150,000 acres and protections are even greater under Alternatives 1, 2 and 3, when considering all additions to non-developments LUDs including small OGRs, increases to geologic special interest areas for karst and increases for other resources. A substantial portion of these additions is POG.

The potential effects to marten described for Alternative 6 in the Final EIS for the 2008 Tongass Forest Plan Amendment are within the range of effects predicted in 1997. These effects would be less under Alternatives 1, 2, and 3. The 1997 Tongass Forest Plan EIS estimated there would be a moderate likelihood that marten populations would remain viable with the selected Alternative throughout the Tongass, before the marten standard and guideline was added in the 1997 ROD to further reduce risk. Alternatives 1, 2, 3, and 6 also reduce risks to marten viability through increased protective measures for marten above and beyond what the viability panels assessed. These additional measures include increased old growth acres retained in both OGRs and other non-developments LUDs; retention of the marten road density and landscape connectivity standards and guidelines; and the addition of the legacy standard and guideline.

Furthermore, the level of risk to goshawk and marten viability described in the 1997 FEIS would be realized only under a certain set of conditions, as follows.

- Timber is harvested continually at the maximum level allowed under the Plan (the ASQ level annually) for 100 consecutive years, with no change in applicable standards and guidelines during that entire period. In essence, the panels did not assess the risks associated with a 10- to 15-year decision, but with a 100-year decision. This risk is relatively low because timber has not been harvested on the Tongass at or near the maximum ASQ level throughout a single planning cycle, let alone several. The first Tongass Forest Plan was adopted in 1979, and was in effect through May of 1997. It had an annual average ASQ of 549 MMBF of total volume. Total volume harvested from 1980 through 1996 averaged 327 MMBF annually, only 60 percent of the ASQ. Since adoption of the 1997 Forest Plan, total volume harvested has averaged 84 MMBF annually, only 32 percent of the annual average ASQ of 267 MMBF.
- If timber harvest rises to the ASQ annually over the next 10-15 years the planning process ensures that any issues that may emerge regarding sustaining viable populations of wildlife species on the Tongass will be addressed. Plans must be revisited through a public process every 10-15 years. Each time, the latest scientific information is examined to determine what changes may be needed. The Forest Service and other State and Federal agencies will continue to monitor implementation of the Forest Plan and its results. If a viability-related problem were to develop, it would be addressed.
- Standards currently in effect are far more protective than those of 20 or 40 years ago. It is highly likely that standards will continue to become more effective over the next several decades through adaptive management as the scientific understanding of how to minimize the adverse environmental effects of human activities continues to improve.

In addition, consideration of the increasing value of aging young-growth stands is crucial when assessing habitat values in the matrix. As young growth matures, habitat becomes more suitable for a variety of forest-dwelling prey. The matrix also increases in value for foraging goshawks, for providing nest sites for goshawks and to provide a variety of habitat conditions beneficial to marten. In addition, not all existing young growth will be managed in the future on an 80 to 100 year rotation. Of the approximately 440,000 acres of harvested lands on the Tongass, 45 percent is within non-developments LUDs and will be managed to enhance future old-growth habitat.

Overall, implementing the legacy standard and guideline increases the likelihood that the matrix will provide many more functions than just connectivity and will help ensure the persistence of all species on the Tongass. While adoption of this standard and guideline a degree of increased risk with respect of the conservation of goshawk and marten specifically because the legacy standard applies in less VCUs that the 1997 marten standards and guidelines applied and because it applies only in openings greater than 20 acres, this risk does not change the overall conclusion that there is a moderate to high degree of likelihood that sufficient habitat will be maintained to provide for viable populations of marten and goshawk.

4. The Legacy standard and guideline is simpler to implement and will likely have more consistent implementation Forest wide than the previous goshawk foraging and marten standards and guidelines.
The legacy standard and guideline is simpler and clearer than the goshawk and marten standards. The intent is similar – retain forest structure in units after timber harvest. The standard is clear that this structure is meant to be within the harvest units, not on the edge, though it does provide for exceptions when logging systems preclude this. The Forest Plan monitoring plan requires monitoring for a variety of wildlife questions. Adjustments can be made through this adaptive management process if it is determined that our objectives are not being met.

In addition, the goshawk foraging and marten standards and guidelines, with the TPIT clarifications, have often been implemented very similarly to how we expect the legacy standard and guideline to be implemented. Particularly in units harvested with cable yarding systems, patches of old growth have been left as a proportion of the unit, rather than as dispersed trees or as by retention of canopy cover. Observations indicate that canopy cover is difficult to measure and implement and, therefore, a portion of the stand has been left to meet the standards and guidelines. Therefore in high risk VCUs, implementation of the legacy standard and guideline will be the same on many Ranger Districts as was done using goshawk foraging and marten standards and guidelines.

2.5.2.3. Goshawk Nest Buffer Standard and Guideline – Alternatives 1, 2, 3, 4, & 6

Background

Under Alternatives 1, 2, 3, 4, and 6, the goshawk nest buffer standards and guidelines were modified to read as follows:

1. Preserve nesting habitat around all confirmed and probable goshawk nests. If, based on annual monitoring, a previously active nest is found to be inactive for 2 consecutive years, protection measures for the site may be removed.
2. When a new nest is located within an area that is under a timber sale or other contract, the activity may proceed if at least 300 acres of POG, including at least one contiguous block of 100 acres, will remain within a 0.75-mile circular radius of the nest. Timing restrictions on some activities will be applied to allow that year's brood to successfully fledge from the nest.

The purpose of change 1 was to allow for future tiimber harvest in areas if evidence indicates goshawks have discontinued use of the nest stand. Note that this considers active nest sites very conservatively and include sites that are occupied, whether or not there is actual nesting documented.

The purpose of change 2 was to allow a measure of flexibility when goshawk nests are found during implementation of a timber sale or other contract. This is of particular concern during timber sale contracts, but also could occur during implementation of other contracts. Goshawks predominately have alternate nests within a territory. When found, active nest sites are protected with a 100-acre nest buffer, but there is a high likelihood that the pair will move to an alternate nest site in subsequent years. Since timber sales are planned several years in advance of actual harvest, the likelihood of this happening before harvest, when a timber sale is under contract, is compounded. When goshawks move to an alternate nest, it is particularly problematic for management if they move into a timber sale unit or within a road location after a contract has been awarded. In this case, unless the purchaser and Forest Service can come to a mutual contract agreement, the government becomes liable to claims when the nest is buffered and the unit or portion of unit is dropped from the contract. Therefore, it is desirable to have flexibility to address these contract issues on a case-by-case basis.

New science relevant to goshawks and the conservation strategy is summarized in Section 2.4.2.1.

Rationale

The use of alternate nest sites within a territory coupled with the year-to-year variation in actual nesting makes it difficult to determine if goshawks are actively nesting within a nest stand or territory. Research indicates that goshawks commonly have multiple alternate nests within a territory. Alternate nests may occur within the 100 acre nest buffer or could elsewhere within the territory. Within one study in Southeast Alaska, only 54 percent of alternate nests occurred within 100 acres of known nests, indicating that goshawks commonly move nests outside known nest stands (USDA Forest Service 2007). This, coupled with the difficulty in finding nests in Southeast Alaska means there is some risk that observers will fail to detect an active nest within the territory. In addition, because goshawks do not necessarily nest every year and may go several years between successful nesting attempts, there is some risk that managers will not be absolutely certain a nest site is abandoned after inventorying for only 2 years. It is labor intensive to find goshawk nests and verify actual reproduction in a territory. This is even more costly in the remote, inaccessible terrain of Southeast Alaska. Since goshawks may not attempt to nest for 2 or more years and individual goshawks are highly variable in the number of years between successful nesting attempts, the only method for managers to be absolutely assured that goshawks are no longer using a territory would be cost prohibitive. Using 2 years allows some measure of assurance that managers will not inadvertently harvest an active nest stand, but this is not without risk. There is some risk that a once active nest stand will be logged because not all nesting goshawks are detected and because some goshawks pairs may return to nest in a stand after two or more years absence. In addition, there is some risk that the nest stand may become unsuitable for future nesting.

Standards and guidelines outline relatively conservative criteria for what constitutes confirmed and probable nests. Observers do not need to actually find the nest to confirm a stand as a nest stand requiring a 100 acre buffer. A confirmed stand is one where evidence suggests nesting is highly likely and mangers can be relatively assured that they have identified the actual nest tree. Characteristics of confirmed nests include goshawks observed on or near a nest; nestlings or branchers (young not able to fly) observed on or near a nest; goshawk feathers or eggs obtained from the nest or one or more nest structures indicative of goshawk were found with goshawk prey remains, but without positive identified goshawk on the nest and without positive identified feathers from nest. A probable nest is one where evidence suggests nesting is likely nearby, but there is less assurance that managers know where the actual nest tree is. Characteristics of probable nests include aggressive, territorial breeding season adults vocalizing or attacking an observer (without locating a nest); or adults observed during the breeding season in a territory and recently fledged young were observed (without locating a nest).

The fact that timber harvest occurs at all within a goshawk nest territory presents some risk that the goshawk pair will not successfully nest and may ultimately abandon the territory. However, most goshawk nesting habitat on the Tongass will not be affected by timber harvest. Assuming goshawks occupy suitable habitat across the entire the Tongass, most goshawk territories would be protected by virtue of the fact that the majority (71 to 72 percent) of existing POG is protected in reserves (Table D-8).

Providing protection for goshawk nest stands continues to be an important component of goshawk conservation measures in the Amended Forest Plan under Alternatives 1, 2, 3, 5 and 6. Goshawk nests and nest territories are protected in a variety of ways, including the implementation of 100-acre nest buffers within timber harvest areas. Within the matrix, an additional 17 to 18 percent of the existing POG would be protected within the matrix by a suite of buffers and standards and guidelines. Finally, at least an additional 1 percent of existing POG would not be scheduled and would not be harvested primarily because of economics; however, based on the recent history of harvest levels on the Tongass, this percentage could be substantially higher. In total, over 90 percent of the existing POG would be protected over the life of the Forest Plan under Alternatives 5 and 6.

Table D-8.
Summary of POG Protection under Alternatives 5 and 6.

	Alternative	Protected in Reserves (OGRs, Wilderness, Nat. Mon., LUD II, and other Natural Setting LUDs	Protected in Matrix (beach fringe, riparian and other areas protected from harvest by standards and guidelines)	Minimum POG Not Scheduled for Harvest	Total protected
% of 1954 POG *	Alternative 5	65.3%	16.9%	0.8%	83.0%
	Alternative 6	66.2%	15.9%	1.1%	83.2%
% of 2006 POG	Alternative 5	71.0%	18.4%	0.9%	90.3%
	Alternative 6	72.0%	17.3%	1.2%	90.5%

* The % of 1954 POG is the % of POG that was present in 2005 compared to the amount of POG that was estimated to be present prior at the onset of large-scale timber harvest.

It is not possible to estimate how many goshawk nests will be found in the future within units in active timber sales under contract. However, it is likely to be a relatively rare circumstance; since 1997, this issue of has occurred only once, where the nest moved multiple times within the timber sale contract area.

There is no scientific basis in Southeast Alaska to support a management strategy for goshawks that relies on retaining a prescribed threshold of suitable habitat in matrix lands instead of having perpetual nest buffer protections, as was done for management of goshawks in the southwest. While such a strategy would ideally provide flexibility to address timber harvest and goshawk nest conflicts, there are no studies that guide development of a habitat threshold. Science supports that the retention of old growth in matrix lands is an important component of goshawk conservation, especially within biogeographic provinces that are anticipated to be at higher risk for goshawks because they do not maintain a 300-year ecological rotation (Iverson et al.1996). But there are no known thresholds for how much old growth can be harvested before goshawks will abandon a territory. However, as described in Iverson et al. (1996), one estimate of the minimum proportion of old growth in breeding use areas in Southeast Alaska was 23 percent for males and 28 percent for females, respectively. It is instructive to assess the quality and protection status of habitat around known nest sites on the Tongass. Such information supports that known goshawk nests, many of which have been found during timber sale planning and thus are in matrix lands, have a high degree of habitat protection.

During the 1997 Forest Plan process, stand-level analysis was conducted to examine past timber harvest at various spatial scales around known goshawk nests. It also examined additional future risk to known goshawk nesting areas compared to land allocations and standards and guidelines in the Forest Plan. A sample of 36 known goshawk nest areas in Southeast Alaska was used for this analysis. This sample of nests is biased towards goshawks discovered in landscapes predominantly allocated to timber management and may not necessarily be representative of the entire goshawk population in Southeast Alaska. Within this sample, relatively little POG had been harvested around known goshawk nests. The proportion harvested increased with distance from the nest, with 3 percent (range: 0 to 50 percent) within the 0.25 mile radius (radius area = 140 acres), 12 percent (range: 0 to 57 percent) within a 1-mile radius (radius area = 2,040 acres), and 14 percent (range: 0 to 61 percent) within a 3-mile radius (radius area = 18,000 acres). Only 2 of 36 nests (6 percent) had any harvest within the 140-acre area around the nest and only 60 acres within the 0.25 mile radius had been harvested after the nest was discovered. Similarly, only 160 acres at three nests had been harvested within a 1-mile radius once the nest was located.

In addition, this analysis indicated that a total of 20 of 36 (56 percent) goshawk nest sites known at that time occurred in a protected natural setting LUD. Nearly 40 percent of the entire area of all three spatial analysis areas (0.25-, 1-, and 3-mile radii from the nest) would be protected in a reserve in the Forest Plan, despite potentially being a biased sample toward landscapes predominantly allocated to timber harvest. This reiterates the importance of the non-development LUDs in the overall protection of goshawk nest sites.

A summary of recent research given at the Conservation Strategy Review Workshop (US Forest Service 2007) looked at hypothetical post-fledging areas (PFAs) around 78 known goshawk nests, which indicated that these contained, on average, 39 percent medium- and high-volume old growth, 45 percent productive forest, 8 percent low-volume forest and 4 percent clearcuts. Results of this hypothetical PFA analysis indicated that an average of about 40 percent of the PFAs were medium- or high-volume POG, of which 55 percent was in the development LUDs or non-National Forest System lands.

More detailed analysis was done for the Forest Plan amendment looking at the same issue of protection of habitat around known goshawk nests but included an assessment of two different sized hypothetical PFAs. Both measurements have similar results and therefore, the issue of the actual size or shape of the circle is probably not biologically meaningful. For a 1-mile radius circle, 27 percent of circle was protected POG, 13 percent was POG mapped as suitable for harvest, 10 percent was young growth, 24 percent was unproductive forest, 5 percent was non-forest, non-NFS lands was 14 percent (this land contains POG, young growth, unproductive forest, and non forest), and saltwater was 9 percent. However, this analysis was done using the mapped suitable POG. If the difference between as the mapped suitable and what is actually suitable on the ground (due to a variety of factors, such as steep slopes, new streams, and other standards and guidelines) and scheduled for harvest, the acres of POG protected would increase to about 31 percent of the circle and the acreage of POG not protected would decrease to about 9 percent of the circle.

All of these analyses indicate that goshawk nests on the Tongass are afforded a relatively high level of protection, including both nests that occur within non-development LUDs and those in the matrix lands of development LUDs. In most cases there would be other potential nesting habitat within the goshawk's territory if nest stand was inadvertently logged. The analysis described above is a potential future monitoring tool to see whether newly found goshawk nests in the matrix have similar conditions.

There is the risk that timber harvest will occur within an occupied or historic goshawk nest stand, given that goshawks do not always respond during surveys and thus, there is some risk of overlooking goshawks during timber sale planning. This risk exists with or without changing this standard. However, the risk is reduced during the entire process from planning to layout to contract implementation since stands are visited multiple times and, therefore, it is less likely that a truly occupied stand would be overlooked. In addition, the Tongass will continue to do goshawk surveys for timber sale planning prior to NEPA decisions.

Overall, at least 90 percent of existing POG would be protected or not be scheduled for harvest under either Alternative 5 or 6 after 100 years (assuming the maximum timber harvest levels allowed in these Alternatives). While there is some uncertainty in how many nest stands would be affected by this change in standard and guideline, given the degree of POG retention within goshawk territories in the matrix that provide potential habitat for both alternate nest sites and foraging habitat and that the vast majority of nesting habitat is protected over the life of the Plan, implementation of this standard may affect nest occupation by individual pairs but not substantially affect goshawk populations across the Tongass.

Overall, nest protection within the matrix, while an important component of the conservation strategy, is a relatively small component of the overall conservation strategy because timber harvest will occur within a small portion of suitable goshawk habitat. The U.S. Fish and Wildlife Service, in their 2007 finding (Federal Register 2007. Vol. 72 no. 216 pp. 63123-63140) acknowledged this issue of goshawk nest protections and concluded the following, which confirms the value of the key components of the conservation strategy for goshawks:

> "Nest buffers of 100 ac (40 ha) of POG, as specified in the Forest Plan, are intended to protect individual nests from disturbance. Larger buffers would likely enhance goshawk conservation by providing better habitat for fledglings in the immediate vicinity of the nest, but lack of larger buffers is not expected to reduce fecundity or survival to an unsustainable level because OGRs, which typically protect much larger patches of old growth forest, and other retained forest patches are reserved in each watershed, and we expect goshawks to nest in these reserves as the forest

around them is increasingly harvested. In some cases, suitable nesting habitat in nearby reserves may already be occupied by nesting pairs, but the territoriality of goshawks is likely to prevent this in most cases."

They also discuss concerns that have been raised about the adequacy of the conservation strategy to maintain goshawk populations and conclude that:

"In spite of the shortcomings discussed above, we find that the full suite of standards, guidelines, and land designations contained in the 1997 Forest Plan are likely to provide adequate habitat protection to sustain goshawks in Southeast Alaska into the foreseeable future, largely because adequate amounts of old and mature productive forest will be protected in reserves, retention areas, and inoperable stands, in large and small patches, throughout the harvested matrix. "

2.5.2.4. Landscape Connectivity – Alternatives 1, 2, 3, 4 (partially), & 6

The Forest-wide Landscape Connectivity standard and guideline was changed to clarify when the issue of connectivity was important to assess during project implementation. It was also changed given that changes in the small OGR boundaries have improved connectivity between all medium and large OGRs and no areas will need specific consideration during project implementation (see *Biodiversity* and *Wildlife* sections of the Final EIS).

The conservation strategy did not assume that there was connectivity between small OGRs and the mediums and large OGRs. Connectivity would be provided for by beach fringe, riparian buffers, other standards and guidelines, other unsuitable POG, and unscheduled POG. While it may be desirable to consider local connectivity issues within a project area during NEPA analysis, this is not necessary in order to provide for viable and well distributed populations – this was provided by the Forest-wide reserve network of old growth in non-development LUDs.

The other portion of this standard that was added was to consider young-growth treatments that accelerate old growth conditions on unsuitable acres. There are significant acres of young growth in non-development LUDs that could provide connectivity quicker with active management.

Under Alternative 4, this standard and guideline would only apply within the four biogeographic provinces that include small OGRs (see *Biodiversity* and *Wildlife* sections of the Final EIS).

2.5.2.5. Endemic Mammals – Alternatives 1, 2, 3, 4, 6, and 7

The Forest-wide Endemic Terrestrial Mammal standard and guideline was changed to clarify what kinds of information should be used for assessing endemic mammals during NEPA analysis. The standard allows for use of existing information on endemic mammals to be used for project planning where available. The Forest has invested significant funds into numerous cooperative projects with several universities as well as with the Pacific Northwest Research Station. The result of this investment is a significantly better understanding about mammalian distribution in Southeast Alaska, than existed prior to the 1997 Forest Plan (for example, MacDonald and Cook 2007). This is not to imply that we have information on species distributions on all islands of Southeast Alaska. However, on many islands, particularly the larger islands, there is adequate presence/absence data for NEPA analysis. There is some inherent risk to endemic mammals under all alternatives because of their inherent endemism, their distribution amongst islands, and the lack of complete knowledge of their distribution and habitat relationships.

Other guidelines added to the 1997 Plan in response to the panel assessments would also benefit both the endemic and widely-distributed mammals. The connectivity guideline will provide additional measures to maintain connectivity of large and small reserves and other non-development LUDs in places where beach fringe and riparian habitat management areas do not provide adequate connectivity. Guidelines for structural retention for goshawk and marten habitat as well as the legacy standard and guideline will also benefit other mammal species. The increased quality and quantity of the OGR system under Alternatives 1, 2, 3, and 6 will also benefit many endemic mammals, particularly those as most risk, which includes the Prince of Wales flying squirrel.

2.5.2.6. Marten – Alternatives 1, 2, 3, 4, 6, and 7

The American marten Forest-wide standard and guideline was changed to clarify when to consider road density management. The standard clarifies that consideration of access as an issue for marten management should only occur when it is demonstrated that mortality is exceeding sustainable levels and that the most significant factor causing this human access on roads.

This change does not change the intent of the standard; however, it clarifies when it should be implemented. Other minor edits were also done to this standard and guideline that do not change the intent of the standard, but clarify it for more consistent implementation.

2.5.2.7. Wolf – Alternatives 1, 2, 3, 4, 6, and 7

The Alexander Archipelago Wolf Forest-wide standard and guideline was changed to clarify when to consider road density management. It also incorporated information from the Conservation Strategy Review that indicated that both open and total road density were important factors to consider when assessing road effects on wolves. The standard clarifies that consideration of access as an issue for wolf management should only occur when it is demonstrated that mortality is exceeding sustainable levels and that the most significant factor causing this human access is roads.

This change does not change the intent of the standard; however, it clarifies when it should be implemented. Other minor edits were also done to this standard and guideline that do not change the intent of the standard, but clarify it for more consistent implementation. It continues to outline the need for a cooperative interagency analysis to identify regions where wolf mortality is apparently excessive. In such areas we would attempt to determine if the mortality is unsustainable and identify the probable causal factors of the excessive mortality. If road access and specific roads are identified as contributing to excessive mortality, then road closures or access management recommendations can be made and actions taken. In addition, seasons, harvest methods and bag limits need to be considered as population management tools by the ADF&G and Federal Subsistence Board as a cooperative approach to managing wolf mortality at a sustainable level.

The 1997 Forest Plan did not prescribe a rigid open road density limit and one is not proposed in this amendment. The Wolf Assessment Panel recommended not using a specific road density "rule of thumb." This was contrary to recommendations in Suring et al (1993) where a road density limits from 1 to 1.25 mile of open road per square mile were recommended, depending on geographic location. Establishing a rigid road density level was not done because the resulting arbitrary closure roads to meet this density was determined to provide no management assurance that wolf conservation objectives would be achieved. Furthermore, it could unnecessarily limit overall public use of an established road system that may otherwise have no specific adverse impact on wolf mortality. Management recommendations for road and access management, if necessary, would result from the site-specific analysis discussed above that would identify a problem requiring a local and cooperative management resolution. Road densities above or indeed below these referenced densities may be appropriate to effectively manage road-access related wolf mortality. This approach is also taken by the amended Forest Plan.

Changing the standard and guideline to consider total rather than just open road density takes into account updated science supporting the relationship between wolf mortality and both open and closed roads. The standard and guideline also retains a range of road densities, based on research from several locations, including Alaska, Minnesota, and other states, that guide managers to determine the need to take action to address wolf mortality concerns. Based on research described in Section 2.4.2.3, the risk of unsustainable wolf mortality is higher on islands with roads that connect to communities than islands with no roads or roads that do not connect to a community. Given this variability in risk, adopting a range instead of one number allows better consideration of more site specific management that directly addresses actual human use.

2.5.2.8. Elimination of Legacy and Goshawk/Marten Standards and Guidelines – Alternatives 4 & 7

Alternatives 4 and 7 were developed because of the need to evaluate alternatives that satisfied higher timber volume demand levels than the 2007 Forest Plan. As such, methods of increasing timber volume levels were evaluated that caused the least impact to the conservation strategy. The elimination of the requirement to leave legacy or reserve trees within harvest units, as prescribed by the Legacy and the Goshawk and Marten standards and guidelines, was one of the key methods identified. As noted above and in Section 3, neither of these standards and guidelines were assumed for the viability panel ratings.

2.5.2.9. Minimum 33 Percent POG Retention – Alternative 4

Alternative 4 is different from the other alternatives in that it identifies Old-Growth Habitat LUDs in only four biogeographic provinces (North Prince of Wales Island, Kupreanof/Mitkof, Dall Island, and Northeast Chichagof), in addition to several individual reserves (Myers Chuck, Lake Eva, Wright Lake) in other provinces. This concept was first analyzed under Alternative 6 in the 1997 FEIS. Overall, Alternative 4 includes only 393,360 acres of Old-Growth Habitat LUDs, compared with 1,182,424 acres for Alternative 5. In order to provide for a minimum level of POG in VCUs outside of these four provinces, a new standard would require that a minimum of 33 percent of POG be retained in each VCU that occurs outside of the four biogeographic provinces. However, this requirement would not have a major effect on POG retention because few VCUs would result in less than 33 percent POG retention and the majority of those that would occur within the four biogeographic provinces.

2.5.2.10. Reduction of Beach Fringe – Alternative 7

Additional modifications were made to the standards and guidelines under Alternative 7 to respond to public comments so that this alternative could provide a higher level of timber volume and improve timber sale economics, while minimizing effects on the conservation strategy. This item and the next two items fall into this category; however, the reduction of the beach fringe is the most significant. Under Alternative 7, the beach fringe buffer would be reduced from 1,000 feet to 500 feet from the shoreline. This concept was first analyzed under Alternative 2 in the 1997 FEIS. Because this low-elevation band typically contains larger trees, is more easily accessible, and adds a substantial amount of suitable forest land, this modification has a large effect on available timber volume and average timber sale economics. On the other hand, it would negatively affect many wildlife and plant species that use or inhabit beach fringe habitats more extensively than most other Tongass habitats, and would negatively affect old-growth connectivity.

2.5.2.11. Elimination of Class III Stream Buffers – Alternative 7

As noted in Section 2.5.2.10, additional modifications were made to the standards and guidelines under Alternative 7 to respond to public comments so that this alternative could provide a higher level of timber volume and improve timber sale economics, while minimizing effects on the conservation strategy. The elimination of the requirement to leave riparian buffers along Class III streams is one of these modifications. It would not produce a substantial additional timber volume, but could result in more economic timber sales, since Class III stream buffers are thought, by many, to be a key factor in timber sale economics.

2.5.2.12. Elimination of Goshawk-Specific Nest Buffer Standard and Guideline – Alternative 7

As noted in Section 2.5.2.10, additional modifications were made to the standards and guidelines under Alternative 7 to respond to public comments so that this alternative could provide a higher level of timber volume and improve timber sale economics, while minimizing effects on the conservation strategy. Elimination of the goshawk-specific nest buffer standard and guideline is another modification that contributes to this goal. Only the general heron and raptor nest protection standard and guideline would apply to confirmed or probable goshawk nests. This means that active nests would receive forested 600-foot wind-firm buffers, where available, and that road construction through the buffer would be discouraged. Disturbance during the active nesting season would be prevented and protection measures could be removed if the nest is inactive after 2 consecutive years of monitoring.

3. WILDLIFE VIABILITY RATINGS

3.1. Historical Background for Tongass Viability Ratings

Direction under the National Forest Management Act (36 CFR 219.19:43048) states that “fish and wildlife habitat shall be managed to maintain viable populations of existing native and desired non-native vertebrate species in the planning area.” For planning purposes, a viable population is defined as “one which has the estimated numbers and distribution of reproductive individuals to insure its continued existence is well distributed in the planning area.” Furthermore, “habitat must be provided to support, at least, a minimum number of reproductive individuals and that habitat must be well distributed so that individuals can interact with others in the planning area.”

To meet these requirements, decision-makers for the 1997 Forest Plan revision effort relied in part on the findings of structured risk assessment panels, consisting of subject matter experts. The panels were charged with the task of providing unbiased scientific information on the relative risk associated with implementing each plan alternative to the continued persistence across the landscape of selected species or species groups. These risk assessment panels consisted of four evaluators (drawn from various Federal agencies and Alaska state government), a local subject matter expert available as a resource person, a facilitator, a scribe, and a silent observer (Shaw 1999).

The approach of using professional judgment to assess viability risk had been used in the Pacific Northwest for the development of the Northwest Forest Plan (FEMAT 1993, Starkey 1998). In addition, this approach was selected for the Tongass because of the considerable uncertainty regarding the ecology and distribution of many wildlife species and there was generally inadequate information on which to base predictive models. In addition, the timeframe for the planning process was too short to facilitate the collection of additional data on which to base predictive models (Shaw 1999).

Thus, seven wildlife panel assessments were conducted: one for goshawk, marten, brown bear, wolf, marbled murrelet, "other terrestrial mammals," which included both endemics and widely distributed species, and black-tailed deer. These old-growth associated species and species groups were selected because collectively their ecologies incorporated the breadth of forest habitat features and other attributes of environmental variation represented across the Forest (Shaw 1999)., and because they were thought to be representative of a subset of species that are sensitive to disturbance and potentially at risk of either becoming locally extirpated or jeopardizing cultural or subsistence uses. Risk assessment panels were also conducted for sustainability of the fisheries resource, old-growth forest ecosystems, the social and economic values of forest resources to residents of southeast Alaska, and subsistence use of forest resources (e.g., black-tailed deer and salmon), but these are not discussed further in this appendix.

Panel assessments were initially conducted in fall 1995 and winter 1995-96 to evaluate the risks of nine draft Forest Plan alternatives. Following public comment, and taking into account results of these panel assessments, some plan alternatives were modified and additional plan alternatives were developed that were not subject to the panel assessment process. Consequently, a second set of risk assessment panels was convened in the spring of 1997, which evaluated seven alternatives including a modified version of Alternative 2 (equivalent to 2008 Alternative 7) and a new Alternative 11 (equivalent to 2008 Alternative 5); Alternative 6 (similar to 2008 Alternative 4) was not reevaluated. Evaluators were the same during both panel assessments for the marten and the other terrestrial mammals group, but one or more evaluators changed for the other panel assessments.

In the 1997 FEIS, which was developed before the second set of panels was conducted, Alternatives 10 and 11 were not subjected to risk assessment panels as were the full array of draft alternatives. In the description and analysis of panel results in the 1997 FEIS (Chapter 3, *Biodiversity* and *Wildlife* sections), there was a strong correlation between the acres of POG scheduled for harvest in an alternative and the mean outcome scores for that alternative. As the number of acres harvested increased among alternatives, the mean outcome scores also increased, resulting in greater risk that habitat may not be sufficient to maintain viable and well distributed populations.

Based upon this strong relationship that emerged, the likely effects of Alternatives 10 and 11 were inferred from the acres of old-growth forest scheduled for harvest in these two alternatives, the features of these alternatives as compared to the paneled alternatives, and the relative importance of these features as judged from panel discussions for individual species. Using this approach the likely effects of Alternatives 10 and 11 were discussed in the *Biodiversity* and *Wildlife* sections of the FEIS. Because this strong relationship facilitated development of an effects analysis and time and expense of reconvening all panels was a consideration, alternatives 10 and 11 were not originally subjected to panel risk assessment.

To examine if these inferences were appropriate and presented an accurate analysis of likely effects of implementing Alternatives 10 and 11. This second set of six risk assessment panels included the northern goshawk, Alexander Archipelago wolf, brown bear, American marten, fisheries resources, and other terrestrial mammals. These panels followed the same process as the panels conducted in late 1995 and early 1996. The conclusions from this second set of panels were consistent with the inferences made based on the strong relationship between acres harvested and viability scores (see Appendix N to the 1997 FEIS).

Therefore, this same approach for making inferences is being used in the 2008 Forest Plan Amendment FEIS. Additional factors which solidify the accuracy and reasonableness of this approach are that all of the 2008 alternative harvest levels are within the range of harvest levels analyzed by the panels and four of the seven 2008 alternatives are similar to alternatives directly evaluated by the panel assessments.

Section 3.2 describes the 1995/1996 and 1997 panel assessment process and Section 3.3 summarizes the wildlife panel assessment results. Section 3.3 reviews recent science related to viability analysis and Section 3.4 describes the application of the 1995/1996 and 1997 panel assessments to the 2008 alternatives. Finally, Section 3.5 presents an alternative approach to addressing viability.

3.2. Description of the 1995/1996 and 1997 Panel Assessment Process

3.2.1. Panel Process

The panel assessments evaluated alternatives in terms of their ability to maintain habitat sufficient to support the continued existence of well-distributed, viable wildlife populations across the Tongass over a 100-year planning horizon (10 decades of implementation). The panels were conducted with a modification of the Delphi process that was used, tested, and judged effective in the President's Northwest Forest Plan.

To assess relative levels of risk to wildlife species or species groups, a likelihood approach was used where evaluators individually assigned 100 "likelihood" points by alternative to five potential outcomes, based on the available scientific information. Outcomes included:

- Outcome I: Habitat is of sufficient quality, distribution, and abundance to allow the species to maintain well-distributed breeding populations across the Tongass. The concept of well distributed must be based on knowledge of the species' distributional range and life history.
- Outcome II: Habitat is of sufficient quality, distribution, and abundance to allow the species to maintain breeding populations distributed across the Tongass. However, some local populations are more ephemeral because of reduced population levels and increased susceptibility to environmental extremes and stochastic events associated with reduced habitat abundance and distribution. Vacated habitats may become recolonized in the future.
- Outcome III: Habitat is of sufficient quality, distribution, and abundance to allow the species to maintain some breeding populations, but with significant gaps in the historic distribution in the Forest. These gaps are likely permanent and will result in some limitation of interactions among local populations. The significance of gaps must be judged relative to the species' distributional range and life history.

- Outcome IV: Habitat only allows continued species existence in refugia, with strong limitations on interactions among local populations. The significance of extirpations across islands or regional landscapes must be evaluated relative to the species' distribution, range, and life history.
- Outcome V: Habitat conditions result in species extirpation from Federal land.

Likelihood points assigned to these outcomes do not represent absolute probabilities per se, rather they represent a relative measure of how likely future outcomes are, based on reasoned professional judgment (Shaw 1999). Thus they can be used to compare alternatives, and serve as a measure of the evaluators' certainty about a particular outcome, but by themselves do not represent the percent probability of a given outcome.

For each species, evaluators independently assigned outcome scores to each alternative. For the endemic and widely distributed groups, evaluators selected what they determined to be the most vulnerable species or group of species, which varied by alternative due to the location of activities proposed under each alternative and the geographic distribution of many island endemics (Shaw 1999). However, like the single-species panels, each group was assigned only 100 points per alternative. The only species for which likelihood ratings were not used was the Sitka black-tailed deer, for which the panel assessment relied on the deer habitat capability model to predict potential outcomes (See *Wildlife* section in Chapter 3 for a description).

Panel evaluators were instructed to evaluate the effect that implementation of the alternatives for 100 years would have on the abundance and distribution of habitats suitable to support well distributed and persistent populations of species assessed. One hundred likelihood outcome points were distributed among five possible outcomes. In addition, panel evaluators were asked to appraise features used to construct alternatives (e.g., reserves, beach buffers) as to their contribution to maintaining habitat for species assessed. These qualitative appraisals of specific features and the panel discussions were used by the authors of the written summaries prepared for each panel, to interpret the quantitative evaluation of alternatives as indicated by the assignment of likelihood points by outcome and to identify important ecological considerations. (Summary reports for each panel were developed and are included in the planning record and at http://www.fs.fed.us/pnw/tlmp_app/.)

In the presentation of panel assignment of likelihood outcome points in each table below, the 'after' likelihood outcome ratings are used to compare among alternatives since these second ratings benefit from professional interaction and a likely greater understanding of differences among features in alternatives. The 'before' ratings occurred following presentations on alternatives and local information on each species, but before the merits of individual alternatives were discussed among panel evaluators. The average rating for all panelists also is used, rather than focusing on differences among individual evaluators.

3.2.2. Concepts of Viable and Well Distributed Populations

In the discussion and analysis of the first set of panel results in the 1997 FEIS, Outcomes I and II were often combined as an expression of likelihood of sustaining habitat sufficient to support viable and well distributed populations. Conversely, Outcomes III, IV, and V were often combined in effects analysis as representing increased risks of not maintaining the habitat necessary to sustain viable and well distributed populations. By virtue of its description, Outcome III was difficult to interpret due to the statement that "significant gaps" would be created and the "significance of gaps must be judged relative to the species distributional range, and life history." There was considerable variability in the interpretation of this concept by individual panelists. The original panelists convened in late 1995 and early 1996 were not specifically queried about the relationship between outcomes and the maintenance of viable well-distributed populations. These conclusions were generally inferred, based largely upon whatever discussion occurred during panel deliberations. In general, the IDT inferred that Outcome III represented a condition where gaps were significant enough to substantially preclude interaction among populations of the species. In this condition, a species would not be well distributed, and continued existence of the species across the planning area would be at risk.

Because of the difficulty the IDT encountered in interpreting the first set of panel results relative to the maintenance of well distributed and viable populations, the second set of panelists were provided an opportunity to directly and explicitly discuss these issues. The same five outcomes were used in the second panels conducted in 1997. However, focused discussion provided additional information relative to Outcome III and the panelists' interpretation of gaps in distribution, well distributed populations, and viability.

Outcome III, defined as providing habitat to maintain breeding populations but with significant gaps in historic distribution, was interpreted as an array of conditions. For some of the panels, one end of this array was any condition where gaps in habitat existed as small as the territory of a single animal or single pair of animals of the species being assessed. At the other end, this array could include conditions with broad gaps in habitat distribution and significant limitations on population interactions. The panelists considered some part of this array of conditions as meeting their concept of viable and well distributed. They indicated that the concepts of well distributed and viable, as they used them for the purposes of assessing risk, were not necessarily synonymous. Their views on well distributed habitat dealt primarily with the likelihood that modified habitat would, because of gaps, no longer be able to support a continuous territory-to-territory distribution of resident individuals or groups. That is, some previously occupied territories might become permanently vacant within a 100-year timeframe.

The panelists interpreted viability as a condition in which populations could continue to interact and interbreed within their historic distribution across the Tongass National Forest. They felt that a distribution that included some gaps could still be considered viable as long as there was still interaction among the population segments on the forest and those population segments were distributed across the species range. For example, the marten panel understood that their concept of a habitat gap being as wide as a previously occupied home range likely had little if any effect on species interaction or interbreeding. Thus, in the panelists' interpretation, the criterion of well distributed was more restrictive than the criterion of viable.

The panelists were not providing a legal interpretation of the requirement in the National Forest Management Act of 1976 (NFMA) regulations to provide for viable populations. In the discussion of population viability in the NFMA regulations, the concept of "well-distributed" is tied to the ability to continue interactions among individuals of a species, not necessarily to the maintenance of a territory-to-territory distribution of the species. The interpretation of well distributed is expressed most clearly in the stipulation that maintenance of a viable population requires providing habitat to support "at least a minimum number of reproductive individuals and that habitat must be well distributed so that those individuals can interact with others in the planning area" (36 CFR 219.19). This has been interpreted to mean that the condition of viable and well distributed allows for gaps within a species distribution as long as the population segments of the species continue to interact and are distributed throughout the planning area. Thus, the concept of well distributed used by the panelists was more stringent than the concept as applied in the NFMA regulations.

It is difficult to determine how many likelihood points were assigned to the outcome of a viable population since the panelists considered that only some part of the array of conditions under Outcome III met their definition of viable. Thus, the likelihood of maintaining habitat sufficient to support well distributed and viable populations is appropriately presented as being within the span of scores that bracket Outcome III. Consequently, in some of the tables in the following discussions, ratings are expressed as being greater than the sum of likelihood scores for Outcomes I and II, but less than the sum of likelihood scores for Outcomes I, II and III. Expression of data as a range also illustrates the uncertainty in the process and the variability in the professional judgments regarding the concepts of viable and well distributed populations. Use of a range also avoids presenting a single absolute value that might suggest a level of precision that does not exist in this assessment process.

Finally, in some of the following tables, 1995/1996 panel outcome scores are expressed in the same manner of bracketing scores as for the 1997 scores discussed above. Expression of the first panel information in this manner is for comparative purposes only. These combinations do not infer any conclusions on behalf of the 1995/1996 panels because they did not specifically discuss viable and well distributed populations relative to the specific outcomes.

3.3. Summary of 1995/96 and 1997 Panel Assessment Results for Wildlife

3.3.1. Northern Goshawk

3.3.1.1. General Observations on the Goshawk Panels

Panelists noted the apparent low relative density of nesting goshawks in Southeast Alaska. Less than 40 total nest sites had been identified by the time of the assessments after nearly 5 years of inventory effort across the Forest (Iverson 1996a). Low prey diversity compared to other goshawk populations across North America was considered a principle factor, resulting in a higher sensitivity to habitat modifications which may reduce prey diversity and abundance.

The primary factor used by panelists in rating the likelihood of alternatives to support a viable and well-distributed goshawk population was net proportion of all old growth on the Tongass that would be harvested in 100 years (Iverson 1996a, 1997a). This was based on science current at the time of the panel assessments that indicated the strong selection by goshawks for POG forest and the avoidance of all other habitat types (especially early and mid seral conifer forests), though panelists noted that the reliance on this factor was somewhat general due to the lack of more specific information on goshawks in Southeast Alaska and what specific old-growth acres would be harvested.

The 1995 panel assessment used 20 percent of the POG harvested as a threshold level beyond which local persistence and viability were concerns (Iverson 1996a). Most notable was north Prince of Wales Island where in excess of 20 percent of the POG had been harvested. Significant concern arose over this and increased proportions of unsuitable early seral forest on the landscape. This concern was generated from the relatively low density of nesting goshawks discovered relative to the inventory effort in those landscapes. In addition, potential signs of ecological stress was indicated by large home ranges, nonbreeding, and differential winter and breeding use areas. Thus, qualitative judgments concluded that alternatives resulting in this or a greater percentage of the net POG harvested could result in negative overall landscape consequences to sustaining resilient, adaptable, and well distributed goshawk populations in Southeast Alaska. While such thresholds were considered by the 1997 panel, they did not make any conclusions regarding harvest thresholds due to the lack of information and other uncertainty (Iverson 1997a). They suggested that to draw conclusions relative to harvest thresholds, further information was needed on the demographic performance of goshawks under different situations.

In addition, alternatives that proposed standards and guidelines to maintain important landscape components such as riparian, beach and estuary buffers were rated as having higher likelihoods of supporting well-distributed goshawk populations. These habitats are used by goshawks when old-growth forest is present and they also generally support greater prey diversity and net prey productivity. The ability of stands to provide structure adequate to support prey populations and goshawk foraging opportunities was also considered important and related to the length of rotation and harvest method proposed under the alternatives.

The concept of habitat reserves was seen as a less important landscape design feature, since management of the landscape matrix as a whole was felt to have a greater net influence on goshawk habitat suitability, distribution and persistence. Large (40,000 acre) and medium (10,000 acre) habitat reserves as proposed were generally considered too small to sustain more than one or two pairs of goshawks. Roads were not considered an adverse element, thus roadless features of reserves did not generally contribute to overall habitat suitability.

Panelists concluded that at some, albeit low, minimum level, forest management was not considered adverse to overall goshawk habitat suitability and likely contributed to stand diversity.

Given the wide ranging nature of goshawks, the panels emphasized the importance of matrix management to providing habitat capable of supporting viable and well-distributed goshawk populations. However, elements of the reserve system (i.e., large and medium habitat reserves and legislated conservation areas) were deemed important because by default they reduced the net acreage of old-growth harvested.

3.3.1.2. Goshawk Panel Results

The final average panel ratings for northern goshawk are displayed in Table D-9. Alternative 1 in 1997 essentially represents a no-harvest alternative. Nearly two-thirds of all likelihood points were assigned to Outcome I, which indicates that well distributed goshawk breeding populations would be maintained across the Tongass. However, Outcome II received nearly a third of likelihood scores, suggesting that even with no further reduction in old-growth forest, goshawk populations would likely experience reductions and local persistence may be more ephemeral or irregular as a result of the local concentration of habitat loss from past timber harvest. Implied in this conclusion is that additional harvest would be additive to an existing effect.

Because of the significant amount of legislatively reserved lands and the net amount of POG that would likely remain under even the most aggressive timber harvest alternatives, panelists believed there was little chance for total extirpation of the goshawk population from Southeast Alaska. The highest rating for Outcome V (extirpation) was only 8 (for 1997 Alternative 7). Moderately high net scores for Outcomes I and II occurred for 1997 Alternatives 4 and 5 (65 and 74-85, respectively). These alternatives had in common the use of extended 200-year rotations. Panelists generally believed that forest structure resulting from mid-seral mature forest developmental stages (100 to 200 years old) was more beneficial to goshawks and their prey than a combination of reserves and shorter, 100-year rotations.

The 1997 panel assigned 71 likelihood points to 1997 Alternative 11 for the sum of Outcomes I and II, and 97 likelihood points to the sum of Outcomes I, II and III. Even though this alternative was based on a 100-year rotation, its ratings were second highest of all alternatives that proposed to continue timber harvest, only slightly lower than the rating given to Alternative 5. In addition, Alternative 11 was rated as having very low likelihood of goshawks existing in refugia or being extirpated from the Tongass after 100 years of Forest Plan implementation with a combined Outcome IV and V score of 3.

Alternatives 3, 6, and 10 (1997) had intermediate combined Outcome I and II scores of 52, 50, and 48, respectively. In spite of partial or complete application of habitat reserves, the higher overall old-growth harvest levels, coupled with the 100-year rotation perpetuated a less suitable early seral forest stand structure and was a drawback for these alternatives. Conversely, panelists attributed moderate uncertainty that either of these two alternatives would maintain well distributed populations, with a combined score of Outcomes III, IV and V of 48 (1997 Alternative 3), 50 (1997 Alternative 6), and 53 (1997 Alternative 10). This suggested there was a nearly even chance that either permanent gaps in the distribution would occur or goshawks may exist only in refugia under these three alternatives in 100 years; and in either case interaction between individuals would likely diminish. The forest-wide system of old-growth habitat reserves proposed in 1997 Alternatives 3 and 10 alone imbedded in a matrix of early seral forest structure managed on a 100-year rotation were rated by the panelists to be of insufficient size to support goshawk populations without gaps in distribution or refugia populations occurring.

Alternatives 2, 7 and 9’ (1997) were rated by panelists as having a relatively high likelihood (76-80, 88, and 77-92, respectively) that in 100 years gaps in distribution would be likely to occur or populations would exist only in isolated refugia or be extirpated (Outcomes III, IV, or V). When Alternative 9 was analyzed in 1997 with a lower harvest, results were nearly the same producing a likelihood of 90.

Variation in ratings for alternatives assessed in both 1995 and 1997 ranged up to 18 points based on the sum of likelihood points assigned to Outcomes I, II and III (Table D-9). Of those alternatives reviewed in both 1995 and 1997, 1997 Alternatives 1, 5, 2, and 9' were ranked in order (based on average weighted outcomes) from least to highest risk to goshawk habitat in both of the assessments. The 1997 panels also confirmed the judgment in Chapter 3 of the 1997 FEIS, based on a detailed analysis of VCUs, that 1997 Alternatives 5 and 11 had the highest likelihood of sustaining goshawk habitat across the forest of all alternatives that proposed to continue timber harvest. However, the analysis in Chapter 3 resulted in a conclusion that 1997 Alternative 11 had a slightly higher likelihood of maintaining goshawk habitat than 1997 Alternative 5.

[1] Mean likelihood outcome scores by evaluators in 1997 are shown at the top of the table. Scores from the 1995 panel are shown in the middle of the table. Scores were assigned by both panels for Alternatives 1, 2, 5, and 9’. Alternatives 1 and 9’ are identical between panels in both features and acres of POG harvested. Alternatives 2 and 5 are identical in features but with fewer acres of POG harvested in 1997 relative to 1995. A range for all alternatives is shown at the bottom of the table for the likelihood of maintaining habitat to support viable and well distributed goshawk populations. Only ‘after’ scores are shown. The - 414,000 value for POG harvest under Historic represents the acreage harvested since 1954.

3.3.1.3. Effects of Added Habitat Management Measures

Even though 1997 Alternative 11 was rated second highest in terms of viability among all alternatives that proposed to continue timber harvest and had a very low likelihood of goshawks existing in refugia or being extirpated from the Tongass after 100 years of Forest Plan implementation, because it was the selected alternative and because the goshawk had been considered for listing under the Endangered Species Act, 1997 Alternative 11 was reviewed to determine if features of the alternative could be modified to improve the projected outcome.

The conservation assessment for northern goshawk (Iverson et al. 1996) evaluated the effect of various management practices on goshawk nesting and foraging habitat, and also identified specific geographic locations where goshawk habitat had been highly fragmented. Based on this information, an additional measure for goshawk habitat was prescribed for Prince of Wales Island where POG had been fragmented by past management actions. This measure applied in VCUs where over 33 percent of POG had been converted to young stands by past management. In those VCUs, any additional management of POG was to be either restricted to 2-acre clearcuts or be managed to leave significant structure in harvested stands.

This standard and guideline applied to management activities in VCUs on Prince of Wales Island with a high percentage of past harvest. Approximately 55 percent of the total original POG had been converted to young forest in these VCUs. For any additional harvest of POG in these VCUs, the standard and guideline had the effect of either implementing a 200-year uneven-aged management regime or leaving structure equivalent to 30 percent of the cover of the original stand. Neither of these practices was expected to produce high-value nesting habitat, but they were expected to result in moderate to high value foraging habitat (Iverson et al. 1996). This structure, in combination with matrix management provisions for beach fringe and riparian management areas, was believed to facilitate goshawk dispersal among large and medium reserves on Prince of Wales Island. Goshawks were also considered to benefit in other provinces by the measures put in place for marten and for connectivity. Again, these had the effect of facilitating dispersal among goshawk populations in reserves. Taken in combination with other measures already in place in 1997 Alternative 11, these increased the already high likelihood of providing habitat sufficient to maintain viable and well-distributed goshawk populations and, had they been added prior to the panel assessments, may have increased the likelihood points.

3.3.2. American Marten

3.3.2.1. General Observations on the Marten Panels

Forest structure at the stand scale and integrated across the landscape was the most important factor in panel ratings and discussion due to the close association of marten with lower elevation and higher volume old growth and because these stands have also received a disproportionate amount of timber harvest (Iverson 1996b, 1997b). Structural complexity, associated with older forest stands, was also deemed important for providing habitat to support adequate prey populations of small mammals. The ability of alternatives to provide structural complexity was related to the proposed harvest rotation, which was a primary factor in the panel ratings. The panels considered 100 years an inadequate amount of time to produce structural elements such as large trees, snags, and downed logs that are used by marten and provide prey habitat. Maintaining the old-growth forest within the beach and riparian habitat zones was considered important by panelists, particularly for landscape connectivity and prey habitat diversity.

Both marten panels agreed that large and medium reserves as designated by the VPOP provide important habitat features for marten (Iverson 1996b, 1997b). Both panels indicated, however, that the VPOP approach to establishing a system of well distributed OGRs was only minimally acceptable for marten. The approach was judged to be minimal primarily because its spatial distribution of reserves could allow for the creation of “gaps” in marten distribution within harvested matrix lands.

Roads were a minor consideration in panel ratings in relation to their impact on human access. As with wolves, it was not the direct effect of the number of road miles or road density proposed under the alternatives, but rather increased trapping pressure and related mortality resulting from increased access which could be mitigated through appropriate road management, seasons, and bag limits.

3.3.2.2. Marten Panel Results

The final average panel ratings for American marten are displayed in Table D-10. Alternative 1 (1997) provided the greatest likelihood of maintaining well distributed marten populations across their current range on the Tongass. It had a mean likelihood rating of 54 (in 1995) to 84 (in 1997) for Outcome I. The 1995 panelists indicated that even with no further timber harvest and road construction, there was still a reasonable likelihood that local populations would be reduced or gaps that limit populations would be created with little interaction within the species range, as indicated by a combined score of 46 for Outcomes II and III. Concentration of past timber harvest in specific provinces and past harvest primarily in the high-volume classes which were concentrated at lower elevations contributed to this conclusion. In contrast, however, the much higher ratings given by the 1997 panel indicated they thought that past timber harvest would create few gaps in marten distribution (combined score of only 17 for Outcomes II and III).

Panelists concluded that there was no likelihood of extirpation of marten from the entire Tongass National Forest under all alternatives in 1997 and under most alternatives in 1995. In 1995, Alternatives 2, 9, and 7 were considered to have some chance of extirpation (likelihood scores of 15-25 for Outcome V). Anticipated timber harvest, especially in the remaining high-volume class stands at lower elevation, and road construction, contributed to this conclusion.

The likelihood that in 100 years an alternative would result in either significant gaps in distribution, populations existing in relatively isolated refugia, or local extirpations, may be an indication that marten populations would not remain well distributed across the forest. This cumulative likelihood is the sum of Outcomes III, IV, and V. From this perspective, 1995-1997 Alternatives 2, 7, 8, 9 and 9’ were given cumulative ratings of 80 to 91, depending on the panel and the alternative. Alternative 6 (1995) also had a relatively high cumulative likelihood outcome of 72. Extensive planned roading, continued fragmentation of habitat, and most importantly, a significant reduction in the important high-volume old-growth forest component were factors cited by panelists that contributed to these conclusions. Even (1995-1997) Alternatives 3, 10, and 11, with their significant reserve components had combined Outcome III, VI, and V ratings of 56 to 70, suggesting a better-than-even chance that well distributed populations may not be maintained across the Tongass in 100 years. All of these alternatives had in common a 100-year timber harvest rotation.

Alternatives 4 and 5 (1995-1997) were rated intermediate by the panelists in their likelihood of maintaining persistent and well distributed marten breeding populations, with combined scores for Outcome I and II of 60 and 66-70, respectively. Extended 200-year timber harvest rotations was the most important design feature for sustainable approaches to providing marten habitat.

Alternative 10 (1997) was intermediate between 1997 Alternatives 2 and 3 in both design features and acres of old growth harvested; thus risks to maintaining viable marten populations were considered intermediate between these two alternatives. In spite of having a system of large, medium and unmapped small reserves that would reduce risks relative to 1997 Alternative 2, the 100 year rotation, only a 500-foot beach fringe, and smaller riparian buffers in 1997 Alternative 10 was considered as possible long-term risks to marten.

[1] Mean likelihood outcome scores by evaluators in 1997 are shown at the top of the table. Scores from the 1995 panel are shown in the middle of the table. Scores were assigned by both panels for Alternatives 1, 2, 5, and 9'. Alternatives 1 and 9' are identical between panels in both features and acres of POG harvested. Alternatives 2 and 5 are identical in features but with fewer acres of POG harvested in 1997 relative to 1995. A range for all alternatives is shown at the bottom of the table for the likelihood of maintaining habitat to support viable and well distributed goshawk populations. Only 'after' scores are shown. The - 414,000 value for POG harvest under Historic represents the acreage harvested since 1954.

Alternative 11 (1997) had additional features that further increased the likelihood of maintaining viable goshawk populations relative to 1997 Alternative 3, such as mapped small reserves in all watersheds, and allocation of four additional medium and small reserves. The 1,000-foot beach and riparian protection were similar among 1997 Alternatives 11 and 3, but 1997 Alternative 11 had substantially fewer old growth acres scheduled for harvest (475,000) and thus lower risk than 1997 Alternative 3 (571,440). Total acres harvested in 1997 Alternative 11 was even fewer than 1997 Alternative 4 (495,000), in spite of the 200-year rotation. Alternative 11 (1997) did not have a two-aged silvicultural prescription that maintained forest structure considered important by panelists, but the net acres old growth disturbed might have offset either the potential advantage of two-aged management in 1997 Alternative 3 or two-aged management and a 200-year rotation in 1997 Alternative 4.

Of those alternatives reviewed in both 1995 and 1997, Alternatives 1, 5, 2, and 9' were ranked in order from least to highest risk to marten habitat in both assessments (Table D-10). The 1997 panel results also were consistent with conclusions drawn concerning the relative ranking of all alternatives based on other evidence in Chapter 3 of the 1997 FEIS and other information in the planning record. This includes the conclusion that outcomes of 1997 Alternative 11 would be similar to those of 1997 Alternative 3.

3.3.2.3. Effects of Added Habitat Management Measures

American martens were one of the primary species considered in the design of the original VPOP strategy. By design, each large HCA was intended to support at least 25 female martens, medium HCAs to support at least 5 female martens, and small HCAs at least 1 female. Each large HCA was designed to support a population with high likelihood of at least short-term persistence. The design distance between large HCAs was 25 miles, approximating the maximum dispersal distance recorded for marten, and medium and small HCAs were spaced more closely. Forested corridors were to provide for dispersal among HCAs. All corridors were to be at least 330 feet wide, and riparian and beach fringe habitats were considered appropriate corridors where they provided connections among the HCAs. This network of interconnected HCAs was intended to support a number of local populations that could interact as a metapopulation, thus providing for long-term viability.

Three of the scientists involved in the Kiester and Eckhardt (1994) review identified limitations in this strategy for marten. Benkman, Lidicker, and Powell questioned the use of the maximum marten dispersal distance to establish spacing among HCAs. Benkman cautioned that this strategy would only work if the medium and small HCAs provided connections among the large HCAs. Lidicker added that the condition of the matrix ought to be considered when establishing distances among HCAs. Powell indicated that marten would generally not travel directly between HCAs, so the actual distances they would have to cover would exceed the design distance. None of these reviewers commented directly on the size of large or medium HCAs, but both Benkman and Powell noted that the small HCAs would be unlikely to support even one pair of marten by themselves. A number of the reviewers in Kiester and Eckhardt (1994) commented in general that the utility of corridors for wildlife dispersal had not been demonstrated. None of these comments were specific to marten, possibly because marten are known to make extensive use of riparian zones (Bissonette et al. 1989, Clark et al. 1987).

The VPOP strategy is most fully represented in 1995-1997 Alternative 3. The risk assessment panel convened in 1995 rated this alternative intermediate between 1995 Alternative 1 (no further harvest) and 1995 Alternative 9 (continuation of the existing plan). They indicated that there was a better than equal likelihood that implementation of this alternative for 100 years would result in significant gaps in marten habitat distribution on the Tongass. They projected no likelihood that marten would be extirpated from the entire forest under this alternative.

The risk assessment panel convened in 1997 gave Alternative 11 a similar risk rating to that given to Alternative 3 in 1995. Alternative 11 (1997), as rated by the panel, provides for a wider beach fringe buffer than 1997 Alternative 3, but it also relies more heavily on even-aged management in the matrix. Panelists noted that the projected matrix conditions had a significant influence on their ratings. The panelists convened in 1997 also clarified their interpretation of the outcomes that were used as the basis for risk assessment. Outcome III, defined as providing habitat to maintain breeding populations but with significant gaps in historic distribution, was interpreted as an array of conditions. At one end of this array was any condition where gaps in habitat existed as small as the territory of a single marten. At the other end, this array could include conditions with broad gaps in habitat distribution and significant limitations on population interactions. The panelists considered some part of this array of conditions as meeting the definition of viable and well-distributed. The panelists assigned a total of 91 likelihood outcome points to the sum of Outcomes 1 + II + III. This included 36 likelihood points in Outcomes I and II, which they considered to represent a viable and well distributed condition. It also included 55 likelihood points in Outcome III, some portion of which represents a viable and well distributed condition. The panelists indicated there was a very low likelihood that marten would exist only in refugia or be extirpated from the Tongass after 100 years of Forest Plan implementation with a combined Outcome IV and V score of 9. The panelists indicated that matrix management was the feature of 1997 Alternative 11, as rated, that contributed to the assignment of likelihood points to outcomes that were not well-distributed. They indicated that clearcut silviculture on a 100-year rotation would result in further fragmentation of marten habitat.

Alternative 11 (1997) was strengthened subsequent to the panel assessment because that assessment indicated a level of concern about the likelihood of marten populations remaining well-distributed across the Tongass for at least 100 years. The measures used to strengthen the alternative were based on comments provided by the panelists, information drawn from past studies on marten, and information on existing habitat conditions on the Tongass. Three different measures were applied to 1997 Alternative 11 to improve the likelihood of maintaining habitat to support well-distributed populations of marten.

The first directs the management of high quality marten habitat in five biogeographic provinces where marten habitat was considered to be at higher risk. These five biogeographic provinces were identified by the VPOP risk assessment as the highest risk provinces of the 21 provinces across the Tongass National Forest (Suring et al. 1993). High value habitat is defined in the Interagency Marten Habitat Capability Model (Suring et al. 1993) as consisting of high-volume old-growth stands at elevations below 1,500 feet. Within the high-risk provinces, these stands were to be managed under practices other than clearcutting. In VCUs where 33 percent or more of the POG had been or was projected to be harvested, further harvest in any high-value marten habitat would retain at least 30 percent canopy closure, 8 large live trees per acre, 3 large decadent trees per acre and 3 logs per acre. Where less than 33 percent of POG had been harvested, further harvest in high-value marten habitat would retain 10-20 percent canopy closure, 4 large live trees per acre, 3 large decadent trees per acre, and 3 logs per acre. These habitat management measures were based on studies showing marten use higher in partially logged areas than clearcut areas (Soutiere 1979); a study reported by Hargis and Bissonette (1997) and Hargis et al. (1999) indicating that the proportion of clearcut harvesting at a landscape scale is a key determinant of marten success; and numerous studies showing the importance of large wood structure to marten (Baker 1992, Buskirk et al. 1989, Corn and Raphael 1992, Raphael and Jones (1997).

The second measure provided for access management to reduce marten mortality in areas where mortality rates due to trapping/hunting had been identified as a serious risk to marten populations. The third measure provides additional assurance of maintaining connections between habitat blocks throughout the Tongass. It required an analysis of the effectiveness of features such as small reserves, beach fringe and riparian buffers in providing for connection between old-growth blocks in medium and large reserves and other natural setting LUDs. Where these measures do not provide for full connectivity, additional habitat was to be allocated to provide for connectivity of old-growth habitats.

With all measures in place, 1997 Alternative 11 was modified to provide for a network of large and medium-sized HCAs, capable of supporting 25 and 5 female marten each, respectively. Connection between HCAs was provided by protected habitats in riparian and beach fringes, small HCAs, and additional old-growth habitat designated for connectivity where these protected habitats were not adequate. Connections through the riparian and beach fringe were believed to be effective for marten based on studies that have shown preferential use by marten of riparian zones (Buskirk et al. 1989, Raphael and Jones (1997), Spencer and Zielinski 1983). The matrix between the reserves also contained significant, although fragmented, old-growth habitat. An average of 57 percent of the pre-1954 POG was estimated to remain unharvested in the matrix areas through the planning horizon of 100 years. The percent of old growth remaining in the matrix varies by province, but in those provinces considered at highest risk the additional habitat measures described above were to be applied in the matrix. In addition to all of the above habitat measures, road access was to be managed to reduce marten mortality where mortality had been identified as a significant risk.

Full implementation of the above strategy was believed to increase the likelihood of maintaining habitat that would support well-distributed marten populations. While there would likely be gaps in this distribution, it was estimated that there was low likelihood that there would be significant isolation among marten populations resulting from implementation of 1997 Alternative 11.

3.3.3. Alexander Archipelago Wolf

3.3.3.1. General Observations on the Wolf Panels

Important assessment factors for wolves were deer habitat capability, wolf mortality, and wolf dispersal capabilities; genetic information indicating the existence of the Alexander Archipelago subspecies was new at the time of the panel assessments and was also considered, though not as a major factor. Deer habitat capability was ranked as the most important factor influencing panel evaluators' ratings because of the close link between wolf persistence and deer habitat capability (Iverson 1996c, 1997c). Thus, alternatives that contributed to greater deer habitat capability, as determined by the deer habitat capability model (see *Wildlife* section of Chapter 3 for a description), and thus greater numbers of deer, were ranked as more likely to sustain viable and well-distributed wolf populations. Deer habitat capability can be reduced directly by timber harvest, which may increase deer vulnerability to predators, especially in winters of heavy snowfall.

Roads were a primary factor associated with wolf mortality identified by the panels; however, the panels agreed that the main issues were related to human access and attitudes (i.e., issues of season and bag limits, proper access management, and human education), rather than the miles of road or road densities proposed by the alternatives. It was recognized that increased road densities contributed to increased legal and illegal mortality. Thus, the value of maintaining roadless refugia was identified as a means of providing deer habitat capability and controlling human access, and alternatives that maintained such areas were ranked as more likely to sustain viable and well-distributed wolf populations.

Wolf population distribution and the interaction of populations with respect to gaps was also an issue discussed by the panel, given the dispersal capabilities of wolves. A gap in wolf distribution was defined as approximately 100 square miles between populations, or the estimated size of a wolf pack territory on Prince of Wales Island. The most current genetic information available at the time suggested that interchange among wolf populations was occurring across major island groups in Southeast Alaska. However, there was disagreement on this point between local experts and evaluators since direct ecological evidence suggested the existence of dispersal barriers or at least severe limitations to such dispersal, especially between Prince of Wales Island and neighboring islands and the mainland, as demonstrated by available radio-telemetry data (Iverson 1996c). The panel did highlight the potential ecological concerns associated with insular populations of wolves.

3.3.3.2. Wolf Panel Results

The final average panel ratings for Alexander Archipelago wolf are displayed in Table D-11. For all 1997 alternatives, it was concluded that there was virtually no chance of extirpation of the wolf from the Tongass National Forest (Outcome V). All alternatives had only 1 of a possible 100 points assigned to this outcome, with the exception of Alternatives 9 and 9' in the 1997 panel, which had 3 points assigned. This likely represents a chance catastrophic event that, in combination with normal Forest Service activity, would result in the complete extirpation of wolves.

Alternative 1 (1997) provided the greatest relative likelihood of maintaining stable well distributed wolf populations across their current range on the Tongass. However, panelists indicated that even with no action, past management activity that reduced deer habitat capability on some portions of the forest (north and central Prince of Wales Island were specifically identified) would at least result in some likelihood of locally reduced population levels (the sums of Outcomes II, III, and IV were 12 – 19, depending on the panel). Outcome II for Alternative 1 was explained as the likely result of natural fluctuations in wolf populations in response to prey availability and other environmental factors.

[1] Mean likelihood outcome scores by evaluators in 1997 are shown at the top of the table. Scores from the 1995 panel are shown in the middle of the table. Scores were assigned by both panels for Alternatives 1, 2, 5, and 9'. Alternatives 1 and 9' are identical between panels in both features and acres of POG harvested. Alternatives 2 and 5 are identical in features but with fewer acres of POG harvested in 1997 relative to 1995. A range for all alternatives is shown at the bottom of the table for the likelihood of maintaining habitat to support viable and well distributed goshawk populations. Only 'after' scores are shown. The - 414,000 value for POG harvest under Historic represents the acreage harvested since 1954.

Because of the intensity of proposed harvest activity and anticipated significant regional reductions in deer habitat capability, Alternatives 2, 7 and 9 were rated by the 1995 panel to have some likelihood (range 9-19) of creating populations that would exist in refugia with severely restricted interaction between them (Outcome IV) (Iverson 1996c); the points for this outcome were dropped considerably by the 1997 panel, ranging from 3 to 6 for Alternatives 2, 9, and 9' (Iverson 1997c).

The likelihood of an alternative resulting in a situation in 100 years where either gaps in distribution occur, populations exist in refugia, or total extirpation may be a general indication that wolf populations would not remain well distributed across the Tongass compared to historical distributions. This cumulative likelihood is considered the sum of Outcomes III, IV, and V. The 1995 and 1997 versions of Alternatives 7, 8, 9, and 9' all had relatively high cumulative likelihood outcomes, ranging from 50 to 71. Moderate likelihoods existed for Alternatives 2 (40) and 6 (36). These cumulative outcomes are generally directly related to the total harvest levels and associated reductions in deer habitat capability and all have in common a 100-year timber harvest rotation timber management regime.

Overall, the results of the 1995 and 1997 evaluations were consistent. Of those alternatives reviewed in both 1995 and 1997, Alternatives 1, 5, 2, and 9' were ranked in order from least to highest risk to wolf habitat in both assessments (Table D-11). In the 1997 evaluation, Alternatives 11, 10, and 5 were all given relatively high ratings, and these were similar to ratings given to Alternative 3 in 1995. These results are consistent with the discussion of alternatives in Chapter 3 of the 1997 FEIS, except that the analysis in Chapter 3 clearly distinguished Alternative 11 as the most favorable for wolves among the alternatives that propose to continue timber harvest, primarily due to the more extensive reserve system in Alternative 11.

3.3.4. Brown Bear

3.3.4.1. General Observations on the Brown Bear Panels

Important assessment factors identified by the brown bear panel included acres harvested, roads and access management, large reserves and legislated conservation areas, and riparian habitat management. Alternatives that harvested more acres were given a lower likelihood of maintaining habitat sufficient to support a viable and well distributed brown bear population. The driving force behind this relationship were the cumulative effects of timber harvest (i.e., the combination of clearcuts, road construction, and risks to salmon populations on bears), though direct effects, such as the temporary displacement of bears due to their tendency to avoid recently clearcut areas, were also taken into account (Iverson 1996d, Meade 1997). Likewise, alternatives that did not include effective access management or proposed a greater number or road miles were rated as having a lower likelihood of supporting viable and well-distributed brown bear populations. This was related to the potential for direct effects such as the increased potential for brown bear mortality due to legal hunting, illegal killing, and defense of life and property, as well as the creation of either temporary or permanent gaps in the distribution of the brown bear population. Indirect effects associated with the extent of proposed road construction related to the risks posed to anadromous salmon, the primary food source of brown bears (the panels relied on the 1996 fish and riparian panel results to assess this).

Large OGRs and legislated conservation areas where timber harvest is not permitted were considered a critical factor in the rating of these alternatives due to their function in providing roadless refugia for brown bears. Thus, alternative that allocated a greater number of acres to these reserves were rated as having a higher likelihood of supporting viable and well-distributed brown bear populations. The spatial distribution of these areas was also taken into account, as was the likelihood that they would persist in a roadless state over time.

Two aspects of riparian habitat management were identified as being important to brown bears: the maintenance of riparian habitat capable of sustaining salmon habitat and populations over time and providing sufficient forest cover to maintain important brown bear feeding and loafing areas. Alternatives that provided greater protection to riparian areas were considered more likely to provide adequate travel corridors to foraging areas, loafing areas, and vegetative cover capable of reducing adverse encounters among brown bears (i.e., sows with cubs) and between bears and humans.

3.3.4.2. Brown Bear Panel Results

Average panel ratings are shown in Table D-12. Panelists unanimously agreed that brown bears were not likely to be extirpated in 100 years from the Tongass National Forest under any alternative. All panelists rated Outcome V as 0 for all alternatives; wilderness and LUD II (legislated) areas essentially assured brown bear persistence somewhere in Southeast Alaska in 100 years. Alternative 1 was rated highest in total likelihood of maintaining brown bears in their current distribution, with combined scores of Outcomes I and II of 93, although certain populations would experience some reduction in overall density (a 76 score for Outcome II). The likelihood rating of 6 for Outcome III was due to the extent of past roading and an anticipated future growth in human use of existing roads, in spite of little or no additional timber harvest.

Due to the planned extensive timber harvest and associated road construction, Alternatives 7 and 9' had the highest likelihoods of limiting distribution of brown bears such that they might exist only in isolated refugia, with Outcome IV scores of 40 and 25-41, respectively.

Panelists generally agreed that either Outcomes III, IV, or V would not represent well distributed populations based upon the assessment criteria they were provided. Alternatives 2, 7, 8, 9, and 9' all had scores over 50 for Outcomes III, IV, and V combined. All of these alternatives had in common relatively extensive planned timber harvest and all were managed with a 100-year rotation. The panelists believed that these five alternatives presented the greatest relative long-term risk to the maintenance of well distributed brown bear populations in 100 years.

Alternative 3 ratings did not appear to reflect the panelists' conclusion that riparian habitat protection was a significant feature in brown bear management. Alternative 3 hds the widest riparian buffers on most channel types, yet was rated similarly to Alternatives 4, 5, 6, 10, and 11 with combined Outcome I and II scores of 60, 55, 65-67, 51, 56, and 68, respectively. The extended rotations in Alternatives 4 and 5 inferred greater dispersion of future timber harvest into roadless watersheds and were rated similar to Alternatives 3 and 6 in spite of much less total planned harvest of old growth. Alternative 11 had the highest likelihood of maintaining viable long-term brown bear populations due the extensive reserve system that should significantly address the road issue that is adverse to bears. It also has strong riparian protection. Nonetheless, all these alternatives had a reasonable likelihood of maintaining brown bear populations at least in their current distribution in spite of the potential for development of temporary gaps in distribution.

Subpopulations in Southeast Alaska were rated separately. Panelists generally had greater concerns for the mainland bear populations than the populations on Chichagof/Baranof and Admiralty Islands. The mainland population was rated consistently lower than Chichagof/Baranof for all alternatives in combined Outcomes I and II. These ratings supported discussion that focused significant concern on the low density population that may already exist in relatively isolated regions. Anticipated future roading and human access development would exacerbate this natural situation and place these populations at additional risk.

Overall, the results of the 1995 and 1997 evaluations were consistent. Of those alternatives reviewed in both 1995 and 1997, Alternatives 1, 5, 2, and 9 were ranked in order from least to highest risk to brown bear habitat in both assessments (Table D-12). However, the panel results suggested that Alternatives 5 and 11 would produce similar outcomes for brown bears, while analysis based on the components of the alternatives (Chapter 3 of the 1997 FEIS) indicated that Alternative 11 was more effective than Alternative 5 in reducing risk to bears. Alternative 11 has a much greater reserve system than Alternative 5, including additional large reserves on Northeast Chichagof Island in a landscape that was identified as high risk by the 1995 panels. In addition, Alternative 11 provides more substantial riparian protection than Alternative 5, and this feature was identified as important for bears.

[1] Mean likelihood outcome scores by evaluators in 1997 are shown at the top of the table. Scores from the 1995 panel are shown in the middle of the table. Scores were assigned by both panels for Alternatives 1, 2, 5, and 9'. Alternatives 1 and 9' are identical between panels in both features and acres of POG harvested. Alternatives 2 and 5 are identical in features but with fewer acres of POG harvested in 1997 relative to 1995. A range for all alternatives is shown at the bottom of the table for the likelihood of maintaining habitat to support viable and well distributed goshawk populations. Only 'after' scores are shown. The -414,000 value for POG harvest under Historic represents the acreage harvested since 1954.

3.3.5. Other Terrestrial Mammals

3.3.5.1. General Observations on the Other Terrestrial Mammals Panels

This panel identified two groups of mammals associated with POG for evaluation: widely distributed taxa (widely distributed group), and endemic taxa (endemic group).

Widely distributed group included:

- black bear (Ursus americanus)
- Canada lynx (Lynx canadensis canadensis)
- wolverine (Gulo gulo luscus)
- fisher (Martes pennanti)
- northern flying squirrel (Glaucomys sabrinus zaphaeus)
- river otter (Lutra canadensis mira)
- mountain goat (Oreamnos americanus columbiae)
- silver-haired bat (Lasionycteris noctivagans)
- California Myotis (Myotis californicus caurinus)
- Keen's Myotis (Myotis keenii keenii)
- little brown Myotis (Myotis lucifugus alascensis)
- long-legged Myotis (Myotis volans longicrus).

The endemic group included:

- Prince of Wales Island flying squirrel (*Glaucomys sabrinus griseifrons*)
- beaver (Castor canadensis phaeus)
- Keen's mouse (Peromyscus keeni sitkensis)
- red-backed vole (Clethrionomys gapperi stikinensis)
- red-backed vole (Clethrionomys gapperi solus)
- red-backed vole (Clethrionomys gapperi wrangeli)
- red-backed vole (Clethrionomys gapperi phaeus)
- Admiralty Island meadow vole (Microtus pennsylvanicus admiraltiae)
- Sitka meadow vole (Microtus oeconomus sitkensis)
- ermine (Mustela erminea aiascensis)
- ermine (Mustela erminea initis)
- ermine (Mustela erminea celenda)
- Admiralty Island ermine (*Mustela erminea salva*)
- Suemez Island ermine (*Mustela erminea seclusa*)

Because multiple species were considered by the panel, likelihood scores given to the most vulnerable or sensitive taxon within a group were applied to the entire group in 1995, thus these panel ratings result in conservative scores. The 1997 panel assessment rated the species as a group due to the underlying uncertainty level for the ratings of the endemic group due to the lack of ecological knowledge for many of the species.

The panel recognized that certain endemics may yet be discovered while other endemics may be more common than originally thought. The panel identified that the greatest concern for endemic species was their restricted ranges, which naturally increased their risk of extinction, and that being an endemic species equated to increased risk. Thus the panel predicted that all of the proposed alternatives had some likelihood of causing extirpation within the endemic group and likelihood increased with higher levels of timber harvest proposed. For the endemic group, Alternative 2 was determined to have a low likelihood of maintaining viable and well-distributed populations due to the absence of a reserve network and the amount of timber harvest proposed. Alternative 6 and 11 were both determined to have a moderate likelihood of maintaining viable and well-distributed endemic mammal populations, with Alternative 11 being the best, due to proposed harvest levels and rotation length (100 versus 200 years).

3.3.5.2. Other Terrestrial Mammals Panel Results

Average panel ratings are shown in Tables D-13 and D-14. Alternative 1 was generally considered by the panels as the alternative least likely to negatively impact taxa under consideration. The panels predicted a higher likelihood that the *widely distributed group* would experience ephemeral range distribution gaps (Outcome II) in both 1995 and 1997; the *endemic group* was predicted to occur more frequently in refugia (Outcome IV) in 1995, but the 1997 panel predicted a higher likelihood for Outcome II, as for the widely distributed group. Panelists assigned these outcomes based upon historical levels of timber-related activities. The panels suggested that Alternative 1 could be improved by restoring old growth in extensively harvested areas (northern Prince of Wales Island for example).

Alternatives 5 and 11 were regarded by panelists as the second and third least likely alternatives to negatively impact taxa under consideration. The panels offered higher likelihoods that the *widely distributed group* would experience both ephemeral and permanent range distribution gaps (Outcomes II and III) that could affect viable populations well-distributed across the planning area. Little brown Myotis was cited as one animal whose local populations would be more ephemeral under this alternative; it was predicted that fisher could experience significant gaps in its historic range. The *endemic group* would more likely have range distribution gaps or be restricted to refugia under Alternatives 5 and 11 (Outcomes III and IV). These circumstances would increase the risk of extirpation as a result of isolation. Prince of Wales Island flying squirrel was noted as one animal that would likely only exist in refugia. Panelists stressed that reserves should be carefully located within the ranges of vulnerable wildlife and that corridors be truly functional.

Panelists ranked Alternatives 3, 4, 6, and 10 as intermediate among the alternatives in terms of likelihood of negatively impacting taxa under consideration. For the *widely distributed group*, likelihood scores were fairly evenly distributed among Outcomes II, III, and IV; scores for outcome extremes (I and V) were consistently lower for these alternatives. Likelihood scores were similarly distributed for the *endemic group*, except scores were higher for Outcome V, particularly for Alternatives 3 and 6 in 1995. For most of these alternatives, local populations of Sitka mouse could become more ephemeral (Outcome II); northern flying squirrel could experience permanent gaps in its historic range or exist only in refugia (Outcome III or IV); fisher could exist only in refugia (Outcome IV).

The panel considered Alternatives 2, 7, 8, 9, and 9’ to be most likely among alternatives to create wildlife viability problems. The panel predicted that implementation of these alternatives would result in high likelihoods that both the *widely distributed and endemic groups* would exist only in refugia (northern flying squirrel for example) or would become extirpated (Keen’s Myotis for example). It was suggested that these alternatives could be improved by incorporating longer rotations, uneven-aged management, and higher levels of riparian habitat protection.

For the widely distributed group, it was determined that Alternative 2 had a very high likelihood of resulting in conditions of either refugia or extirpation in 100 years (not viable; combining Outcomes IV and V). Conversely Alternative 11 was rated as having a relatively high likelihood of not resulting in conditions of refugia or extirpation in 100 years because of its forest-wide reserve system. Alternative 6 was rated as being in between Alternatives 2 and 11 (Table D-13).

There was general consistency in the 1995 and 1997 evaluations of other terrestrial mammals, although there was variation in the ratings assigned to alternatives by the two panels. Of those alternatives

[1] Mean likelihood outcome scores by evaluators in 1997 are shown at the top of the table. Scores from the 1995 panel are shown in the middle of the table. Scores were assigned by both panels for Alternatives 1, 2, 5, and 9'. Alternatives 1 and 9' are identical between panels in both features and acres of POG harvested. Alternatives 2 and 5 are identical in features but with fewer acres of POG harvested in 1997 relative to 1995. A range for all alternatives is shown at the bottom of the table for the likelihood of maintaining habitat to support viable and well distributed goshawk populations. Only 'after' scores are shown. The - 414,000 value for POG harvest under Historic represents the acreage harvested since 1954.

reviewed in both 1995 and 1997, Alternatives 1, 5, 2, and 9' were ranked in order from least to highest risk to habitat of the widely-distributed group in both assessments (Table D-13). Differences between Alternatives 2 and 9' were slight in both assessments. Additionally, ratings of all these alternatives improved substantially from the 1995 to the 1997 assessment. The same pattern held true for the

endemic mammal group (Table D-14). Relative rankings of the four alternatives reviewed by both panels remained constant, but the ratings for each of the alternatives improved from the first to the second panel. These results also generally support the conclusion drawn in Chapter 3 of the 1997 FEIS that, of the alternatives that propose to continue harvesting timber, Alternative 11 poses the least risk to these species groups. However, the difference for these species between Alternative 11, as evaluated by the panelists, and Alternative 5 is small. Subsequent to the assessment by the panelists, additional measures were added to Alternative 11 to benefit these species groups.

3.3.5.3. Effects of Added Habitat Management Measures

As noted above, the other terrestrial mammals associated with POG were broadly divided into two groups: widely-distributed species and endemic species. A total of 26 taxa within these two groups were explicitly considered by the panels asked to provide judgments for the other terrestrial mammals. Two of these 26 taxa, northern flying squirrel and river otter, were the focus of specific measures in the original VPOP strategy. Small HCAs were adopted by the VPOP committee to provide for distribution of northern flying squirrels in every major watershed (i.e., every 10,000 acres). The size of these HCAs was intended to allow them to support 20 to 40 squirrels. VPOP also recommended that travel corridors be maintained between patches of flying squirrel habitat. They considered beach fringe and riparian zone to be suitable corridors, and recommended that additional corridors be designated in areas where these did not provide adequate connectivity.

The Prince of Wales river otter is strongly associated with saltwater beach fringe and freshwater riparian habitats (Larsen 1983, Noll 1988, Woolington 1984). VPOP's conservation recommendation for river otter was maintenance of beach fringe, estuary fringe, and riparian habitat associated with streams and lakes.

The review of Kiester and Eckhardt (1994) provided little comment on this aspect of the VPOP strategy. However, one of the common themes of many of the reviews was the lack of knowledge of all the taxa present on the Tongass and the distribution of species among islands. Kiester and Eckhardt (1994) recommended a thorough biological survey of the Tongass, and an evolutionary analysis of small mammals. Lidicker (in Kiester and Eckhardt 1994) recommended that no timber harvest take place on islands less than 1,000 acres or those that could be considered unique because of their isolation or known presence of endemics.

In the 1995 evaluation, the VPOP strategy, most fully embodied in Alternative 3, was assessed as having the third highest likelihood, for those alternatives that propose continuing timber harvest, of maintaining both the widely-distributed and the endemic groups of mammals. In this assessment, substantial likelihoods of not maintaining species well-distributed were projected for all alternatives, including Alternative 1 which called for no further timber harvest. These results were based, at least in part, on effects of past harvest, lack of knowledge of many of the mammal species, and risks inherent to endemic species. Alternative 11, as evaluated in the 1997 panel assessments, differed in several important ways from Alternative 3. It eliminated all islands less than 1,000 acres from the timber base as recommended by Lidicker (in Kiester and Eckhardt 1994). It extended the beach fringe to 1,000 feet, but also relied more heavily on short-rotation clearcutting than did Alternative 3. Of the alternatives evaluated in 1997 that propose continued timber harvest, it ranked second highest in likelihood of maintaining viable populations of the widely-distributed and endemic mammals. Despite its favorable ranking relative to the other alternatives, it still was projected to have substantial likelihood of not maintaining well-distributed populations. Alternative components that were viewed favorably by this panel included the presence of a reserve system, the amount of old growth that would be retained in the matrix, and a process for site-specific analysis particularly related to endemic mammals.

In response to the 1997 panel assessment, additional guidelines were added to Alternative 11 to increase the likelihood that viable populations of endemic mammals would be maintained. These guidelines require that surveys for endemic mammals be completed prior to projects that would substantially alter vegetation on islands of 50,000 acres or less. Surveys were also to be conducted on larger islands if an initial assessment indicates high likelihood that endemic mammals are present on the site. Where endemic taxa are detected by the surveys, projects were to be designed to provide for continued persistence of the taxa. As an additional measure, ongoing research of endemic taxa on the Tongass was to be accelerated.

Other guidelines added to Alternative 11 in response to the panel assessments also benefited both the endemic and widely-distributed mammals. The connectivity guideline provided additional measures to maintain connectivity of large and small reserves and other non-development LUDs in places where beach fringe and riparian habitat management areas do not provide adequate connectivity. Guidelines for structural retention for goshawk and marten habitat also benefited other mammal species.

The Prince of Wales flying squirrel may be considered the greatest viability concern among the endemic mammals that were specifically considered by the panels, and the northern flying squirrel may be of greatest concern among the widely-distributed mammals. According to Carey (1991), habitat factors important to northern flying squirrels include large, live trees; large snags; fallen trees; multilayered canopies; and connectedness of habitat either through large contiguous areas of habitat or through corridors of suitable habitat. Alternative 11 provided these features through its system of large and medium HCAs interconnected with small reserves and matrix habitats. Each large HCA should have the capability to support 100 or more northern flying squirrels, medium HCAs to support more than 50 squirrels, and small HCAs to support 20 to 40 squirrels. These individual populations should have the capability to persist over short to intermediate periods of time. Interactions among these populations through the matrix would allow them to function as a metapopulation conferring high probability of long-term persistence. Dispersal through the matrix was facilitated by the beach fringe and riparian habitat management areas, by the overall amount of old forest remaining in the matrix, and by additional measures prescribed under Alternative 11 to provide for connectivity. These additional measures could include relocating small reserves to better serve a role as connectors, thus providing for small squirrel populations at locations intermediate between the larger populations.

These same components of Alternative 11 also reduced risks to the endemic species and the Prince of Wales flying squirrel. In addition, the 200,000-acre reserve designated on Prince of Wales Island, by itself, was expected to support a moderately large population of squirrels. Another feature of Alternative 11 that was to further reduce risk to Prince of Wales flying squirrels was the requirement to survey for endemic mammals on islands of 50,000 acres or less, or in other areas where there is a high likelihood of species presence. Application of this measure to Prince of Wales Island was expected to result in additional project-specific measures reducing risk to the squirrels. Finally, implementation of mitigation measures for goshawk and marten on Prince of Wales Island was expected to result in the retention of structural features important to flying squirrels such as snags, logs, and large live trees.

Implementation of the survey requirement was expected to substantially reduce risks to other endemic species. This requirement, in combination with the ongoing research on endemic taxa, is responsive to Kiester and Eckhardt's (1994) recommendation to conduct a biological survey on the Tongass.

3.3.6. Marbled Murrelet

3.3.6.1. General Observations on the Marbled Murrelet Panel

Only one panel was conducted for the marbled murrelet (Smith 1996). The panel noted the lack of distributional and ecological information about marbled murrelets, especially in Southeast Alaska. They appeared to make the following general assumptions about harvest practices and other components of the alternatives relative to marbled murrelets and in particular to nesting habitat.

1. The best or most important habitat is found within large contiguous blocks of high-volume, low-elevation old-growth forest. In Yakutat and Glacier Bay this may include stands of large mature Sitka spruce.

2. The main concern with fragmenting or reducing such habitat is an increase in predation rates (more edge and less interior).
3. Canopy cover above the nest (highest in the high-volume stands) is another critical factor in keeping predation rates lower.
4. The maintenance of old-growth forest reserves, and extended rotations, are both seen as ways to retain suitable nesting habitat. Large reserves, and rotations greater than 200 years, are favored; an alternative that would provide both Forest-wide would be ideal (assuming timber harvesting is to continue). Rotations averaging 100 years are not long enough to provide suitable habitat.
5. Riparian and beach fringe old growth, due to its linear nature (more edge, less interior), is considered less suitable nesting habitat than interior old growth. Alternatives with higher amounts of riparian and beach fringe protection may work against murrelets by pushing harvest into critical nesting habitat. Conversely, higher riparian protection could lead to improved habitats overall through a synergistic effect resulting from more interconnectivity.
6. The retention of spatially-explicit small OGRs (as in the one/watershed in Alternatives 3) is favored over the "33 percent residual" concept of Alternatives 5 and 6.

3.3.6.2. Marbled Murrelet Panel Results

Average panel ratings are shown in Table D-15. Based on these ratings, the nine alternatives rated fell roughly into four groups. Alternative 1 was by itself with all of its outcome points assigned to Outcomes I or II. The very low level of timber harvest, all of it under a 200-year rotation, resulted in a rating considerably higher (in terms of ensuring viability) than the other alternatives. The assignment of points to Outcome II was primarily a result of the amount of low-elevation, high-volume old growth already harvested.

Alternatives 3, 4 and 5 all rated fairly high, with at least 74 percent of the points in Outcomes I or II. Alternative 5, offering extended rotations and reserves in critical areas, had the highest viability scores of this group, although the panel would have preferred spatially-identified small reserves rather than the 33 percent residual old growth concept. The full reserve system and greater riparian protection, combined with two-aged management, of Alternative 3 was favored somewhat over the Forest-wide uneven-aged management, but no reserves, of Alternative 4.

Alternatives 2, 6, and 9 each had most of their points (67-74 percent) assigned to Outcomes II or III, and except for Alternative 9 have over 90 percent in Outcomes I-III, providing moderate to high viability ratings (although not all panelists felt Outcome III would meet viability requirements). The rationale for these scores varied by alternative. Alternatives 6 rated highest of this group due largely to their reserve systems, two-aged rather than even-aged timber harvesting, and watershed-specific residual old growth requirements. The 100-year rotations in each were a drawback. Alternatives 2 and 9 rated somewhat lower than Alternatives 6, neither of the former having a reserve system and both using even-aged harvest with 100-year rotations.

Finally, Alternative 7, similar to Alternatives 2 and 9 and with a higher timber harvest level, had the lowest viability rating, assigning 2/3 of its points to Outcomes III or IV.

[1] Mean likelihood outcome scores by evaluators in 1997 are shown at the top of the table. Scores from the 1995 panel are shown in the middle of the table. Scores were assigned by both panels for Alternatives 1, 2, 5, and 9'. Alternatives 1 and 9' are identical between panels in both features and acres of POG harvested. Alternatives 2 and 5 are identical in features but with fewer acres of POG harvested in 1997 relative to 1995. A range for all alternatives is shown at the bottom of the table for the likelihood of maintaining habitat to support viable and well distributed goshawk populations. Only 'after' scores are shown. The - 414,000 value for POG harvest under Historic represents the acreage harvested since 1954.

Marbled murrelet likelihood outcome ratings were also highly correlated (0.98) with acres of POG planned for harvest over a 100 year rotation. Alternative 10 was very similar in design to Alternative 3, but did not have the extended beach nor option 1 and 2 riparian buffers, both features considered important by panelists, thus presented greater relative risks than Alternative 3. The system of large and medium and unmapped small old-growth habitat reserves in Alternative 10 was also an important feature, thus superior in design with lower relative risk that Alternative 2.

Alternative 11 harvested almost the lowest amount of old growth (Table D-15), had the most extensive forest-wide reserve system with very large reserves in heavily harvested provinces, and had an extended beach and significant riparian protection. The only possible drawback of Alternative 11 was the 100-year timber harvest rotation in the matrix, viewed as unfavorable by panelists. However, an average of nearly 57 percent of the original 1954 POG would remain in all watersheds under timber management contributing to a diversity of stands and habitat mosaics, clearly superior to extensive even-aged stands. Thus, Alternatives 1 and 11 were believed likely offer the highest likelihood of maintaining well distributed viable murrelet populations.

Commentary on the Panel Ratings. The marbled murrelet is second only to the Other Terrestrial Mammals panel with respect to the lack of local information available to assess long-term viability. Viability concerns for the marbled murrelet in southeast Alaska intensified due to listing of this species as threatened under ESA in California, Oregon, and Washington and the very close habitat affinity with coastal old growth forests (Ralph et al. 1995). Information to substantiate this concern in southeast Alaska is only indirect relative to the loss of nearly one million acres of POG coastal temperate rainforests throughout southeast Alaska (including all ownerships). These are generally the more productive sites at low elevation, presumably some of the best murrelet nesting habitat (DeGange 1996). However the strength of the association between murrelet nesting habitat and highly POG forest has not been established; indeed two of the six nests located in Southeast Alaska to date have been on the ground.

Short term (10-15 years) risks to murrelet viability are difficult to assess but are likely minor especially given the magnitude of recent conservative population estimates of over 365,000 marbled murrelets in southeast Alaska (DeGange 1996). Further, murrelets appear to be highly mobile traveling up to 50-60 miles per day on foraging flights (DeGange 1996) suggesting at least the possibility of relatively high population interaction throughout southeast Alaska. Short term risks are likely proportional to the amount of additional old growth planned for harvest among alternatives (1, 11, 5, 4, 3, 10, 6, 2, 9 and 7 in order of increasing risk) within the planning period covered by the Forest Plan Revision. While large block reserves in general may be a preferable conservation strategy, the small (1,600 acre) block reserves (Alternatives 3, 10, 11 and parts of 5 and 6) in each watershed may significantly contribute to maintenance of nesting habitat and well distributed populations in the absence of additional information on nesting habitat relationships. Forest-wide Standards and Guidelines protect nesting habitat around any identified murrelet nests. However, only six murrelet nests have been found so this standard is not considered as a viable conservation strategy in itself. Rather it serves to protect habitat surrounding the few nests that may be located for long term monitoring and studies to understand murrelet habitat relationships.

Under the assumption that POG habitat is the preferred murrelet nesting habitat, then the loss of an additional 1.5 million acres in some alternatives, in addition to the million acres already lost, could contribute to a long-term viability concern. This concern may become greater if future research reveals a significant murrelet selection for high volume low elevation forests that are sought for timber production, similar to the situation documented in the Pacific Northwest (Ralph et al. 1995). DeGange (1996) suggested that long rotations may be beneficial components to a murrelet conservation strategy, he concluded that a reserve system was more likely to present a viable conservation strategy for murrelets given significant unknowns about this elusive specie; protecting intact landscapes/ecosystems is a better hedge against uncertainty.

The significant reserve system in Alternative 11, especially in at-risk landscapes with significant past timber harvest (reserves partially discussed under Wolf) may make this alternative superior to all others (except Alternative 1). The reserve system in additional to significant matrix protection should provide a reasonably high likelihood of sustaining well-distributed viable murrelet populations throughout southeast Alaska.

Even over long time periods, there is less relative concern for the marbled murrelet compared to other old growth associated vertebrates assessed by panels. Average murrelet scores for Outcome I and II rated higher than all other species in all alternatives except for the wolf in Alternatives 2 and 3.

3.4. New Science Relevant to Wildlife Viability Assessment Since 1997

The process of assessing wildlife risk through a structured panel assessment process is one of a variety of methods for conducting a viability assessment. Beissinger and McCullough (2002) compiled a reference which consists of a set of review papers on population viability analysis. This section presents a summary of the science that is relevant to wildlife viability assessment since 1997. It is largely based on a review of recent science relative to population and species viability assessment conducted by Haufler (2006).

Numerous factors influence the viability of any species. However, habitat is the greatest overall factor affecting viability of a species (Wilcove et al. 1998). Reed et al. (2006) identified four broad classes of factors influencing viability of a species; population size and structure, habitat, demography, and relationships between demographic rates and habitat and between demographic rates and population size. In addition, many other minor factors can play a role. Given this myriad of potential influences on the viability of a species, it is not surprising that quantification of species viability has been a difficult task. Consequently, most assessments of species viability in a planning or impact assessment context have been conducted qualitatively, usually with the use of expert opinion in relation to projected future conditions.

Species viability assessment based on habitat has ranged from expert assessments of future population status based on projected habitat conditions to more complex analyses of individual home ranges and their contributions to species persistence in spatially-explicit individually-based population viability models (Noon et al. 1999). Individually-based spatially explicit models may be the most realistic (Breininger et al. 2002), but these approaches also require many model parameters that may not be known with any accuracy, and include various assumptions that may be difficult to test. The spatial description of habitat quality produced from this approach can be used for a variety of habitat-based population viability assessments (Akcakaya and Atwood 1997, Akcakaya 2000). Lawler and Schumaker (2004) evaluated habitat surrogates for population parameters of red-shouldered hawks and goshawks, and found poor relationships between predicted habitat quality and observed habitat quality.

Various models for population viability assessment (PVA) have been proposed and developed (see review by Akcakaya and Sjogren-Gulve 2000), most involving theoretical relationships of demographic data. The idea behind PVA has been to determine an estimate of the extinction risk to a species based on current demographic conditions and alternative future conditions. Given the complexities of species viability described above, it is not surprising that sufficient data generally do not exist to conduct a thorough population viability analysis. For example, Green and Hirons (1991) reported that data suitable for population modeling were available for only 2 percent of threatened bird species, taxa about which we know the greatest amount, while Samson (2002) reported that suitable data existed to conduct a PVA for only 3 of 119 species at risk in the Northern Great Plains. Beissinger and Westphall (1998) discussed use of PVAs in endangered species management. They suggested caution in use of predictions produced from such analyses because of the unreliability of data available for such models as well as the lack of understanding of both periodic fluctuations and density dependent factors, and varying model assumptions that can cause changes in results. They suggested that PVAs consider relative rather than absolute rates of extinction, be limited to short projections, and use models compatible with the available data.

A number of different demographic-based approaches have been proposed for assessing species viability. As with habitat-based approaches, these range from relatively simple approaches to much more complex approaches (Haufler 2006). Incidence function models are relatively simple models designed to provide an estimate of the risk of extinction (Hanski 1999). This approach requires the presence or absence of species of interest to be determined for various habitat patches in a landscape over a time. Appropriate time frames are difficult to estimate, as different populations have different generation times and vulnerability to extinction events. This approach assumes relatively static habitat conditions (Ralls et al. 2002), an unlikely condition for management planning or impact assessments.

A second demographic-based approach is the use of population trend information (Morris et al. 1999). This approach requires the population of a species to be consistently monitored over time to determine any changes in the population size. Morris et al. (1999) recommended a minimum of 7 years of trend data for accurate analysis. Even with this information, the population trend applies only to that time interval and landscape studied.

A number of population simulation models have been developed that address questions of productivity and survival rates of a population (Haufler 2006). These models require detailed information on the demographics of the population under evaluation, data that are seldom available (Bessinger and Westphal 1998).

Certain populations may be limited by the spatial distribution of their habitat, where dispersal among patches is a relatively rare event, so that population demographics within a patch are largely independent of other habitat patches within the landscape. When this arrangement occurs, it is known as a metapopulation (McCullough 1996, Hanski and Gilpin 1997). A number of metapopulation models have been developed that attempt to address population persistence in patches as balanced by dispersal rates among patches. Such models, to be accurate, require information on the status of a population within a habitat patch, including the habitat quality, population size, and internal-patch demographic parameters. In addition, the distribution, and size of other patches in the landscape and rates of successful dispersal among the patches must be known. Dispersal data are one of the least known and most difficult parameters to assess for a population, and small errors in assessment of dispersal can cause large errors in projections of metapopulation models (Reed et al. 2002). In addition, even if these population parameters are collected, as with other demographic parameters, they are usually not transferable to other conditions than those in which they were collected.

Concerns over habitat fragmentation have led many to assume that populations are regularly being converted to metapopulations, and to view any system with a patchy distribution as a metapopulation (Hanski and Simberloff 1997, Harrison and Taylor 1997). However, this is generally not correct, as actual metapopulations are rare (Harrison and Taylor 1997). Hanski (1999) discussed the basic parameters that need to be considered to conduct a metapopulation analysis.

Smith and Zollner (2005) argue that using the most vulnerable species, or evaluating single species without reference to others, to assess impacts of land management likely underestimates the probability of extinction of wildlife species across the planning area because the risk of local extirpation increases with the number of extinction prone species considered. Additionally, the management alternative that poses the greatest risk to the most vulnerable wildlife species may not pose the greatest risk to the wildlife community as a whole (Smith and Zollner 2005). The authors present an alternative method for assessing risk to wildlife viability that considers the risk of "any" extinction among species at risk in the planning area. To accomplish this, an equation is used which calculates the joint probability of at least one extinction among the set of selected species (derived from panel assessment ratings or population viability analysis), which can then be used to conduct a relative comparison of alternatives. That is, it takes into account the marginal, or individual, extinction probability of each species. This approach is used here as an alternate method for comparing the effects of the alternatives on wildlife viability (see Section 3.6 and the *Wildlife* section of Chapter 3 for further discussion).

Global climate change has been a subject of increasing interest and focus in the past 10 years. A number of publications have discussed biodiversity conservation in the face of global warming. Saxon (2003) presented a good discussion of this topic. He recommended that conservation planning occur across ecoregions, and that these ecoregions be identified based on abiotic factors including climate, but also based on other abiotic factors than climate as this factor is likely to change. With climate change expected to have a greater effect on more polar regions, incorporating the potential consequences of global warming relative to conservation planning in Alaska is warranted.

3.5. Application of Panel Assessments to the 2008 FEIS Alternatives

The 1997 Forest Plan Revision Final EIS wildlife analysis relied in part on the expert panel evaluations of alternatives in terms of the estimated relative risks to a species or habitat of concern, as described in Sections 3.2 and 3.3. The 2008 Forest Plan Amendment FEIS also relies in part on these panel evaluations. Of the seven alternatives analyzed in the 2008 FEIS, four of them are very similar to or based on alternatives analyzed during the panel assessments. In addition, the harvest levels of all 2008 alternatives are within the range of the 1997 alternative harvest levels, given that a no-harvest alternative was analyzed in 1997. As described in Section 3.1, there was a strong correlation between the acres of POG scheduled for harvest in an alternative and the mean outcome scores for that alternative resulting from the panel assessments (Section 3.3). As the number of acres harvested increased among alternatives, the mean outcome scores also increased, resulting in greater risk that habitat may not be sufficient to maintain viable and well distributed populations. Therefore, the panel evaluations can be used to make inferences about the 2008 alternatives.

The accuracy of this approach was tested in 1997 (Section 3.1). The 1997 FEIS, which was developed prior to the 1997 panel assessments, evaluated two alternatives, which had not been assessed by the panels, by making inferences based on harvest acres; these inferences and the resulting alternative evaluations were generally confirmed based on the 1997 panel assessments (see Appendix N to the 1997 FEIS).

The relationship between the 2008 alternatives and the 1997 alternatives in terms of equivalency of features, land base, and acreage of POG potentially harvested is summarized in Table D-16, for use in rating the 2008 alternatives in terms of the panel assessments.

Based on the equivalencies given in Table D-16 and supplemental information, viability ratings for the 2008 alternatives were developed and are summarized in Table D-17. The ratings were based on the midpoint of the range between the sum of Outcomes I+II and the sum of Outcomes I+II+III for each alternative. The midpoint of the range between these sums was used as the index of viability because viability was generally assumed by panelists to lie between the sum of Outcomes I+II and the sum of Outcomes I+II+III (USDA Forest Service 1997(Appendix N, p.N-3). The 2008 alternatives were evaluated by applying the equivalencies or rankings in Table D-17 to the panel assessment midpoint values as shown in the tables in Section 3.3. The midpoint values were then transferred to ratings using the key provided in the footnote to Table D-17. Further explanation for these ratings is provided in the following subsections.

3.5.1. Northern Goshawk

Alternatives 1, 2, and 3 in 2008 would both have midpoint values above 91, based on applying Table D-16 equivalencies and rankings to Table D-9. Therefore, they are expected to have very high viability ratings for goshawks. Alternatives 5 and 6 in 2008 are both similar to 1997 Alternative 11, which had a midpoint value of 84. In addition, 2008 Alternatives 5 and 6 both include supplemental measures, which may have a positive effect on viability; 2008 Alternative 5 includes the goshawk and marten standards and guidelines and 2008 Alternative 6 includes the legacy forest structure standards and guidelines. Neither of these measures were evaluated by either of the panels, so their value for goshawks was not considered. As a result of this and the 84 midpoint value for 1997 Alternative 11, 2008 Alternatives 5 and 6 are rated in the high category for goshawks. Alternative 4 in 2008 is rated as moderately high, because the midpoint value for 1997 Alternatives 10, 3, and 6, ranges from 66.5 to 74. Alternative 7 in 2008 is equivalent to 1997 Alternative 2, which had a midpoint value of 40.5. This value falls within the moderate range.

Table D-16.
Relationship of 2008 Alternatives to 1997 Alternatives for Use in Rating 2008 Alternatives in Terms of Panel Assessments

2008 Alternatives	Equivalency or Ranking in terms of 1997 Alternatives*
Alternative 1 84,000 acres of potential POG harvest	2008 Alternative 1 has a lower POG harvest than any of the 1997 alternatives with POG harvest. Ratings for this alternative should be between 1997 Alternative 1 with 0 harvest and 1997 Alternative 5 (with 463,000 acres of harvest) or 1997 Alternative 11 (with 475,000 acres of harvest). Based on the low POG harvest levels, ratings would be closest to (but greater than) Alternative 1.
Alternative 2 223,000 acres of potential POG harvest	2008 Alternative 2 has a lower POG harvest than any of the 1997 alternatives with POG harvest. Ratings for this alternative should be between 1997 Alternative 1 with 0 harvest and 1997 Alternative 5 (with 463,000 acres of harvest) or 1997 Alternative 11 (with 475,000 acres of harvest). Based on harvest levels, ratings would be in the middle of the range between Alternative 1 and Alternatives 5 or 11.
Alternative 3 325,000 acres of potential POG harvest	2008 Alternative 3 has a lower POG harvest than any of the 1997 alternatives with POG harvest. Ratings for this alternative should be between 1997 Alternative 1 with 0 harvest and 1997 Alternative 5 (with 463,000 acres of harvest) or 1997 Alternative 11 (with 475,000 acres of harvest). Based on harvest levels, ratings would be closer to (but less than) Alternatives 5 or 11.
Alternative 4 644,000 acres of potential POG harvest	2008 Alternative 4 is similar to 1997 Alternative 6 in terms of features and land base. The acres of POG harvest are lower for the 2008 Alternative 4 at 644,000 compared with the 1997 Alternative 6 at 732,000. However, only the 1995 version of Alternative 6 was evaluated by the viability panels, and the acres of POG harvest are considerably lower in 2008 vs. 1995 (644,000 vs. 954,000, respectively). The alternative that was reviewed by the viability panels and is the closest to the 2008 Alternative 4 is the 1997 Alternative 10 (670,000 acres of harvest). So ratings for 2008 Alternative 4 are expected to be between 1995 Alternative 6 and 1997 Alternative 10; being closer to the latter alternative.
Alternative 5 479,000 acres of potential POG harvest	2008 Alternative 5 is similar to 1997 Alternative 11 in terms of features, land base, and POG harvest (481,000 vs. 463,000 acres of harvest, respectively). Therefore, the ratings for this alternative would be similar to the ratings for 1997 Alternative 11.
Alternative 6 472,000 acres of potential POG harvest	2008 Alternative 6 is similar to 1997 Alternative 11 in terms of features, land base, and POG harvest (472,000 vs. 463,000 acres of harvest, respectively). Therefore, the ratings for this alternative would be similar to the ratings for 1997 Alternative 11.
Alternative 7 826,000 acres of potential POG harvest	2008 Alternative 7 is similar to 1997 Alternative 2 in terms of features, land base, and POG harvest (826,000 vs. 853,000 acres of harvest, respectively). Therefore, the ratings for this alternative would be similar to the ratings for 1997 Alternative 2.

* POG harvest levels in 1997 are based on values given to the panels, which were different, in some cases from the final scheduled acres given in the 1997 FEIS.

Table D-17.
Viability Ratings (likelihood of maintaining habitat to support viable and well distributed populations) assigned to the 2008 Alternatives based on the Equivalent Panel Assessment Ratings from the 1995/1997 Panel Assessments

Species	Alternatives						
	1	2	3	4	5	6	7
Goshawk	Very High	Very High	Very High	Moderately High	High	High	Moderate
Marten	Very High	High	High	Moderate	Moderate	Moderate	Moderate
Wolf	Very High	Very High	High	High	High	High	Moderately High
Brown Bear	Very High	High	High	Moderately High	High	High	Moderately High
Widely Distributed Mammals	High	Moderately High	Moderately High	Moderate	Moderate	Moderate	Moderately Low
Endemic Mammals	Moderate	Moderate	Moderate	Moderately Low	Moderate	Moderate	Very Low
Marbled Murrelet	Very High	Very High	Very High	High	Very High	Very High	Moderately High

[1] Ratings were based on the midpoint of the range between Outcomes I+II and Outcomes I+II+III for each alternative, as determined by applying the equivalencies or rankings in Table D-17 to the panel assessment results tables in Section 3.3. The midpoint values were then transferred to ratings using the following key:
Very High: 91-100, High: 81-90, Moderately High: 66-80, Moderate: 35-65, Moderately Low: 20-34, Low: 10-19, Very Low: 0-9.

In addition, these ratings may be conservatively low. Information from recent studies indicates that goshawks may make more use of second growth and other forest types than was assumed during the panel assessments (Bosakowski et al. 1999; McClaren 2003, 2004; Boyce et al. 2006, Reynolds et al. 2006). As noted in Section 3.3.1.1, the primary factor used by panelists in their ratings was the proportion of POG that would be harvested in 100 years. The panels assumed a strong selection by goshawks for POG and the avoidance of all other habitat types. In addition, the level of old-growth harvest that was envisioned by the panels over the past 10 years has not materialized. As a result, nearly the same amount of old growth still exists on the Tongass and the large quantities of older second growth are now 10 years closer to becoming useful goshawk habitat. Therefore, if the panels were repeated today, the ratings could be slightly higher.

Given these factors, the rankings of the 2008 alternatives relative to the 1997 selected alternative (Alternative 11) would be as follows: Alternatives 4 and 7 in 2008 would have lower viability ratings than 1997 Alternative 11, and 2008 Alternatives 1, 2, 3, 5, and 6 would have higher ratings. These higher ratings are because of a smaller managed land base, the addition of goshawk/marten (in the case of 2008 Alternative 5) or legacy (in the case of 2008 Alternatives 1, 2, 3, and 6) standards and guidelines, and new science about goshawk habitat use in Southeast Alaska. The slight change in the goshawk nest standard and guideline (see Section XX), is not expected to affect viability.

The same relative ratings are also expected to hold for the 1997 Forest Plan versus the 2008 alternatives (i.e., 2008 Alternatives 4 and 7 would have lower viability ratings and 2008 Alternatives 1, 2, 3, 5, and 6 would have higher viability ratings than the 1997 Forest Plan). These conclusions follow the same reasoning as given in the above paragraph for most of the alternatives. Table D-18 summarizes this reasoning.

Table D-18.
Goshawk Viability Ratings for the 2008 Alternatives Relative to the 2007 Forest Plan[1/]

Alternatives	Comparison with 2007 Forest Plan1/	Viability for Alternative relative to 2007 Forest Plan1/
Alternative 1	Acreage in protected POG is considerably higher in Alt 1 due to expanded OGRs (i.e., more acreage in Old Growth Habitat, Special Interest Areas, Semi-Remote Recreation, and other non-development LUDs). 2007 Forest Plan has goshawk S&G, marten S&G, and unmodified goshawk nest S&G, while Alt 1 has legacy S&G.	Alt. 1 has higher viability rating
Alternative 2	Acreage in protected POG is considerably higher in Alt 2 due to expanded OGRs (i.e., more acreage in Old Growth Habitat, Special Interest Areas, Semi-Remote Recreation, and other non-development LUDs). 2007 Forest Plan has goshawk S&G, marten S&G, and unmodified goshawk nest S&G, while Alt 2 has legacy S&G.	Alt. 2 has higher viability rating
Alternative 3	Acreage in protected POG is considerably higher in Alt 3 due to expanded OGRs (i.e., more acreage in Old Growth Habitat, Special Interest Areas, Semi-Remote Recreation, and other non-development LUDs). 2007 Forest Plan has goshawk S&G, marten S&G, and unmodified goshawk nest S&G, while Alt 3 has legacy S&G.	Alt. 3 has higher viability rating
Alternative 4	Acreage in protected POG is considerably lower in Alt 4 due to OGRs in only four provinces and less acreage in non-development LUDs in general. 2007 Forest Plan has goshawk S&G, marten S&G, and unmodified goshawk nest S&G, while Alt 4 does not have goshawk/marten S&Gs or legacy S&Gs.	Alt 4 has lower viability rating
Alternative 5	Same as the 2007 Forest Plan	Alt 5 has the same viability rating
Alternative 6	Acreage in protected POG is higher in Alt 6 due to expanded OGRs (i.e., more acreage in Old Growth Habitat, Special Interest Areas, and Semi-Remote Recreation). 2007 Forest Plan has goshawk S&G, marten S&G, and unmodified goshawk nest S&G, while Alt 6 has legacy S&G.	Alt. 6 has a similar viability rating
Alternative 7	Acreage in protected POG is considerably lower in Alt 7 due to OGRs in only four provinces and less acreage in non-development LUDs in general. 2007 Forest Plan has goshawk S&G, marten S&G, and unmodified goshawk nest S&G, while Alt 7 does not have goshawk/marten S&Gs or legacy S&Gs.	Alt 7 has substantially lower viability rating

1/ The 2007 Forest Plan is defined as the 1997 Forest Plan, as amended through 2007. It is represented by Alternative 5.

3.5.2. American Marten

Alternative 1 in 2008 would have a midpoint value suggesting a very high viability rating for marten, based on applying Table D-16 equivalencies and rankings to Table D-10. Based on the level of POG harvest, 2008 Alternatives 2 and 3 are expected to have a high rating. Alternatives 5 and 6 in 2008 are both similar to 1997 Alternative 11, which had a midpoint value of 64. In addition, 2008 Alternatives 5 and 6 both include supplemental measures, which were not considered in the panel assessments and these measures may have a positive effect on viability; 2008 Alternative 5 includes the goshawk and marten standards and guidelines and 2008 Alternative 6 includes the legacy forest structure standards and guidelines. As a result of this and the 64 midpoint value for 1997 Alternative 11, 2008 Alternatives 5 and 6 are rated at the upper end of the moderate category for marten. Alternative 4 in 2008 is also rated as moderate, because the midpoint value for 1997 Alternatives 10, 3, and 6, ranges from 49 to 64.5. Alternative 7 in 2008 is equivalent to 1997 Alternative 2 with a midpoint value of 51, which is also in the moderate range.

Information from recent studies indicates that the marten in Southeast Alaska may represent two species, or at least, two different genetic lineages of one species. If there are actually two species, it could indicate a greater viability concern for some islands on the Tongass (e.g., Kuiu - the endemic lineage of marten is currently only documented on Kuiu and Admiralty Islands). However, there is no information indicating that there are ecologically meaningful differences (e.g., differences in habitat use) between the two lineages.

Given these factors, the rankings of the 2008 alternatives relative to the 1997 selected alternative (Alternative 11) would be as follows: Alternatives 4 and 7 in 2008 would have lower viability ratings than 1997 Alternative 11, and 2008 Alternatives 1, 2, 3, 5, and 6 would have higher ratings. These higher ratings are because of a smaller managed land base, the addition of goshawk/marten (in the case of 2008 Alternative 5) or legacy (in the case of 2008 Alternatives 1, 2, 3, and 6) standards and guidelines.

The same relative ratings are also expected to hold for the 2007 Forest Plan versus the 2008 alternatives (i.e., 2008 Alternatives 4 and 7 would have lower viability ratings and 2008 Alternatives 1, 2, 3, 5, and 6 would have higher viability ratings than the 2007 Forest Plan). The moderate viability rating for marten in the 2007 Forest Plan was based on the 1997 plan without the additional conservation measures for marten added in the Decision. With those additional measures, the likelihood of maintaining habitat for viable populations of marten was strengthened. Similarly, Alternative 6 strengthens this likelihood by retaining the additional measures that were added for the 1997 Decision except for the replacement of the Legacy standard for one of the marten measures. This, plus the other additions described in Chapter 2, is why both Alternatives 5 and 6 would have higher viability ratings than the 1997 Forest Plan These conclusions follow the same reasoning as given in the above paragraph for most of the alternatives and are similar to those given in Table D-18 for goshawks.

3.5.3. Alexander Archipelago Wolf

Alternatives 1 and 2 in 2008 would have midpoint values suggesting a very high viability rating for the wolf and Alternative 3 would have a high rating, based on applying Table D-16 equivalencies and rankings to Table D-11. Alternatives 5 and 6 in 2008 are both similar to 1997 Alternative 11, which had a midpoint value of 90. As a result, 2008 Alternatives 5 and 6 are rated at the high end of the high category. Alternative 4 in 2008 is also rated as high, because the midpoint value for 1997 Alternatives 10, 3, and 6, ranges from 79.5 to 91. Alternative 7 in 2008 is equivalent to 1997 Alternative 2 with a midpoint value of 80, which is in the moderately high range.

Given these factors, the rankings of the 2008 alternatives relative to the 1997 selected alternative (Alternative 11) would be as follows: Alternatives 4 and 7 in 2008 would have lower viability ratings than 1997 Alternative 11, and 2008 Alternatives 1, 2, and 3 would have higher ratings. Alternatives 5 and 6 in 2008 would have similar ratings, albeit slightly higher. The same relative ratings are also expected to hold for the 2007 Forest Plan versus the 2008 alternatives (i.e., 2008 Alternatives 4 and 7 would have lower viability ratings and 2008 Alternatives 1, 2, 3, 5, and 6 would have higher viability ratings than the 2007 Forest Plan).

3.5.4. Brown Bear

Alternative 1 in 2008 would have a midpoint value suggesting a very high viability rating for the brown bear, based on applying Table D-16 equivalencies and rankings to Table D-12. Based on the level of POG harvest, 2008 Alternatives 2, 3, 5, and 6 are expected to have high ratings. Alternative 4 in 2008 would be rated as moderately high, because the midpoint value for 1997 Alternatives 10, 3, and 6, ranges from 70 to 78 and averages below 76. Alternative 7 in 2008 is equivalent to 1997 Alternative 2 with a midpoint value of 69.5, which is also in the moderately high range.

Given these factors, the rankings of the 2008 alternatives relative to the 1997 selected alternative (Alternative 11) would be as follows: Alternatives 4 and 7 in 2008 would have lower viability ratings than

1997 Alternative 11, and 2008 Alternatives 1, 2, and 3 would have higher ratings. Alternatives 5 and 6 in 2008 would have similar ratings, albeit slightly higher. The same relative ratings are also expected to hold for the 2007 Forest Plan versus the 2008 alternatives (i.e., 2008 Alternatives 4 and 7 would have lower viability ratings and 2008 Alternatives 1, 2, 3, 5, and 6 would have higher viability ratings than the 2007 Forest Plan).

3.5.5. Other Terrestrial Mammals

Alternative 1 in 2008 would have a midpoint value suggesting a high viability rating for widely distributed mammals and a moderate rating for endemic mammals, based on applying Table D-16 equivalencies and rankings to Tables D-13 and D-14. Based on the level of POG harvest, 2008 Alternatives 2 and 3 are expected to have moderately high ratings for widely distributed mammals and moderate ratings for endemic mammals, respectively. Alternatives 5 and 6 in 2008 are both similar to 1997 Alternative 11, which had a midpoint value of 60 for the widely distributed group and 37 for the endemic group. In addition, 2008 Alternatives 5 and 6 both include supplemental measures (see Section 3.3.2.3), which were not considered in the panel assessments and these measures may have a positive effect on viability; these measures include the survey requirement, connectivity guideline, and goshawk and marten standards and guidelines for 2008 Alternative 5 and the survey requirement, connectivity guideline, and legacy standards and guidelines for 2008 Alternative 6. As a result of this and the midpoint values for 1997 Alternative 11, 2008 Alternatives 5 and 6 are rated at the high end of the moderate category for the widely distributed group and at the low end of the moderate category for endemics. Alternative 4 in 2008 is also rated as moderate for the widely distributed group because the midpoint value for 1997 Alternatives 10, 3, and 6, ranges from 36.5 to 54. This alternative is rated as moderately low for endemics (midpoint ranges from 31 to 35). Alternative 7 in 2008 is equivalent to 1997 Alternative 2 with midpoint values of 10.5 and 4 for the widely distributed and endemic groups, respectively. This places it in the moderately low and very low categories for the widely distributed and the endemic groups, respectively.

Given these factors, the rankings of the 2008 alternatives relative to the 1997 selected alternative (Alternative 11) would be as follows: Alternatives 4 and 7 in 2008 would have lower viability ratings than 1997 Alternative 11, and 2008 Alternatives 1, 2, 3, 5, and 6 would have higher ratings. The same relative ratings are also expected to hold for the 2007 Forest Plan versus the 2008 alternatives (i.e., 2008 Alternatives 4 and 7 would have lower viability ratings and 2008 Alternatives 1, 2, 3, 5, and 6 would have higher viability ratings than the 1997 Forest Plan).

3.5.6. Marbled Murrelet

Alternatives 1, 2, and 3 in 2008 would have midpoint values suggesting a very high viability rating for the marbled murrelet, based on applying Table D-16 equivalencies and rankings to Table D-15. Alternatives 5 and 6 in 2008 are both similar to 1997 Alternative 11, which was not rated by the panel; however, based on the values assigned to the 1995 versions of Alternatives 3, 4, and 5, the 2008 Alternatives 5 and 6 would also fall into the very high viability category. Alternative 4 in 2008 is rated as high, because the midpoint value for the 1995 versions of Alternatives 3 and 6 range from 77 to 90.5. Alternative 7 in 2008 is equivalent to the 1995 version of Alternative 2, but with less harvest. It is given a moderately high viability rating for the marbled murrelet because the midpoint value for the 1995 version of Alternative 2 was 71.5.

Given these factors, the rankings of the 2008 alternatives relative to the 1997 selected alternative (Alternative 11) would be as follows: Alternatives 4 and 7 in 2008 would have lower viability ratings than 1997 Alternative 11, and 2008 Alternatives 1, 2, and 3 would have higher ratings. Alternatives 5 and 6 in 2008 would have similar ratings, albeit slightly higher. The same relative ratings are also expected to hold for the 2007 Forest Plan versus the 2008 alternatives (i.e., 2008 Alternatives 4 and 7 would have lower viability ratings and 2008 Alternatives 1, 2, 3, 5, and 6 would have higher viability ratings than the 2007 Forest Plan).

3.6. Alternative Approach to Viability Evaluation for Alternative Comparison

To determine whether the alternatives provided sufficient habitat to sustain all indigenous wildlife across the planning area, and as a means to compare the alternatives, the 1997 Forest Plan FEIS relied, in part, on the findings of structured panel assessments. As described above, these panel assessments provided estimates of the relative risk, in the form likelihood points or scores for a certain outcome. Results from this assignment of likelihood points do not represent probabilities in the classic sense of frequencies; rather, they represent degrees of belief in future outcomes that are based on reasoned professional judgment and expressed in a probability-like scale (Shaw 1999). Scores from individual panel members were averaged to produce a likelihood score for five possible outcomes related to population distribution for each species: occupancy of historic range (Outcome I), temporary gaps in distribution (Outcome II), permanent gaps in distribution (Outcome III), existence in refugia (Outcome IV), and extirpation from Federal lands (Outcome V).

Other considerations to assess viability were presented in Section 3.4. In order to increase the confidence in our viability assessment, an alternate method for alternative comparisons to address viability was used, The tool with the most applicability to the Tongass, given the lack of level of information required for most other tools, is the analysis presented by Smith and Zollner (2005). They argued that using the most vulnerable species to assess impacts of land management likely underestimates the probability of extinction of wildlife species across the planning area because the risk of local extirpation increases with the number of extinction prone species considered. Since the Tongass is an island archipelago with natural inherent risks of species extripation, this method presents a conservative method to further assess viability risks. The authors present an alternative method for assessing risk to wildlife viability that considers the risk of “any” extinction among species at risk in the planning area. To accomplish this, an equation is used which calculates the joint probability of at least one extinction among the set of selected species. That is, it takes into account the marginal, or individual, extinction probability of each species, as determined by population viability analysis or panel assessment, to compare the relative, rather than absolute, risk of extinction among land management alternatives (see Smith and Zollner (2005) for the equation and for statistical details).

This method was used to rank the 2008 FEIS alternatives in terms of relative level of risk of any of the evaluated species existing in refugia or being extirpated using the 1997 FEIS panel assessment ratings. It is important to note that, since the panel scores for outcomes do not represent probabilities, this approach simply produces risk indices. Two risk indices were calculated: one is based on the likelihood that any species will exist in refugia or be extirpated after 100 years of Forest Plan implementation and the other is based on the likelihood that any species will be extirpated.

This method (which applies the binomial theorem) requires that responses of species at risk to management alternatives be independent (i.e., they cannot respond identically to the management scenario or be ecologically dependent on each other as in predator/prey interactions; Smith and Zollner 2005). The individual species and groups selected for risk assessment panel evaluation were chosen because their ecologies likely incorporate the breadth of forest habitat features and other attributes of environmental variation represented across the Forest (Shaw 1999) and are, therefore, assumed to be independent for this analysis; however, it is recognized that some degree of correlation between components is inherent in all ecological communities.

Table D-19 presents the risk indices for 2008 Alternatives 4, 5/6, and 7, which are equivalent or similar to 1997 Forest Plan FEIS Alternatives 6, 11, and 2 (which were evaluated by the panels), respectively. Applying this risk assessment method indicates that, when all evaluated species are considered jointly, Alternatives 4 and 7 would have the greatest risks. This difference is driven primarily by potential risks to the endemic and widely distributed mammals groups, which have the highest risks of any species or group evaluated (Table D-19). The risk index for extirpation was near 40 percent for both Alternatives 4 and 7, but only 8 percent for Alternatives 5 and 6. The risk index for any species existing in refugia or

[1/] Derived from the 1995 (Alternative 4) and 1997 (Alternatives 7 and 11) panel assessment ratings for Outcomes IV and V; Alternatives 4, 5, and 7 are equivalent to the 1997 Forest Plan FEIS Alternatives 6, 11, and 2, respectively. See Smith and Zollner (2005) for equation and further statistical discussion. Values are relative.

[2.] Endemic group includes small mammals whose known distribution in southeast Alaska (beaver, ermine, voles, etc); wide ranging group includes

[3/] Within each guild, evaluators selected what they considered to be the most sensitive species or group of species to evaluate the effect of each alternative on the guild, sometimes consisting of a few or even one species, depending on geographic distribution of species or management actions (Shaw 1999). For the risk assessment these groups were treated similarly to the single species panels.

being extirpated was greater than 99 percent for Alternative 7, 90 percent for Alternative 4, and 66 percent for Alternatives 5 or 6. Again, it is important to understand that these numbers represent an index of relative risk that any species may exist in refugia or be extripated after 100 years of maximum levels of timber harvest allowed in each Alternative. This relative risk is used to compare alternatives and therefore, it is not accurate to consider these as absolute indicators of a degree of risk.

Because 2008 Alternatives 1, 2, and 3 would harvest less timber than Alternative 5 or 6, but maintain equivalent or more protective conservation measures, it can be assumed that their risk indices would be lower than the corresponding indices for Alternatives 5 and 6. The lowest risk indices would be associated with Alternative 1.

The fact that Alternative 4 had an overall probability of extirpation that was slightly higher than Alternative 7, despite proposing less harvest, is likely due to the fact that risk assessment panels convened twice, once in 1995 and once in 1997, evaluating different alternatives each time. The 1997 FEIS Alternative 2 (equivalent to the 2008 Alternative 7) was assessed both times, whereas 1997 FEIS Alternative 6 (equivalent to the 2008 Alternative 4) was only assessed in 1995. In 1997, there was a consistent shift in outcome ratings for Outcome V, or local extirpation (points shifted to higher outcomes, generally IV), across all alternatives due to a clarification of the interpretation of extirpation within the 100-year evaluation period (Iverson 1997). Also, the acreage potentially harvested under the version of Alternative 6 reviewed by the 1995 panel was higher than the level of harvest for the 1997 Alternative 6 and for the 2008 Alternative 4. Thus, it is likely that if the 1995 version of Alternative 6 had been reevaluated in 1997, its score for Outcome V would also have shifted down, lower than the 1997 version of Alternative 2 (re-ordering the results to show that Alternative 7 considered here would in fact pose the greatest risk to the ecological community). Taking this factor into account, the overall outcomes confirm the relative rankings of the alternatives based on other comparisons.

4. CONCLUSIONS REGARDING THE 2008 FOREST PLAN AMENDMENT

4.1. Introduction

The conservation strategy provides the scientific basis for an ecological approach to the Tongass Forest Plan. The strategy consists of a system of OGRs and matrix lands that are a mix of retention and active forest management. The Forest-wide reserve network provided by the non-development LUDs provides the backbone framework to ensure maintenance of habitat for species viability while the matrix provides a variety of functions and activities. Both are critical for the conservation strategy and to ensure species viability; however, they have different functions.

The reserve network protects the integrity of the old-growth forest ecosystem by protecting the largest blocks of contiguous old growth, as well medium and smaller-sized blocks. These reserves are distributed across the Forest and serve as core areas for functioning old-growth ecological communities.

The forests in the matrix provide a variety of functions, including connectivity between old growth in reserve areas and providing habitat for a variety of organisms associated with forests of a variety of successional stages, including old growth. Standards and guidelines within the matrix are designed to provide for important ecological functions such as dispersal of organisms, carryover of some species from one stand to the next and maintenance of ecologically valuable structural components such as down logs, snags and large trees. The expected condition for the matrix over time, given all Forest Plan expectations, is a mosaic of successional stages – from early seral to second growth forests to old-growth forests. The suite of ecological functions provided by the matrix, including connectivity and old-growth representation, is achieved through the combination of old growth retention in beach fringe, riparian and floodplain buffers, karst, soil, other no-harvest areas; aging young-growth stands; uneven-aged managed stands; and patches of forest left in managed stands. Matrix functions are enhanced, both in the short term and as the stand ages, by leaving individual reserve trees, snags and clumps of reserve trees within harvested units.

4.2. Forest-wide Reserve Changes

Changes to the conservation strategy under the alternatives fall into two broad categories (as described in Sections 2.5.1 and 2.5.2): changes to the Forest-wide reserve network and changes to standards and guidelines that affect management of the matrix. The overall effects of these changes need to be examined in combination to determine the net effects of the changes relative to the 2007 Forest Plan (modeled by Alternative 5). This section summarizes these overall effects.

As noted in Section 2.5.1, the Forest-wide reserve network was modified in two ways: changes were made to the areas identified as Old-Growth Habitat LUDs and changes were made to other non-development LUDs. Under Alternatives 1, 2, 3, and 6, the boundaries of a large portion of the Old-Growth Habitat LUDs that represent the small OGRs were modified using a process that started with an interagency biological proposal and ended with a refinement of that proposal in consideration of multiple-use objectives. The net result of these modifications was an increase in OGR acres by 39,000 relative to Alternative 5 (the 2007 Forest Plan). In contrast, Alternative 4 reduces the acreage in Old-Growth Habitat LUDs by 789,000 or 67 percent and Alterative 7 totally eliminates the Old-Growth Habitat LUD.

The second way that the Forest-wide reserve network was modified was through the modification of other non-development LUDs, which also represent an important part of the network. Overall, the acreage in these other non-development LUDs was also enlarged under Alternatives 1, 2, 3, and 6 relative to Alternative 5, and reduced under Alternatives 4 and 7.

Table D-5 provides a summary of these changes in reserve area relative to Alternative 5. This table demonstrates that the land area in reserves under Alternative 6 (proposed action) has increased by 149,000 acres relative to Alternative 5. This represents an increase of approximately 1 percent of the Forest land area (i.e., reserve acreage represents 79.4 percent of the Forest under Alternative 6 and 78.5

percent under Alternative 5). An increasingly greater percentage of the Forest would be in reserves under Alternatives 3, 2, and 1 (83.3, 88.5, 95.0 percent, respectively). Under Alternatives 4 and 7, the acreage in reserves would be reduced to 71.8 and 69.9 percent of the Forest, respectively.

Table D-6 summarizes these changes relative to POG. Under Alternative 6, the acreage of POG in reserves would be 45,000 acres greater than under Alternative 5, while the acreage of POG that is protected in the matrix would be 28,000 acres less than under Alternative 5, resulting in a net increase of 17,000 acres. In addition, the percentage of high-volume and large-tree POG that is protected in reserves would increase under Alternative 6, relative to Alternative 5, primarily because of the changes made to OGRs and other LUDs; these changes resulted in a greater portion of the forest types consisting of larger trees being included within reserves. Under Alternative 6, for example, 72.6 percent of the high-volume POG and 69.9 percent of the large-tree POG would be included within reserves compared with 71.3 and 67.8 percent under Alternative 5, respectively. Overall, 90.1 percent of the existing high-volume POG and 89.0 percent of the large-tree POG would not be harvested under Alternative 6, compared with 88.9 and 88.6 percent under Alternative 5. Again, an increasingly greater percentage of total POG and the larger tree POG types would be protected in reserves and in overall under Alternatives 3, 2, and 1, in that order. In contrast, a significantly smaller percentage of total POG and the larger tree POG types would be protected in reserves and overall in Alternatives 4 and 7, in decreasing order.

4.3. Standards and Guidelines Changes

The other major factors to be considered in comparing the overall effects of changes to the conservation strategy are the changes to standards and guidelines. Most changes to the standards and guidelines under Alternatives 1, 2, 3, and 6 are minor and it was concluded in the previous subsections that they would not affect the strategy. The one change to the standards and guidelines that is more far-reaching and needs to be considered in combination with the LUD changes is the replacement of the goshawk and marten standards and guidelines with the legacy standard and guideline. The legacy standard provides an alternative, more ecological approach to conserving wildlife habitat at the project scale as compared to the more species-specific marten and goshawk standards. This approach simplifies the standard, allows equal to greater flexibility, and leaves representative components of old growth in high risk VCUs outside of the biogeographic provinces covered by the marten and goshawk standards.

For marten, ADF&G harvest reports continue to indicate stable or increasing marten populations across the Tongass and trapping continues to occur across the entire Tongass under both State regulations and federal subsistence regulations. While there is increased knowledge regarding the distribution of two marten lineages (*caurina* and *americana*), there is no indication of differential life history requirements or habitat use between lineages. Therefore, maintaining one set of marten standards is still appropriate. The legacy standard would continue to retain additional forest structure in VCUs with the highest level of harvest in high risk marten provinces and this is still valid, based on concerns about the ability of marten to travel through landscapes that have large openings due to past timber harvest.

No barriers to movement other than open salt water have been identified and marten travel through a variety of habitats including clearcuts, muskeg openings and roads. Marten will continue to move through the matrix using riparian and beach buffer routes, as well as crossing the mix of natural and human-caused openings. Since trapping access and trapping success can increase where there are roads, the standard requiring road management considerations is maintained, where marten mortality is directly attributed to road access.

Considering the combination of the OGR network, non-development LUDs and retention of old growth via various standards and guidelines, there is significantly more high value marten habitat retained than just in OGRs. Recent studies indicating that OGRs may not be of sufficient sizes to maintain marten do not adequately take into account the amount of other old growth retained in the Forest Plan and, thus, do not reflect how much actual marten habitat would remain. Slightly more than two-thirds (68 percent) of all existing old growth within the matrix would remain unharvested after 100 years of Forest Plan implementation (at the maximum allowable harvest rate) under either Alternative 5 or Alternative 6. Thus, lands outside of the reserves will provide more than just connectivity for marten. Given timber harvest trends (smaller-sized openings coupled with decreased harvest levels), the continued succession of young growth to mature forest, and the value and amount of old growth retained outside of OGRs, it appears that the assumptions of these studies were very conservative and do not reflect available marten habitat under actual Forest Plan implementation. Based upon this analysis, implementation of Alternatives 1, 2, 3, or 6 with the legacy standard would not reduce the likelihood of maintaining habitat that supports well-distributed marten populations, relative to Alternative 5. Based on the viability panel analysis (Section 3), there is at least a moderate likelihood that sufficient habitat would be maintained to support a viable and well distributed marten populations across the Tongass under these alternatives. While it is anticipated that there could be gaps in this distribution, there is a low likelihood that there would be significant isolation among marten populations resulting from implementation of the amended Forest Plan.

For goshawks, based upon these analyses, Alternatives 1, 2, 3, and 6 would provide a sufficient amount and distribution of habitat to maintain viable and well distributed populations across the Tongass after 100 years of Forest Plan implementation. The legacy standard and guideline would continue to retain additional forest structure in harvest units greater than 20 acres in all VCUs on Prince of Wales Island that were identified as concerns for goshawk, and this is still valid, based on concerns about goshawks specific to this island. In addition, the legacy standard would also retain forest structure in other VCUs forest-wide, which provides an additional measure of protection for goshawk habitat outside of Prince of Wales Island.

These analyses assumed maximum allowable timber harvest every decade for 100 years of implementation of the Forest Plan. The interagency assessment called *The Conservation Assessment for the Northern Goshawk in Southeast Alaska* (Iverson et al. 1996) defined three categories of VCU harvest and related those categories to the likelihood of the VCU continuing to support goshawks. These categories were based on the concept of a 300-year ecological rotation. The three categories were: 1) <33 percent POG harvest = high likelihood that VCU supports goshawks; 2) 33-47 percent POG harvest = slightly increased risk that VCU will not support goshawks; and 3) >47 percent = increased risk that VCU will not support goshawks.

The proportion of the Tongass acreage that falls into these categories was estimated for those VCUs that originally contained a significant amount of goshawk habitat (defined as a minimum of 2,300 acres of POG). For this appendix, the three categories were applied to Alternative 6 and the results are summarized below:

- An estimated 95 percent of the goshawk range on the Tongass currently has a high likelihood of sustaining goshawk habitat (< 33 percent of old-growth harvested).
- An estimated 95 percent of the goshawk range on the Tongass would have 47 percent or less of the POG harvested after 100 years of Forest Plan implementation, and would maintain a relatively high likelihood of sustaining goshawks.
- An estimated 12 percent of the goshawk range on the Tongass would have a slightly elevated risk of not sustaining goshawks, with between 33 and 47 percent of the old growth harvested after 100 years.
- Most elevated risk landscapes (> 47 percent harvested) would be aggregated on North and Central Prince of Wales Island. This province only represents 9 percent of the acreage comprising goshawk range on the Tongass.
- Where risks would be elevated by matrix management intensity, remaining very high quality goshawk habitats would be protected by forest-wide standards and guidelines

These results, together with the viability panel analysis described in Section 3 and the other related analyses presented in Section 2.5, lead to the conclusion that implementation of Alternatives 1, 2, 3, or 6 with the legacy standard would not reduce the likelihood of maintaining habitat that supports viable and well-distributed goshawk populations relative to Alternative 5. Based on the viability panel analysis (Section 3) there is at least a high likelihood that sufficient habitat would be maintained to support viable and well distributed goshawk populations across the Tongass under these alternatives.

In contrast, the modifications to the standards and guidelines under Alternatives 4 and 7 (e.g., no legacy or goshawk/marten standards and guidelines under either alternative and reduced beach fringe and elimination of Class III stream buffers under Alternative 7), coupled with their significantly lower acreages of protected POG, particularly in reserves, leads to the conclusion that the likelihood of maintaining habitat that supports well-distributed marten and goshawk populations could be compromised. The potential effect would be substantially greater under Alternative 7. However, based on the viability panel analysis (Section 3) there is a moderate likelihood for marten and a moderate to moderately high likelihood for goshawks, that sufficient habitat would be maintained to support viable and well distributed populations across the Tongass under these alternatives. In addition, even under Alternative 4 or 7, the potential effect would not be realized unless harvest levels occurred and were maintained at a much higher rate than has occurred in the past 10 years. Given this, and given the 10 to 15-year timeframe until the Forest Plan is revised again, it is highly unlikely that these levels of harvest would occur before the next Forest Plan revision.

4.4. Summary and Conclusions

In summary, the numbers reviewed in Section 2.5 reflect the changes in reserves as well as the changes in standards and guidelines (including the replacement of the goshawk and marten standards and guidelines with the legacy standard and guideline). Although there is some shift of POG from the matrix to POG in reserves, the net effect of all LUD and standard and guideline changes is an increase in protected POG (including the larger tree POG types) under Alternatives 1, 2, 3, and 6, relative to Alternative 5. The 1997 Forest Plan FEIS analysis of Alternative 11 (without consideration of specific additional goshawk and marten standards and guidelines) stated that the 1997 Alternative 11 was explicitly designed to address issues related to wildlife viability conservation planning. It was projected to have a moderately high likelihood of maintaining viable, well distributed populations of old-growth associated species across the Tongass National Forest (USDA Forest Service 1997c). Alternatives 1, 2, 3, and 6 of the 2008 Forest Plan Amendment FEIS do not negatively affect the conservation strategy that this conclusion was based on; in fact, the acreage in reserves and the acreage of old growth in reserves would be higher and the total protected POG would be slightly higher. These positive effects would occur under Alternatives 6, 3, 2, and 1, in increasing order. Alternatives 4 and 7, on the other hand, would negatively affect the conservation strategy and would reduce the likelihood of maintaining viable, well-distributed populations. Alternative 7 would have the greatest potential to negatively affect the strategy. Under any alternative, however, the maximum effects that these conclusions are based on depend on actual harvest levels occurring at a rate significantly higher than under the recent past.

APPENDIX E
CATALOGUE OF PAST HARVEST

Appendix E

Catalogue of Past Harvest

CONTENTS

Appendix E
Catalogue of Past Harvest

Introduction

This appendix presents a catalogue of past harvest for Southeast Alaska. It is based on updated and extensive mapping of past harvest based on the Tongass GIS library, GIS data layers provided by Sealaska Regional Native Corporation, the State of Alaska, and Audubon Alaska/The Nature Conservancy, as well as supplemental interpretation of orthophotography and other aerial photography. It is also based on tabular information collected from the State of Alaska, Department of Natural Resources regarding state harvests and harvests under the Alaska Forest Resources and Practices Act. Appendix B provides more detailed information on the inventory methodology.

Part I of this appendix provides a tabular catalogue of harvest acreage by ownership category, landowner, and biogeographic province. An approximate harvest period is listed by decade as well. Part II presents a tabular summary of information provided by the State of Alaska Department of Natural Resources, Division of Forestry.

Part I – Acreage of Past Harvest by Ownership Category, by Landowner, by Biogeographic Province, by Approximate Decade

Ownership Category	Landowner	Est. Approx. Harvest Decade	Acres Harvested
Yakutat Forelands Biogeographic Province			
Tongass National Forest	Tongass National Forest	1950s	28

Part II – Statistics on the Alaska Forest Resources and Practices Act Implementation and State Timber Sales in Southeast Alaska

Part II presents a tabular summary of information provided by the State of Alaska Department of Natural Resources, Division of Forestry. Statistical information is not available for harvests prior to the Alaska Forest Resources and Practices Act (AFRPA), nor for some years since the Act. Tables E-1 through E-5 provide statistics regarding the AFRPA, as it has been applied to private and other lands in Southeast Alaska. Tables E-6 through E-17 provide information on State timber sales in Southeast Alaska.

APPENDIX F
BIOLOGICAL ASSESSMENT

Appendix F

Biological Assessment

CONTENTS

LIST OF TABLES

Appendix F
Biological Assessment

Introduction

Under Section 7 of the Endangered Species Act (ESA), federal agencies are required to ensure that actions are not likely to jeopardize the continued existence of a listed species. This is done in a report called a "Biological Assessment." The effects analysis for threatened and endangered (T&E) species is required to address the direct and indirect effects of the action(s) on T&E species and their critical habitat (50 Code of Federal Regulations [CFR] 402.02). This documentation complies with Section 7 of the ESA which requires all federal agencies, in consultation with the U.S. Fish and Wildlife Service (USFWS) and the National Marine Fisheries Service (NMFS), to ensure that their actions are not likely to jeopardize the continued existence of T&E species or adversely modify their habitat. It updates previous Biological Assessments for the Tongass Plan Revision dated October 1996 (previous versions were also completed in August 1990 and April 1992).

This biological assessment complies with the Forest Service Manual (FSM) 2672.4 and documents the potential direct and indirect effects of the proposed alternatives (including the Proposed Action) and the cumulative effects of past, present, and reasonably foreseeable actions within the project area or adjacent lands on the critical habitats and viability of any federally listed or USDA Forest Service sensitive listed species. Species considered in this assessment include any species listed as threatened, endangered, proposed, or candidate by USFWS or NMFS.

Six wildlife species and one plant species under the jurisdiction of USFWS are found (or were once found) in Alaska: Kittlitz's murrelet (*Brachyramphus brevirostris*), the recently listed northern sea otter (*Enhydra lutris kenyoni*), short-tailed albatross (*Phoebastria albatrus*), Eskimo curlew (*Numenius borealis*), spectacled eider (*Somateria fischeri*), Alaska breeding population of Steller's eider (*Polysticta stelleri*), and Aleutian shield fern (*Polystichum aleuticum*). Except for the Kittlitz's murrelet, which is a candidate for listing under ESA, none of these species is found in Southeast Alaska, and will not be discussed further in this biological assessment.

Additionally, a number of marine threatened and endangered species fall under the jurisdiction of NMFS. These species are at least occasionally, or historically have been, found in Southeast Alaska. They include the leatherback sea turtle (*Dermochelys coriacea*), eastern population of Steller sea lion (*Eumetopias jubatus*), small numbers of the western population of Steller sea lion (*E. jubatus*), fin whale (*Balaenoptera physalus*), northern right whale (*Eubalaena japonica*), blue whale (*B. musculus*), and humpback whale (*Megaptera novaeangliae*). In addition to the above listed species, the Cook Inlet beluga whale Distinct Population Segment (DPS) has been proposed for listing as endangered. Furthermore, one sockeye salmon (*Onchorynchus nerka*), six chinook salmon (*O. tshawytscha*), one chum salmon (*O. keta*), and six steelhead trout (*O. mykiss*) evolutionarily significant units (ESUs)/DPSs are currently listed under ESA and are known to seasonally inhabit the marine waters of Southeast Alaska (Table F-1). However, of all these species, the Steller sea lion and humpback whale are known to occur in Southeast Alaska, while 14 of the 28 listed salmon and steelhead trout stocks shown in Table F-1 occur in Southeast Alaska's marine waters.

This combined assessment addresses 12 threatened species, 5 endangered species, and 1 candidate (Table F-1)[1]. These are the only T&E listed species addressed further in this assessment. The listed species covered are divided into two sections: those under the jurisdiction of USFWS (Kittlitz's murrelet), and those under the jurisdiction of NMFS (the remaining 17 species).

[1] Note that the eastern stock of the Steller sea lion is listed as threatened, and the western stock is listed as endangered. As a result, Steller sea lion is included in this count as a threatened species and an endangered species.

1/ NMFS defines "species" under the ESA to include evolutionarily significant units (ESUs) for salmon and distinct population segments (DPSs) for steelhead.
2/ Distribution from NMFS 2003.
3/ The eastern stock of the Steller sea lion is listed as threatened, and the western stock is listed as endangered.
4/ DPS that were listed since 2004. Alaska distribution assumed.

Section 1. Biological Assessment for Kittlitz's murrelet for the Tongass Forest Plan Adjustment

November 2007

This section addresses the potential direct and indirect effects of the proposed alternatives on threatened, endangered, proposed, or candidate species managed by the USFWS pursuant to Section 7 consultation requirements of the ESA. This Biological Assessment updates a previous Biological Assessment for the Tongass Plan Revision (dated October 1996). This update includes these changes to the previous Biological Assessment:

- The USFWS published a final rule in the Federal Register (USFWS, 1999) delisting the Peregrine Falcon from the Threatened species list. This species is listed as Forest Service Sensitive.
- The Kittlitz's murrelet was officially designated a candidate species (warranted, but precluded) on May 4, 2004.

I. Identification of Endangered, Threatened and Candidate Species and/or Critical Habitats for Such Species within the Project Area.

On May 9, 2001, the Secretary of the Interior was petitioned to list the Kittlitz's murrelet (*Brachyramphus brevirostris*) as endangered with concurrent designation of critical habitat under the ESA. Petitioners cited dramatic reductions in population size over the past decade and declining habitat quality as reasons for the requested listing. On May 4, 2004, the Kittlitz's murrelet was designated a candidate species.

Common Name	Scientific Name	ESA Status
Kittlitz's murrelet	*Brachyramphus brevirostris*	Candidate

II. Overview of Species Distributions, Populations and Habitats.

The Kittlitz's murrelet is closely associated with glacial habitats along the Alaska mainland coast. Breeding sites are usually chosen in the vicinity of glaciers and cirques in high elevation alpine areas, with little or no vegetative cover (Van Vliet 1993). When present, vegetation is primarily composed of lichens and mosses (Day et al. 1983). The species nests a short distance below the peak or ridge on coastal cliffs, barren ground, rock ledges, and talus above timberline in coastal mountains, generally near glaciers 0.2 to 47 miles inland (Day et al. 1983). The remote and solitary nesting habits lead to extreme difficulty in finding nests. Non-breeding or off-duty breeders spend the summer in inshore areas, especially along glaciated coasts.

The Kittlitz's murrelet is one of the rarest seabirds in North America. The only American population occurs in Alaskan waters from Point Lay south to northern Southeast Alaska (Endicott and Tracey Arm). The largest breeding populations are believed to be in Glacier Bay National Park and Preserve, Prince William Sound, Kenai Fjords, and Icy Bay (Kendall and Agler 1998). According to the petition, the southern boundary of the breeding range is LeConte Bay on the Tongass National Forest. Latest worldwide population estimates range from 9,500 to 26,500 birds. The best information available from the USFWS indicates that Prince William Sound populations have declined by 84 percent since 1984, Kenai Fjords area by 83 percent since 1976, Malaspina Forelands by 38 percent and perhaps as much as 75 percent between 1992 and 2002, and Glacier Bay by 60 percent between 1990 and 1999. Speculated causes for decline include oil pollution, glacial recession, gill-net mortality, and availability of preferred forage fish (Kuletz et al. 2003, Piatt and Anderson 1996, van Vliet and McAllister 1994). Effects of these factors include increased adult and juvenile mortality and low recruitment. Human-caused mortality includes gillnet fisheries and oil spills like that from the Exxon Valdez or smaller tourism and fishing boats. Increased disturbance from helicopter tours and cruise ships may also be a factor.

III. Assessment of Effects on the Populations or Habitats of the Species In Relation to Proposed Actions of the Tongass Forest Plan Adjustment.

Due to the Kittlitz's murrelet's association with glacial habitat, this species occupies areas outside of where timber harvest and associated activities have occurred or are likely to occur. Major threats to this species are global warming, which is correlated with a loss of suitable habitat (glacial melt) and reduction in prey availability due to warming sea temperatures. Human activity in the marine environment, particularly vessel traffic and fishing operations, are additional threats to this species. There is no indication that any Forest Service management activity is affecting the Kittlitz's murrelet (USDA Forest Service 2004). Consequently, implementing any of the alternatives will not directly or indirectly affect the Kittlitz's murrelet.

Forest-wide standards and guidelines have been developed for protecting seabird rookeries and waterfowl concentration areas (Attachment 1). Adverse effects on Kittlitz's murrelet populations or their habitats are not anticipated with any Forest management activities.

Relationship with other Agencies and Plans

The USFWS has responsibility for the Kittlitz's murrelet. Recovery Plans have not been developed for this species. No critical habitat has been designated in Southeast Alaska to date.

Determination for Kittlitz's Murrelet

Based upon this analysis, the Adjustment of the Tongass National Forest Land Management Plan *will not likely jeopardize the continued existence of Kittlitz's murrelet, or adversely modify proposed critical habitat (if it were to be proposed).*

In addition, formal and informal consultation procedures (as directed by the ESA, as amended, and 50 CFR 17.7, and FSM 2670) are used with the USFWS on all projects within areas that may be used by Kittlitz's murrelet. Forest-wide standards and guidelines for threatened and endangered species (Chapter 4 - Wildlife) direct all projects to follow requirements of the ESA and Forest Service Policy (FSM 2670).

Documentation of Correspondence with other Agencies

Consultation with USFWS occurred throughout the 1997 Forest Plan Revision process and was initiated by the Forest Service in September 1987 with written letters requesting a list of threatened, endangered, proposed, and candidate wildlife species for the Tongass National Forest. At that time, the determination was that the American peregrine falcon was the only listed species that could occur on the Tongass and the evaluation of effects in the Biological Assessment indicated that populations of peregrine falcons would not likely be adversely affected as a result of implementation of the decision. The USFWS concurred with this determination in October 1996. The peregrine falcon was delisted in 1999 and, therefore, not assessed further in this updated Biological Assessment.

For the preparation of this update to the Biological Assessment, current species lists were obtained on the USFWS website accessed most recently in November 2007. The Kittlitz's murrelet was officially designated a candidate species (warranted, but precluded) on May 4, 2004 and therefore is automatically listed as Forest Service Sensitive. In April 2006, the Forest Service hosted an interagency Conservation Strategy Review workshop in Ketchikan, Alaska, which brought together scientists, technical experts, and land managers with expertise in conservation biology and natural resource management from the USFWS, the Alaska Department of Fish and Game (ADF&G), and the Pacific Northwest and Pacific Southwest Research Stations. The workshop provided a forum for the presentation and discussion of relevant scientific information gained since 1997 to be used to inform forest planning decisions. This information has been incorporated into the Forest Plan Amendment EIS and this biological assessment.

Informal consultation was initiated by the Forest Service with the USFWS through a phone conversation on November 21, 2007 (log number 71440-2008-SL-0010) regarding Kittlitz's murrelet. The USFWS concurred that formal consultation was not required.

Section 2. Biological Assessment for the Endangered Humpback Whale, Endangered Western and Threatened Eastern Steller Sea Lion Populations, and Listed Pacific Salmon and Steelhead for the Tongass National Forest Plan Adjustment

November 2007

This section addresses the potential direct and indirect effects of the proposed alternatives on federally-listed species managed by NMFS. This Biological Assessment updates a previous Biological Assessment (dated October 1996,) that was prepared for endangered whales and the threatened Steller sea lion for the Tongass Forest Plan Revision process. NMFS concurred with the Forest Service finding in that Biological Assessment that the proposed revised Tongass Land Management Plan was not likely to adversely affect listed species under the jurisdiction of NMFS. This update includes the following changes:

- Consideration of the endangered western population of Steller sea lion as likely to occur within the coastal waters possibly affected by the proposed action;
- Consideration of 11 additional species of Pacific salmon that were listed since the previous update and may occur within the project area.

I. Identification of Endangered and Threatened Species and/or Critical Habitats for Such Species Within the Project Area.

The following marine mammals and salmon or steelhead stocks under the jurisdiction of NMFS have been identified as possibly occurring within the affected project area and are considered in this assessment.

<u>Marine Mammals</u>
Humpback whale—Endangered
Steller Sea Lion—Threatened: eastern population, Endangered: western population

<u>Fish</u>
Snake River Sockeye salmon—Endangered
Snake River Spring/Summer-run Chinook salmon—Threatened
Snake River Fall-run Chinook salmon—Threatened
Upper Columbia River Spring-run Chinook salmon—Endangered
Lower Columbia River Chinook salmon—Threatened
Upper Willamette River Chinook salmon—Threatened
Puget Sound-run Chinook salmon—Threatened
Columbia River Chum salmon—Threatened
Snake River Basin Steelhead—Threatened
Lower Columbia River Steelhead—Threatened
Middle Columbia River Steelhead—Threatened
Upper Columbia River Steelhead—Endangered
Upper Willamette River Steelhead—Threatened
Puget Sound Steelhead—Threatened

NMFS completed a final recovery plan for the humpback whale in 1991 and for the Steller sea lion in 1992.

There has been no critical habitat officially designated for the whales at this time in Southeast Alaska.

Critical habitat was designated for the Steller sea lion by NMFS in 1993 and represents areas considered essential for the continued survival and recovery of this species (NMFS 1993). The eastern population of Steller sea lion was listed as threatened on November 26, 1990 (55 CFR 40204) and the western population was listed as Endangered on May 5, 1997 (62 CFR 30772). Adult Steller sea lions congregate at rookeries for breeding and pupping. Rookeries are generally located on relatively remote islands, often in exposed areas that are not easily accessed by humans or mammalian predators. These rookeries, as well as haul-outs, have been officially designated as critical habitat in Southeast Alaska (NMFS 2001). NMFS' definition of critical habitat for Southeast Alaska includes a "terrestrial zone, aquatic zone, and an air zone, that extend 3,000 feet landward, seaward, and above, respectively, for each major rookery and major haul-out in Southeast Alaska." Critical habitat provides notice to federal agencies that a listed species is dependent on these areas for its continued existence and that any federal action that may affect these areas is subject to the consultation requirements of Section 7 of the ESA. To date, 3 major rookeries and 11 major haul-outs have been identified in Southeast Alaska (Table F-2).

Table F-2
Major Steller Sea Lion Rookery and Haul-out Habitats in Southeast Alaska

Name	Rookery	Haul-out
Forester Island	X

Timbered Island		X

Source: 50 CFR 226.202, pages 183, 200-203

No ESA-listed stocks of salmon or steelhead originate in Alaskan streams. However many species and stocks are listed that originated from freshwater habitats in Washington, Idaho, Oregon and California (Table F-1). Some of these listed species migrate into marine waters off the coast of Alaska. While distribution of these stocks is primarily in outer coastal waters some are occasionally present in the inner waters of Southeast Alaska and they may feed on prey resources originating within marine and estuarine waters of the Tongass National Forest.

II. Overview of Species Distributions and Populations.

The following summaries for humpback whale, Steller sea lion, and salmonids were abstracted and compiled from information found in the Alaska Marine Mammal Stock Assessments, 2006 (Angliss and Lodge 2007), Glacier Bay Biological Opinion (NMFS 2003a), published scientific literature, and unpublished reports.

Humpback whales were listed as endangered under the ESA in 1973 due to reduced population size that resulted from significant commercial whaling harvest. Currently, no critical habitat has been designated for the humpback whale.

Due to dramatic declines in total population numbers over approximately a 30 year period, the Steller sea lion was listed as threatened under the ESA (55 CFR 40204). In 1997, the Steller sea lion population was split into two separate populations (western and eastern populations) based on demographic and genetic differences (Bickham et al. 1996, 62 CFR 307772).

A total of 28 listed ESU/DPSs of salmon and steelhead occur in the Northeast Pacific (Table F-1). Alhough none of the listed stocks originate from Alaskan streams, 14 could potentially be present in Alaskan waters during some period of their marine life stage.

Humpback Whale

Humpback whales (*Megaptera novaeangliae*) are currently listed as endangered under the ESA, and have been protected since 1965. From the late 1800s through the early 1900s, they were extensively commercially hunted, and their current worldwide population is estimated to be only 8 percent of their historical numbers. Recent population estimates, however, show signs of recovery (Calambokidis et al. 1997, NMFS 2002a).

Humpback whales generally migrate between temperate and tropical waters in the winter and spring where they mate and calve, and cooler northern coastal waters where they feed. Feeding occurs near the highly productive fjords of the Southeastern Alaskan panhandle and Prince William Sound, from approximately May through December, although some individuals can be seen every month of the year (Calkins 1986). Peak numbers of whales are usually found in nearshore waters during late August and September, but substantial numbers usually remain until early winter. Humpbacks summering in Southeast Alaska have been linked to three wintering areas: the coastal waters along Baja California and mainland Mexico, the main islands of Hawaii, and the islands south of Japan (NMFS 1991). Those whales that feed in Southeast Alaska and migrate to Hawaii are referred to as the Central North Pacific stock (NMFS 2002a).

The local distribution of humpbacks in Southeastern Alaska appears to be correlated with the density and seasonal availability of prey, particularly herring (*Clupea harengus*) and euphausiids, and adults consume up to 3,000 pounds a day outside the breeding season. Important feeding areas include Glacier Bay and adjacent portions of Icy Strait, Stephens Passage/Frederick Sound, Seymour Canal and Sitka Sound. Glacier Bay and Icy Strait appear to be an important feeding area early in the season, when whales prey heavily on herring and other small, schooling fishes. Frederick Sound is important later in summer, when whales feed on swarming euphausiids. During autumn and early winter, humpbacks move out of the Sound to areas where herring are abundant, particularly Seymour Canal. Other areas of Southeastern Alaska may also be important for humpbacks and need to be evaluated. These include Cape Fairweather, Lynn Canal, Sumner Strait, Dixon Entrance, the west coast of Prince of Wales Island, and offshore banks such as the Fairweather Grounds.

The Central North Pacific stock of humpback whales was estimated to number 4,005 in 1993 (+/- 746, 95 percent confidence interval) (Calambokidis et al. 1997). A 1997 Forest Service estimate of the Southeast Alaska humpback whale feeding aggregation was 300 to 500 animals (USDA Forest Service 1997) during summer and fall, although a more recent estimate is 961 animals (+/- 226, 95 percent confidence interval) (Straley et al. 2002). The population rate of increase was estimated at 7 percent for Pacific humpback whales during 1993–2000 (Mobley et al. 2001), which may be near the species maximum. They are regularly sighted in the Inside Passage and coastal waters of the Southeastern Alaska panhandle from Yakutat Bay south to Queen Charlotte Sound (USDA Forest Service 1997).

Because the humpback inhabits shallow coastal areas, it is increasingly exposed to human activity. Consequently, these whales may be more susceptible to confrontational disturbance, displacement, and loss of habitat from environmental degradation than some other whale species. Specifically, the greatest threats to humpback whales today are entanglements in fishing gear, ship strikes, and coastal habitat pollution.

Steller Sea Lion

The Steller (northern) sea lion (*Eumetopias jubata*) ranges from Hokkaido, Japan, through the Kuril Islands and Okhotsk Sea, Aleutian Islands and central Bering Sea, Gulf of Alaska, Southeast Alaska, and south to central California (Calkins 1986, National Marine Mammal Laboratory [NMML] 2003). The centers of abundance and distribution are the Gulf of Alaska and Aleutian Islands, respectively.

The Steller sea lion was originally listed under the ESA in 1990 as threatened. At that time, Steller sea lion numbers were declining sharply throughout their range and particularly in Alaska. Populations are estimated to have declined between the 1950s and 1990 by 78 percent (NMFS 1992). In certain parts of Alaska, declines of greater than 80 percent have occurred since 1985. The number of sea lions observed on certain rookeries from Kenai Peninsula to Kiska Island declined by 63 percent since 1985 and by 82 percent since 1960. Critical habitat for Steller sea lions was designated in 1993 (NMFS 1993). Specific causes of the population decline are unknown, although population modeling has suggested that decreased juvenile survival is a likely driver. The declines are spreading to previously stable areas and are accelerating. Significant declines have also occurred on the Kuril Islands.

In 1997, NMFS classified the Steller sea lion as two distinct population segments, the eastern stock (ES) and western stock (WS), and re-evaluated their status. The stock differentiation is based primarily on differences in mitochondrial DNA, but also on population trends in the two regions. Steller sea lions occurring west of 144°W longitude were reclassified as endangered. The eastern Pacific population, still listed as threatened, includes Southeast Alaska and the Tongass National Forest. ES populations are increasing in the northern part of the range (Southeast Alaska and British Columbia) and declining in the southern end of its range (Oregon, Washington, and California). In this region, habitat concerns include reduced prey availability, contaminants, and disease (Sydeman and Allen 1997). Both WS and ES stocks are designated as “depleted” and “strategic” under the Marine Mammal Protection Act (MMPA). Although ES stock size has increased in recent years, its status relative to its optimum sustainable population size is still unknown.

There is some limited interchange between the WS and ES populations. Raum-Suryan et al. (2002, 2004) branded 8,596 sea lion pups from 1975 to 2001, and found that a few juveniles from the WS moved to the ES region. Resightings of branded Steller sea lions showed wide dispersal from natal rookeries, particularly among juveniles, which occasionally traveled over 1,500 km to other rookeries and haul-outs and crossing stock boundaries. However, individuals consistently returned to breed, and no adult Steller sea lions were observed breeding with the opposite stock (Raum-Suryan et al. 2002). A more recent study used satellite transmitters to track distribution and movement patterns of pup and juvenile Steller sea lions from both stocks. Overall, movement of individuals between the WS and ES populations were documented only in very low numbers, and only among males (Raum-Suryan et al. 2004). Although some WS individuals have been observed foraging in Southeast Alaska, the WS Steller sea lion population will not be discussed in greater detail in this assessment because of the extremely low number of sightings and because the existing Standard and Guidelines are not specific to the ES Steller sea lion stock and would therefore protect both populations.

The total estimated population of the ES Steller sea lions is 48,519 or 54,989 in 2002–2005, depending on which assumptions are used to calculate the pup multiplier (see Calkins and Pitcher 1982, Trites and Larkin 1996). The number of ES pups produced has nearly doubled since 1978, with an annual rate of increase of 5.9 percent from 1979 to 1998, although the rate of increase between 1989 and 1997 was only 1.7 percent (Calkins et al. 1999). Sease and Gudmundson (2002) estimated a 1.8 percent annual increase in non-pup sea lions between 1991 and 2002. In the Southeast Alaska portion of the ES, non-pup counts on trend sites have increased 29.3 percent since 1990 (Sease et al. 2001). The estimated abundance of the ES population of Steller sea lions throughout its range is 31,028 animals (NMFS 2002b). Calkins et al. (1999) suggested that there are probably more sea lions at present than at any time in recorded history. The minimum population estimate for Steller sea lions in Southeast Alaska in 2005 was 20,793 (15,283 non-pups, 5,510 pups). Current population trends in Southeast Alaska are moving up, with non-pups at trend sites increasing 56 percent from 1979 to 2002, and pups increasing 148 percent (Merrick et al. 1992, Sease et al. 2001, NMFS 2006).

Steller sea lions are opportunistic predators, feeding primarily on a wide variety of fishes and cephalopods. Prey varies geographically and seasonally. Some of the more important prey species in Alaska are walleye pollock (*Theragra chalcogramma*), Atka mackerel (*Pleurogrammus monopteryguis*), Pacific herring (*Clupea harengus*), capelin (*Mallotus villosus*), Pacific sand lance (*Ammodytes hexapterus*), Pacific cod (*Gadus macrocephalus*), salmon (*Oncorhynchus* spp.), and, locally, eulachon (*Thaleichthys pacificus*).

Listed Salmon and Steelhead

Although none of the listed stocks originate from Alaskan streams, 14 of the 28 listed ESU/DPSs of salmon and steelhead could potentially be present in Alaskan waters during some period of their marine life stage (Table F-1). All of these originate from the Columbia River system or Puget Sound. Juveniles from these ESUs/DPSs move varying distances north from Washington after leaving their natal streams to rear in the rich north Pacific waters before returning to their home streams as adults (Groot and Margolis 1991, McNeil and Himsworth 1980). They may feed on prey resources originating from marine and estuarine waters of the Tongass National Forest, and could occasionally be present in inner waters of Southeast Alaska. Overall, listed stocks make up a small portion of total salmon and steelhead in waters off the coast of Alaska (NMFS 2003b). Snake River sockeye do not occur within the marine waters bounded by the Tongass National Forest in the Inside Passage, but may occur in adjacent waters near the western boundaries of the Forest. British Columbia and Washington sockeye stocks normally occur south of the Southeast Alaska sockeye stocks below the latitude of 46°N (Burgner 1991).

Any of the six listed chinook ESUs could potentially be present in marine Alaskan waters, off the outside coast to the west of the Tongass National Forest, and some may rarely be present in the marine waters of the Tongass National Forest. Columbia River chum and all ESUs of steelhead are likely present in Southeast Alaska waters only rarely (Salo 1991, NMFS 2003b). Southerly stocks of chum tend to move offshore early in their northern migration (Salo 1991). Chinook and steelhead may use nearshore marine and estuarine resources, such as prey fish, which are dependent on the Tongass National Forest.

III. Assessment of Effects on the Populations or Habitats of the Species in Relation to Proposed Actions of the Tongass Forest Plan Adjustment.

Humpback Whale

The NMFS recovery plan for the humpback whale identified six known or potential categories of human impacts to these species: hunting, entrapment and entanglement in fishing gear, collisions with ships, acoustic disturbance, habitat degradation, and competition for resources with humans. The majority (74 percent) of human-related mortalities and injuries to humpback whales investigated involved commercial fishing gear, and 38 percent of these were serious injuries or mortalities. These data were gathered from reports submitted to NMFS, Alaska Region, 2001–2005 (NMFS 2007). The estimated minimum mortality and serious injury rate incidental to U.S. commercial fisheries in Southeast Alaska is 1.4 humpback whales per year (NMFS 2007). Mortality and serious injury caused by ship strikes in Southeast Alaska occurred 1.4 times/year between 2001 and 2005.

National Forest management activities which may have an effect on whale habitats or populations generally fall into the categories of acoustic disturbance and habitat degradation. These management activities include: the development and use of log transfer facilities (LTF's) and their associated camps, the movement of log rafts from log transfer facilities to mills, and the potential development of other docks and associated facilities for mining, recreation, and other forest uses and activities. Generally, with the development and use of LTF's and other docking facilities for projects, there is an associated increase in recreational boating in the immediate vicinity during the construction and use of the facilities. Risks from hunting, entrapment and entanglement in fishing gear, ship strikes, and competition for resources with humans associated with LTF's are generally negligible. This is due to the slow speed of watercraft associated with the log transfer activity, and the lack of association between LTF's and the other risks.

Construction and operation of LTF's and other docking facilities are restricted to small, very localized areas of the marine environment. There are 116 LTF's currently on the Tongass National Forest and there is an estimated 232 acres of marine benthic disturbance associated with these existing LTF's (2 acres per LTF). However, not all LTF's are active at the same time and, in recent years, the number that are active is a small minority of the total existing. Based on the 2007 logging system and transportation analysis and modeling conducted for the 2008 Final EIS, it is estimated that a maximum of 115 new LTFs would be needed under the highest harvest alternative (Alternative 7), resulting in an estimated maximum of 230 additional acres of benthic habitat disturbance. The 2 acres of disturbance per LTF figure, assumes that logs would be placed into the water and rafted, rather than loaded onto barges as is currently required on many sales. Therefore, it is likely that future effects at each LTF would be even less than in the past.

Generally there is no reasonable potential to directly affect whales with these facilities. During the summer of 1989, there was a report of a humpback whale entangled in some cables from an inactive LTF site on the Stikine Area. To our knowledge, this is the only direct effect incident related to LTF's.

Two potential indirect effects of LTF's and other docking facilities and associated activities have been identified: 1) effects on whale prey species, and 2) disturbances of whales by boat traffic associated with LTF's.

Effects on Prey. Nemoto (1970) noted that euphausiids and gregarious fish are the primary prey of humpbacks. Thirteen species of fish and 57 species of invertebrates were identified as humpback whale prey in Southeast Alaska. Humpbacks studied in Glacier Bay and Stephens Passage-Frederick Sound were found most frequently in areas of high prey density (Wing and Krieger 1983).

Construction and operation of all LTF's and similar facilities require U.S. Army Corps of Engineers and U.S. Environmental Protection Agency permits, and State of Alaska Tidelands permits. The permitting process provides that construction and operation maintain water quality in the specific facility locations, and that marine circulation and flushing are maintained. All facilities must be in conformance with permit standards. No impacts to the marine environment which would affect whale prey species are anticipated.

Effects from Disturbance. Humpback whale response to nearby boating activity varies from no apparent response to pod dispersal, sounding, breaching, evasive underwater maneuvers, and maintaining distance (Baker and Herman 1983, Baker et. al. 1982). Disturbance by boat activity has been suggested as one of the possible causes of observed changes in whale distribution in Southeast Alaska. Direct pursuit of whales by boats, and frequent changes in boat speed and direction appear to elicit avoidance behaviors more frequently than other types of boat traffic. However, whales may readily habituate to constant and familiar noise (Norris and Reeves 1978). Whales can be commonly found in some areas of Southeast Alaska which have considerable boat traffic; however, whether they are habituated to boat traffic has not been documented, as far as we know. Adverse effects from current levels of boat traffic have not been documented, as far as we know.

Two basic types of boat activity would be associated with LTF's: log raft towing and recreational boating by workers. Log raft towing frequency would vary between camps, seasons, and years; a general average may be about once a week during the working season (U.S. Forest Service, 1989-94 Operating Period for the Ketchikan Pulp Company Long-term Sale Area). Tugs would maintain relatively constant speeds and directions during raft towing. Constant speed and direction elicit less avoidance behavior from whales than other types of boating activity. Log raft towing routes are generally well established, and adverse effects from log raft towing have not been documented.

Recreational boating activity would vary between seasons, years, and camps of different sizes. This activity would be concentrated near LTF sites, other docking facilities and camps. It is estimated that most recreational boating would occur within a few miles of the site, few trips would be made over 10 miles, and activity greater than 30 miles from a site would be negligible. This boating would involve frequent changes in speed and direction and may include some small amount of whale pursuit, if the whales are within sight of the camp or an occupied boat. The effect of such recreational activity on whales would depend on many factors such as size of the bay, depth of the waters in the bay, number of boats, individual behavior responses of the whales, etc. At the present time, there is not a quantifiable way to estimate these possible effects.

Attachment 2 outlines forest-wide standards and guidelines that have been developed for application on all Forest Service permitted or approved activities to minimize or eliminate any adverse impacts on humpback whales.

The amount of human activity in the marine environment associated with Forest management activities is only a fraction of the total amount of human activity occurring in the marine environment. Some of the other activities include: commercial fishing, sport fishing, hunting, subsistence, tourism, and mariculture.

Many of these activities are not regulated by the Forest Service. NMFS is currently proposing regulations for how close humans can approach whales. The purpose of these regulations is to reduce disturbance to whales from activities such as whale pursuing. Such regulations would reduce the indirect disturbance effects discussed above.

Steller Sea Lion

NMFS provides a summary of factors affecting the Steller sea lion populations, including:.reductions in the availability of food resources - especially pollock which is the most important prey species for sea lions; commercial harvests of sea lion pups; subsistence harvests of sea lions; harvests for public display and scientific research purposes; predation by sharks, killer whales and brown bear; disease; the inadequacy of existing regulatory mechanisms re quotas on the incidental harvesting of sea lions during commercial fishing operations; and other natural or manmade factors such as incidences of fishermen shooting adult sea lions at rookeries, haul out sites, and in the water near boats (NMFS 1990, 1993). None of these factors are regulated or fall within the jurisdiction of the Forest Service.

A primary human-caused injury and mortality factor is incidental take during commercial fisheries, though mortality by this cause is low (0.8 mortality rate for 2001–2003, or about 1/year for Pacific whiting component groundfish trawl) (NMFS 2007). Subsistence harvest is likewise low (mean annual take 2001–2005: 9), though it is aimed at both the ES and WS stocks of Steller sea lions (NMFS 2007). Illegal shooting, entanglement in non-fishery-related manmade material, and research activities also account for an additional small amount of annual mortality. The sum of these manmade mortality factors does not exceed annual potential biological removal as defined by NMFS for the ES Steller sea lions, and these can therefore be considered insignificant.

Southeast Alaska populations have not declined to the extent that other populations have. Harassment or displacement of sea lions from preferred habitats by human activities such as boating, recreation, aircraft, LTF's, log raft towing, etc., is a concern with regard to long term conservation of the sea lion in Southeast Alaska. Forest-wide standards and guidelines direct the Forest Service to prevent and/or reduce potential harassment of sea lions and other marine mammals due to activities carried out by or under the jurisdiction of the Forest Service. These Forest-wide standards and guidelines are listed in Attachment 2.

Salmon

The USDA Forest Service has no authority over the direct taking of salmon. This responsibility rests with the State of Alaska, Board of Fisheries, and ADF&G. As a land management agency, the Forest Service may indirectly influence the take of fish, both on and adjacent to the National Forest. Indirect take may occur as a result of modification of habitat or improving the opportunity to harvest salmon. Examples of the latter include the development of roads, boat launches, saltwater anchorages, or cabins; and special use permits for lodges, guides and outfitters. The following analysis considers the potential opportunity for indirect taking of the listed Snake River Sockeye, six Chinook salmon ESUs, Columbia River Chum salmon, and five steelhead DPSs believed to potentially occur in Alaskan waters (Table F-1).

Snake River Sockeye. Due to both the lack of suitable sockeye habitat in the Tongass National Forest, little or no use of prey resources potentially affected in the nearshore environment, and the lack of availability to sport and subsistence fisheries accessed through the Forest, amendment of the Tongass National Forest Land Management will not likely adversely affect the Snake River sockeye salmon.

The management of the Tongass National Forest has no direct or indirect effect on the take of the Snake River sockeye salmon. There is only a very limited relationship between the life history of these salmon and management of terrestrial habitats of the Tongass.

Snake River Chinook (All Stocks). Among the listed fish species evaluated, the six Chinook salmon ESUs are generally most likely to be found in inner waters of Southeast Alaska. Because chinook salmon are piscivores they may feed on fish which are dependent on the waters of Tongass National Forest during some stage of their lives, or these prey species may be affected by management actions. Additionally, chinook salmon are harvested in the sport and subsistence fisheries which may utilize the Tongass for saltwater access. Aquatic habitat protection measures have been designed to provide a natural range of habitat conditions in the waters of the Tongass National Forest (Riparian Forest-wide Standards and Guidelines) and have been developed to reduce or eliminate the likelihood of contribution to the degradation of freshwater habitats. Chinook prey species, such as members of the Pacific smelt family, Pacific herring, and other Pacific salmon, are not anticipated to be negatively impacted by the Tongass Forest Plan Adjustment.

The Tongass Forest Plan does not schedule any developments which measurably increase the access or opportunity to harvest Snake River chinook salmon by sport or subsistence fisheries. Additionally, it is likely that such projects that could be developed in the future, such as roads; boat launches; saltwater anchorages, cabins, special use permits for lodges, guides and outfitters,and logging camp development for the purpose of timber harvest, would have no measurable effect on the listed chinook salmon.

Columbia River Chum Salmon. Like sockeye, the effects of Tongass National Forest actions on land or in nearshore environments are not likely to affect this stock because of their rare presence in the inner marine waters of this region and small magnitude of any affects to the marine environment from any future actions.

Steelhead (All five DPSs). The nearshore resources utilized by steelhead could be affected in small regions. Again because of low probability of any of these fish being present in the inner waters, and the low chance of any adverse effects to prey resources, changes to the Tongass Forest Plan are unlikely to cause adverse effects to any of the listed steelhead DPSs. Additionally, as noted above, none of the considered actions result in any ground or nearshore marine water disturbance so the considered action will have no direct effect on these steelhead DPSs. Specific ground disturbing actions, considered in this respect, would be addressed in through agency consultation, as needed, during project specific actions.

Determination for Marine Mammals and Listed Pacific Salmon/Steelhead

Based on the analysis above, which takes into account current protection measures required by the Marine Mammal Protection Act (MMPA), ESA, and implementation of the Forest-Wide Standards and Guidelines (Attachments 2 and 3), the National Forest management activities will not likely adversely affect the humpback whale, Steller sea lion, or of the any of the ESUs or DPSs of salmonids or their habitats addressed above and listed in Table F-1.

Since the currently evaluated actions do not permit any ground disturbing activity none of the considered actions will have any direct adverse effects to any of the listed species addressed in this section. Any proposed actions indirectly resulting from the considered alternatives will be evaluated on case specific bases as to their affect to listed species and may include formal or informal consultation with NMFS at the time of project evaluation.

In addition, formal and informal consultation procedures (as directed by the ESA, as amended in 50 CFR 17.7, and FSM 2670) are used with the NMFS on all site specific projects that implement the Forest Plan. Forest-wide standards and guidelines for threatened and endangered species (Attachments 2 and 3) also direct that all projects will comply with requirements of the ESA and Forest Service Policy (FSM 2670).

Documentation of Correspondence with Other Agencies

Consultation with NMFS occurred throughout the 1997 Forest Plan Revision process and was initiated by the Forest Service in September 1987 with written letters requesting a list of threatened and endangered marine mammal and anadromous fish species for the Tongass National Forest. The evaluation of effects in the Biological Assessment indicated that populations of species under the jurisdiction of NFMS would not likely be adversely affected as a result of implementation of the decision. NMFS concurred with this determination in November 1996. They concluded Section 7 consultation by stating that consultation should be reinitiated if project plans change or new information becomes available that would change the basis of this determination,

Concurrence findings from the 1997 Forest Plan Revision are still valid for this amendment. Extensive consultation occurred throughout past revision processes of the Forest Plan; the proposed new Forest Plan is an amendment; and the above analysis and determination is consistent with the approach and findings of the 1996 Biological Assessment. The Forest Service will continue to adhere to the Forest-wide Standards and Guidelines for Threatened, Endangered, and Sensitive species, which was the basis for concurrence in the November 21, 1996 letter. Consultation will occur when site specific activities are proposed that may affect a listed species.

Forest-wide standards and guidelines in the Tongass Land Management Plan for the conservation of threatened, endangered, and proposed species (portions excerpted relevant to the Kittlitz's murrelet).

Wildlife Habitat Planning: WILD1

I. *Coordination/cooperation with other Agencies, Institutions and Partners*

A. Coordinate with the Alaska Department of Fish and Game, other state agencies, NMFS, the U.S. Fish and Wildlife Service, tribal governments, and other cooperators and partners during the planning of activities that may affect wildlife.

1. The Forest should meet at least annually with state and Federal wildlife agencies to review resource activities, present progress reports on implementation of past cooperative work or agreements, and schedule cooperative work.
2. Seek to maintain memoranda of understanding with appropriate state, Federal, and local agencies and associations.

B. Emphasize management for indigenous wildlife species and natural habitat except in cases where the Forest Service, in cooperation with the Alaska Department of Fish and Game and U.S. Fish and Wildlife Service, find desirable alternatives. Special consideration should be given to the possible adverse impacts on habitat of sensitive, threatened, and endangered species.

C. Coordinate wildlife habitat surveys, studies, plans and improvement projects with the Alaska Department of Fish and Game, U.S. Fish and Wildlife Service, NMFS, and other appropriate state, Federal, tribal, local and private agencies. Use the Sikes Act authorities for cooperative work with the state. Use agreements and other partnerships to cooperate with other partners.

D. Coordinate with the Alaska Department of Fish and Game in development of state strategic plans and population goals and objectives for wildlife species and attempt to incorporate wildlife goals and objectives into forest management.

E. Provide habitat information to the Alaska Department of Fish and Game to assist in correlating hunting seasons, permits, and bag limits to on-the-ground habitat conditions so that population and habitat objectives can be achieved.

II. *General Habitat Planning/Coordination*

A. Recognize as wildlife habitat, areas of land and water which can contribute to achieving wildlife objectives for consumptive and non-consumptive uses.

B. Provide the abundance and distribution of habitat necessary to maintain viable populations of existing native and desirable introduced species well-distributed in the planning area, i.e., the Tongass National Forest. (Consult 36 CFR 219.19 and 36 CFR 219.27.)

C. Cooperate with the State and, as appropriate, the U.S. Fish and Wildlife Service in managing vehicle, boat, and other human use (e.g. hunting and fishing seasons and bag limits) as necessary to achieve wildlife objectives, recognizing the access provisions of ANILCA. Emphasize management to reduce human disturbance in high value habitat areas and during critical periods of wildlife use.

D. Maintain a Forest program schedule which includes anticipated wildlife habitat and population inventory needs, monitoring requirements and proposed habitat improvement and maintenance projects.

E. Use forest plan management indicator species to evaluate the potential effects of proposed management activities affecting wildlife habitat (Consult Forest Service Manual 2620).

F. Develop interagency habitat capability models for any or all of the management indicators to systematically assess the impacts of proposed projects during project level analysis. Periodically review and update models to reflect the most current habitat relationships and habitat modeling technology.

G. Cooperate with the Alaska Department of Fish and Game to seek to prevent existing populations of invasive species from dispersing into Wilderness areas. Address issues regarding management, introduction, and re-introduction of wildlife species consistent with National and Regional Policy.

H. When population or habitat declines for a plant or animal species or subspecies indicates that long-term persistence is at risk, evaluate the particular species for designation as a Regional

Sensitive Species by the Regional Forester. (Consult FSM 2670 and R10 supplemental directions for Threatened, Endangered, and Sensitive Species.)

III. *Seabird Rookeries*

A. Provide for the protection and maintenance of seabird (marine bird) rookeries.

1. Locate facilities and concentrated human activities requiring Forest Service approval as far from known seabird colonies as feasible consistent with the Migratory Bird Treaty Act. The following distances are provided as general guidelines for maintaining habitats and reducing human disturbance:
    a) For aircraft flights on Forest Service permitted or approved activities, when weather ceilings permit, maintain a constant flight direction and airspeed and a minimum flight elevation of 1,500 feet (458 meters) for helicopters and fixed-winged aircraft. If at all possible, avoid flying over seabird colonies.
    b) Regulate human use to maintain a 250 meter no-disturbance distance from seabird colonies on upland habitats.
2. The availability of garbage to gulls should be eliminated by requiring Special Use Permittees to collect and dispose of garbage from their Special Use Authorizations.
3. Cooperate with state and other Federal agencies to develop sites and opportunities for the safe public viewing of these species. Maintain a public education program explaining forest management activities related to these species in cooperation with state and other Federal agencies.

IV. *Waterfowl and Shorebird Habitats*

A. Maintain or enhance wetland habitats which receive significant use by waterfowl and shorebirds. (The Tongass National Forest is a “Priority Forest’ in the national TAKING WING Strategic Plan.) “Significant” is relative, but generally relates to use of a specific area by tens or hundreds of individuals of one or more species.

1. Support the international significance of wetland habitats on the Tongass National Forest by participating in partnerships such as the North American Waterfowl Management Plan and the Western Hemisphere Shorebird Reserve Network.
2. Identify during project analysis, in cooperation with the Alaska Department of Fish and Game and the U.S. Fish and Wildlife Service, wetlands which receive significant waterfowl or shorebird use during fall/winter/spring concentrations or nesting, brood rearing or molting habitats.
3. Locate facilities and concentrated human activities requiring Forest Service approval as far from known waterfowl or shorebird concentration and nesting areas as feasible. Minimize disturbance of waterfowl by restricting, when feasible, development activities to periods when waterfowl are absent from the area.
4. During project analysis, consider the need to rehabilitate waterfowl habitat following development activities if there is no feasible alternative to the habitat disturbance. (Also see the Wetlands Forest-wide Standards & Guidelines.)
5. Maintain habitat capability in coastal wetlands and intertidal areas that are important migratory staging areas and fall/winter/spring concentration areas, and wetlands that are important nesting and brood-rearing habitats, by avoiding, where feasible, all development activities which could fill wetlands, drain wetlands, or alter water levels resulting in loss of desirable vegetation, or direct loss of habitat. (Consult the Migratory Bird Treaty Act.)
6. Minimize human disturbance of habitats during important periods of the year (nesting and brood-rearing, molting, and winter) by managing human use (such as trails, Off-Highway Vehicle use) in significant wetland areas. The following distances are provided as guidelines for reducing human disturbance:
    a) Provide a minimum distance of 330 feet (100 meters) between human activities on the ground and significant areas being used by other waterfowl.
7. Develop waterfowl habitat improvement projects in cooperation with appropriate state, Federal and local agencies, partner organizations, and individuals.
8. For Special Use Administration (non-recreational), issue only authorizations which meet the objectives of Executive Order 11990 (Protection of Wetlands). Issue permits which

serve to preserve, enhance, or aid in the management of the natural and beneficial values of wetlands.

9. Perform integrated logging system and transportation analysis to determine if other feasible routes avoiding areas where significant waterfowl use exists.
10. If the need to restrict road access is identified during project interdisciplinary review, roads will be closed either seasonally or yearlong to minimize adverse effects on waterfowl.
11. Cooperate with state and other Federal agencies to develop sites for safe-public viewing opportunities that do not adversely disturb wildlife. Maintain a public education program explaining forest management activities related to these species in cooperation with state and other Federal agencies.

B. Conduct activities to avoid or minimize disturbance to habitats within the forest, riparian, and estuarine areas which are important nesting, brooding, rearing, and molting areas, for Vancouver Canada geese, sandhill cranes, or trumpeter swans.

Threatened, Endangered, and Sensitive Wildlife Species: WILD4

Consult FSM 2670 and R10 supplemental directions for Threatened, Endangered, and Sensitive Species.

I. Threatened or Endangered Species

A. Kittlitz's Murrelet

1. Provide for the protection and maintenance of known Kittlitz's Murrelet nesting habitats.

Attachment 2

Wildlife Forest-wide Standards and Guidelines in the Tongass National Forest (portions excerpted pertaining to the conservation of marine mammals and their habitats).

WILDLIFE
Forest-wide Standards & Guidelines

Wildlife Habitat Planning: WILD1

I. *Coordination/Cooperation with Other Agencies, Institutions, and Partners*

C. Coordinate with the Alaska Department of Fish and Game, other state agencies, NMFS, the U.S. Fish and Wildlife Service, tribal governments, and other cooperators and partners during the planning of activities that may affect wildlife.
   1. The Forest should meet at least annually with state and federal wildlife agencies to review resource activities, present progress reports on implementation of past cooperative work or agreements, and schedule cooperative work.
   2. Seek to maintain memoranda of understanding with appropriate state, Federal, and local agencies and associations.

D. Emphasize management for indigenous wildlife species and natural habitat except in cases where the Forest Service, in cooperation with the Alaska Department of Fish and Game and U.S. Fish and Wildlife Service, find desirable alternatives. Special consideration should be given to the possible adverse impacts on habitat of sensitive, threatened, and endangered species.

E. Coordinate wildlife habitat surveys, studies, plans and improvement projects with the Alaska Department of Fish and Game, U.S. Fish and Wildlife Service, NMFS, and other appropriate state, federal, tribal, local and private agencies. Use the Sikes Act authorities for cooperative work with the state. Use agreements and other partnerships to cooperate with other partners.

F. Coordinate with the Alaska Department of Fish and Game in development of state strategic plans and population goals and objectives for wildlife species and attempt to incorporate wildlife goals and objectives into forest management.

G. Provide habitat information to the Alaska Department of Fish and Game to assist in correlating hunting seasons, permits, and bag limits to on-the-ground habitat conditions so that population and habitat objectives can be achieved.

II. *General Habitat Planning/Coordination*

A. Recognize as wildlife habitat, areas of land and water that can contribute to achieving wildlife objectives for consumptive and non-consumptive uses.

B. Provide the abundance and distribution of habitat necessary to maintain viable populations of existing native and desirable introduced species well-distributed in the planning area, i.e., the Tongass National Forest. (Consult 36 CFR 219.19 and 36 CFR 219.27.)

C. Cooperate with the State and, as appropriate, the U.S. Fish and Wildlife Service in managing vehicle, boat, and other human use (e.g. hunting and fishing seasons and bag limits) as necessary to achieve wildlife objectives, recognizing the access provisions of ANILCA. Emphasize management to reduce human disturbance in high value habitat areas and during critical periods of wildlife use.

D. Maintain a Forest program schedule that includes anticipated wildlife habitat and population inventory needs, monitoring requirements and proposed habitat improvement and maintenance projects.

E. Use forest plan management indicator species to evaluate the potential effects of proposed management activities affecting wildlife habitat. (Consult Forest Service Manual 2620.)

F. Develop interagency habitat capability models for any or all of the management indicators to systematically assess the impacts of proposed projects during project level analysis. Periodically review and update models to reflect the most current habitat relationships and habitat modeling technology.

G. Cooperate with the Alaska Department of Fish and Game to seek to prevent existing populations of invasive species from dispersing into Wilderness areas. Address issues regarding management, introduction, and re-introduction of wildlife species consistent with National and Regional Policy.

H. When population or habitat declines for a plant or animal species or subspecies indicates that long-term persistence is at risk, evaluate the particular species for designation as a Regional Sensitive Species by the Regional Forester. (Consult FSM 2670 and R10 supplemental directions for Threatened, Endangered, and Sensitive Species.)

III. Marine Mammal Habitats

H. Provide for the protection and maintenance of harbor seal, Steller sea lion and sea otter habitats.

1. Ensure that Forest Service permitted or approved activities are conducted in a manner consistent with the MMPA, the ESA, and NMFS guidelines for approaching seals and sea lions. Consult with the appropriate agency for identification of critical timing events, such as molting, parturition, etc., and recommended distances to avoid disturbances. "Taking" of marine mammals is prohibited; "taking" includes harassment (adverse disturbance), pursuit, or attempting any such activity.
2. Locate Forest Service authorized and approved facilities and concentrated human activities as far from known marine mammal haul outs, rookeries and known concentration areas as feasible to meet the Alaska Coastal Management Program (ACMP) consistency requirements and MMPA. The following distances are provided as general guidelines for maintaining habitats and reducing human disturbance:
   a) Locate camps, Log Transfer Facilities, campgrounds and other developments (where allowed by the Land Use Designation) 1 mile from known haul outs, and farther if the development is large.
   b) Forest Service permitted or approved activities will not intentionally approach within 100 yards, or otherwise intentionally disturb or displace any hauled-out marine mammal.
   c) Dispose of waste oil and fuels off-site as regulated by the Alaska Department of Environmental Conservation.
3. Cooperate with the state and other federal agencies to develop sites and opportunities for the safe viewing and observation of marine mammals by the public. Maintain a public education program explaining forest management activities related to marine mammals in cooperation with state and other Federal agencies.

Threatened, Endangered, and Sensitive Wildlife Species: WILD4

Consult FSM 2670 and R10 supplemental directions for Threatened, Endangered, and Sensitive Species.

I. Threatened or Endangered Species

A. Steller Sea Lion

1. Protect Steller sea lion habitats.
2. Ensure that Forest Service funded, permitted or authorized activities are conducted in a manner consistent with the requirements, consultations, or advice received from the appropriate regulatory agencies for the MMPA, the ESA, and NMFS guidelines for approaching seals and sea lions. "Taking" of sea lions is prohibited; "taking" includes harassing or pursuing or attempting any such activity.
3. Locate facilities, camps, Log Transfer Facilities, campgrounds and other developments 1 mile from known haulouts, and, farther away, if the development is large.
4. Cooperate with state and other federal agencies to develop sites and opportunities for the safe viewing and observation of sea lions by the public. Maintain a public education program explaining forest management activities related to sea lions in cooperation with state and other federal agencies.

B. Humpback Whale

1. Provide for the protection and maintenance of whale habitats.
2. Ensure that Forest Service permitted or approved activities are conducted in a manner consistent with the MMPA, the ESA, and NMFS regulations for approaching whales, dolphins, and porpoise. "Taking" of whales is prohibited; "taking" includes harassing or pursuing or attempting any such activity.

Attachment 3

Forest-wide standards and guidelines in the Tongass Forest Plan for the conservation of threatened, endangered, and proposed fish species. These conservation measures serve to protect important habitat that may be used for listed Pacific salmon and steelhead.

FISH
Forest-wide Standards & Guidelines

Fish Habitat Inventory and Monitoring: FISH1

I. *Fish Habitat Inventory*
   - A. Maintain the channel type and stream class (see Glossary) based inventory of all Forest streams.
     - 1. Maintain and update the stream inventory (and GIS mapping) during site-specific project planning and analysis.
       - a) Consult publication *R10-TP-26, A Channel type Users Guide for the Tongass National Forest, Southeast Alaska* (as revised), for descriptions of the channel types.
       - b) Consult the Aquatic Habitat Management Handbook FSH 2090.21 for descriptions of Region 10, stream survey methodologies.
   - B. Maintain the inventory of Forest streams and watersheds for fish enhancement opportunities.
   - C. Maintain, and further develop as necessary, the fish-habitat-objectives database used to measure changes in the natural range and frequency of aquatic habitat conditions. (See FISH 112,IV(B) and Appendix B.)

Fish Habitat Planning: FISH2

I. *Fish Habitat and Channel Processes*
   - A. Recognize watershed function and channel processes when planning for the protection, restoration or enhancement of fish habitat. (Consult Riparian Forest-wide Standards and Guidelines RIP2 and Soil and Water Forest-wide Standards and Guidelines S&W112.)
     - 1. Consider the effects of upstream and upslope activities during site-specific planning.
     - 2. Consider the condition of upstream and upslope areas during site-specific planning.
     - 3. Consider topics such as erosion processes, watershed hydrology, vegetation, stream channel morphology, water quality, wilderness designation, recommendations for inclusion into the Wild and Scenic River System, species and habitats, and human uses, during analyses.

II. *Channel Classification and Process Groups*
   - A. Use channel type inventories to categorize stream reaches into channel process groups. Use channel types and process groups to plan management activities affecting fish and fish habitat along all lakes and streams. Process groups and the channel types included in each process group are shown in Appendix D, and in publication R10-TP-26, A Channel type Users Guide for the Tongass National Forest, Southeast Alaska. These groups may be redefined as more information about channel types becomes available.
     - 1. Map and field-verify streams, lakes and estuaries by channel type and stream class for project planning and implementation.

III. *Fish Stream Classification* ***(reference FSH 2090.21 (2001) Chapter 10, Section 12)***
   - A. Determine fish/water quality value class of all streams in the affected area prior to or during site-specific project planning (also see Riparian Standards and Guidelines).
   - B. Use the following classification system across the Forest.
     - 1. **Class I:** Streams and lakes with anadromous or adfluvial fish or fish habitat; or high quality resident fish waters or habitat above fish migration barriers known to provide reasonable enhancement opportunities for anadromous fish.
     - 2. **Class II:** Streams and lakes with resident fish or fish habitat—generally steep channels 6 to 25 percent or higher gradient—where no anadromous fish occur, and otherwise do not meet Class I criteria.
     - 3. **Class III**: Perennial and intermittent streams with no fish populations but which have sufficient flow, or transport sufficient sediment and debris, to have an immediate influence

on downstream water quality or fish habitat capability. For streams less than 30 percent gradient special care is needed to determine if resident fish are present.

A stream segment is designated Class III if the following conditions are met **for the majority of its length:** Bankfull stream width greater than 1.5 meters (5 feet) **and** channel incision (or entrenchment) greater than 5 meters (15 feet).

Streams that do not meet both the width and incision criteria may be classified as class III streams based on a professional interpretation of stream characteristics for the stream segment being assessed. The following characteristics **could** indicate a class III stream:

a. Steep side-slopes containing mobile fine sediments, sand deposits, or deep soils that can provide an abundant source area for sedimentation.

b. Very steep gradient channels (greater than 35 percent slope).

c. Recently transported bedload or woody debris wedges (especially if deposited outside high water mark).

d. High water indicators (scour lines, drift lines etc) that greatly exceed observed wetted stream width.

e. Large sediment deposits stored amongst debris that could be readily transported if debris shifts.

4. **Class IV**: Other intermittent, ephemeral, and small perennial channels with insufficient flow or sediment transport capacity to directly influence downstream water quality or fish habitat capability. Class IV streams **do not** meet the criteria used to define Class I, II or III streams. Class IV streams must have bankfull width of at least 0.3 meters (1 foot) over the majority of the stream segment. For perennial streams, with average channel gradients less than 30 percent, special care is needed to determine if resident fish are present (resident fish presence dictates a Class II designation).

5. **Non-streams**: Rills and other watercourses, generally intermittent and less than 1 foot in width, little or no incision into the surrounding hillslope, and with little or no evidence of channel scour (Note: these micro-drainage features are not mapped in GIS hydrography layers).

IV. Objectives/Guidelines for Management Affecting Fish Habitat

A. Maintain or restore the natural range and frequency of aquatic habitat conditions on the Tongass National Forest to sustain the diversity and production of fish and other freshwater organisms.

B. Use (and update) baseline fish habitat objectives as a reference to evaluate the relative health or condition of riparian and aquatic habitat. Use baseline fish habitat objectives, listed below (and others as developed), (AFHA, 1995, Bryant et. al. 2004, Woodsmith et. al. 2005) to characterize the natural range of habitat conditions by channel types and process groups. Specific measurement protocols are described in the Alaska Region Aquatic Management Handbook (FSH 2090.21 – 2001-1)

1. Width-to-depth ratio. Relationship between bankfull width and average bankfull depth, expressed as average bankfull width / average bankfull depth.
2. Large woody debris. Frequency of qualifying large wood pieces per kilometer of stream.
3. Total key pieces of large woody debris. The frequency of large, structurally integral pieces of wood scaled to channel size per kilometer of stream.
4. Pools per Kilometer. Frequency of qualifying pools per kilometer of stream.
5. Pool spacing. Frequency of qualifying pools per unit area of channel, length of channel surveyed / average channel bed width / number of pools.

6. Residual pool depth per channel bed width. Residual pool depth scaled to channel size, residual pool depth / average channel bed-width.
7. Median particle size.
8. Pool length per meter. Total qualifying pool length divided by length of survey.
9. Pool size (relative depth). Average residual pool depth / average bankfull depth.
10. Relative submergence. Expressed as average bankfull depth.

C. Maintain or restore stream banks and stream channel processes.
   1. Stream Class I, and Class II streams that flow directly into Class I streams. Maintain, restore or improve anadromous, adfluvial, and high value resident fish habitat capability by providing natural or improved cover/pool ratio, pool-riffle sequences, and habitat features, such as stable large woody debris. Design management activities to maintain stream bank, channel and flood plain integrity.
   2. Other Stream Class II: Maintain or restore habitat capability for resident fish populations by providing natural or improved cover/pool ratio, pool-riffle sequences, and habitat features, such as stable Large Woody Debris. Design management activities to maintain stream bank, channel, and flood plain integrity. Avoid impacts to downstream Class I streams.
   3. Stream Class III: Design management activities to maintain or restore stream bank, channel, and flood plain integrity. Avoid impacts to downstream Class I and Class II streams.

D. Maintain or restore natural and beneficial quantities of Large Woody Debris (LWD) over the short and long-term.
   1. Stream Class I, and Class II streams that flow directly into Class I streams. Maintain or restore anadromous, adfluvial, and high value resident fish habitat capability by providing for natural and beneficial volumes of LWD for rearing, stream energy dissipation, and sources of organic matter to the stream ecosystem. Use biological and physical characteristics of the stream to determine size classes and distribution of LWD. Limit navigational clearing of large wood to the minimum necessary for safety.
   2. Other Stream Class II: Maintain or restore habitat capability for resident fish populations by providing LWD, and by designing for future sources of LWD at volumes determined by channel type biological and physical characteristics.
   3. Stream Class III: Maintain or restore LWD in channels and banks to prevent changes in natural stream bank and stream channel processes.

E. Maintain or restore water quality to provide for fish production.
   1. *Stream Classes I, II, and III*: Prevent adverse effects to rearing and spawning habitat. Maintain or restore anadromous, adfluvial, and high value resident fish habitat capability. Maintain or restore capability for other resident fish populations to the extent feasible. Assure no chronic sediment input following soil-disturbing activities. Prevent adverse impacts to fish habitat downstream by minimizing siltation.
   2. Implement applicable Best Management Practices. (FHS 2509.22).

F. Maintain or restore optimum water temperatures for salmonids, considering both winter and summer habitat requirements, climate, and natural watershed characteristics.
   1. Stream Class I, and Class II streams that flow directly into Class I streams. Maintain or restore optimum salmonid summer stream temperatures at between 50 and 68°F or at natural levels.
   2. Other Stream Class II: Maintain water temperatures below 68°F, or at natural levels, to maintain or restore habitat capability for resident fish populations. Manage watersheds and riparian streamsides to maintain water temperature standards and guidelines for downstream Class I streams.
   3. Stream Class III: Manage watersheds and riparian streamsides to maintain water temperature standards and guidelines for downstream Class I and II streams.

G. Maintain, restore or improve, where feasible (see glossary), stream conditions that support the migration or other movement of aquatic organisms inhabiting a waterbody.
   1. If a stream crossing cannot be avoided then the best solution for aquatic organism passage is generally to maintain the natural stream form and processes from the inlet, through the crossing, and into the downstream channel. Bridges, open bottom culverts and stream simulated culverts designed and installed to applicable BMPs (Soil and Water

Conservation Handbook , FSH 2509.22) and design standards (Aquatic Habitat Management Handbook, FSH 2090.21) to best meet this objective.

2. Some stream conditions, engineering constraints or cost may make it desirable to install culverts that use a variety of weir/baffles or roughened channel to provide for passage. These hydraulically designed culverts rely on matching culvert hydraulic conditions at a specified design flow to the swimming performance of a specified design fish (Aquatic Habitat Management Handbook, FSH 2090.21).
3. Stream crossing structures requiring aquatic organism passage will be designed to current standards by qualified professionals.
4. Consult applicable Best Management Practices (see FSH 2509.22).
5. Consult and improve the inventory of identified fish stream crossings.
6. As per Memoranda of Understanding between the Forest Service and the Alaska Department of Natural Resources (ADNR, 2004), and the Alaska Department of Environmental Conservation (ADEC, 1992), culvert installation, stream alignment or diversions; dams; low-water crossings; and construction, placement, deposition, or removal of any material or structure below ordinary high water all require State concurrence.
7. Overall, the intent is to not disrupt the migration or movement of aquatic organisms, but occasionally it is not feasible to protect some sections of habitat and movement will be restricted. In determining feasibility consider the following:
   a) Presence of known sensitive, isolated or unique fish populations.
   b) Extent and quality of available habitat and how it is affected by the location of the stream crossing.
   c) The cumulative impacts of restricting fish passage at multiple sites in the same watershed.
   d) The upstream and downstream linkages between the anadromous and resident life strategies of the same species.
   e) Advice from the Alaska Department of Fish and Game and the Alaska Department of Natural Resources.
   f) The length of time that a stream structure will restrict movement.
   g) The cost of providing ideal passage conditions compared to less than ideal conditions.
   h) Availability of suitable, cost effective compensatory mitigation projects.
8. The discharge of dredge or fill material from normal silviculture activities such as timber harvest is exempt from Clean Water Act Section 404 permitting requirements in waters of the United States (404(f)(1)(A). Forest roads qualify for this exemption only if they are constructed and maintained in accordance with BMP's specified in 33CFR 323.4(a). These BMPs have been incorporated into BMP 12.5 in the Alaska Region's BMP Handbook (FSH 2509.22)

V. Management Indicators

A. Use forest plan management indicators to evaluate the potential effects of proposed project management activities affecting fish habitat.

VI. Management Activities

A. Maintain a fish program schedule which includes anticipated inventory needs, proposed habitat improvement and maintenance projects, and monitoring requirements.

VII. Coordination

A. Coordinate activities that affect fish resources with other Forest disciplines through the Interdisciplinary Team process, and with state, other Federal, and local agencies and groups.
   1. Develop and maintain Memoranda of Understanding/Agreements with appropriate state, Federal, and local agencies and aquaculture associations.
   2. Coordinate with the state and federal agencies, and the Pacific Northwest Research Station, to maintain a continuous program for research, monitoring, and assessment of impacts of land-use activities on fish habitat.

B. Consider the influence of proposed management activities on fishing use patterns.

C. Consider effects of Off-Highway Vehicle (OHV) travel and road closures on fish habitat and populations.

VIII. Projects

A. Use the following priority for fish habitat project work: mitigation for unplanned impacts, rehabilitation/restoration, enhancement. For both mitigation and rehabilitation, consider alternatives for cost efficiency of performing off-site enhancement (enhancement of a different area than where the impact actually occurs).
   1. Location of off-site enhancement shall be governed by the following priorities:
      a) First priority: same stream reach (same species)
      b) Second priority: same stream (same species)
      c) Third priority: same watershed (same species)
      d) Fourth priority: same anadromous fish harvest area (same species)
      e) Fifth priority: differing species, using above priority order

B. Enhance fish habitat to meet the objectives identified in this plan. Opportunities may include, but are not limited to: instream enhancement, lake fertilization, cooperative bio-enhancement (e.g., stocking), incubation boxes, and fishway construction.
   1. Use the Cooperative Fisheries Planning process (Consult ANILCA Section 507) and/or other cooperative agreements for developing priorities for the enhancement of fish resources.
   2. Determine habitat capability on streams and lakes identified for enhancement in the Cooperative Fisheries Planning process prior to construction of fish projects.
   3. Update the fish habitat enhancement list (Cooperative Fisheries Planning process) periodically.

C. Recognize bio-enhancement (e.g., stocking of juveniles, use of egg incubation boxes, transferring of adult fish to seed stream systems) as part of the fish improvement project costs when appropriate. Cooperate/coordinate with fish agencies and aquaculture associations to facilitate bio-enhancement.

D. Fishpass projects abide by the standards and best practices for colonization projects included in the Comprehensive Salmon Enhancement Plan for Southeast Alaska, Phase III.

E. Coordinate new projects to enhance the use of National Forest System lands with the recreation program managers.

Fish Habitat Improvement: FISH3

I. Planning

A. Improve or restore fish habitat to work toward the habitat objectives of the Forest Plan.

B. Construct projects using the most cost-efficient methods, while achieving desired results consistent with the Land Use Designation.

C. During project planning consider the need to monitor the accomplishment of project objectives. Need shall be governed by the type of project, with high interest/high investment projects being monitored more intensively.
   1. Where needed, develop cooperative agreements with fish/aquaculture agencies and other groups to assess the effectiveness of Forest Service habitat improvement.

II. Construction Coordination

A. Coordinate all fish habitat improvement using an interdisciplinary process.

B. Coordinate habitat improvement projects with the Alaska Department of Fish and Game and other appropriate agencies and groups.

III. Monitoring

A. Conduct monitoring of fish improvement projects to insure their continued function at the design level of operation.

B. Monitor fish production on a representative sample of improvement projects to evaluate effectiveness of individual projects, categories of similar projects, and the effectiveness of the overall improvement program.

Fish Habitat Maintenance: FISH4

I. Maintenance

A. Provide for the maintenance of fish habitat enhancements.
   1. Fund maintenance of existing projects prior to the construction of new ones.
   2. Include funding for maintenance in the planning and budgeting for all projects.

3. Maintain improvements to assure that investment objectives are met.
4. When maintenance and operation of an improvement become inefficient , reconstruct or remove the improvement.
5. If an improvement becomes inoperable, reconstruct or remove the improvement.

B. Develop a written maintenance responsibilities agreement with project cooperators prior to project construction.

Threatened, Endangered, and Sensitive Fish Species: FISH5

Consult FSM 2670 and R10 supplemental directions for Threatened, Endangered, and Sensitive Species.

I. Threatened or Endangered Species

A. There are currently no Threatened or Endangered fish species on the Tongass National Forest.

II. Sensitive Fish Species

A. Island King Salmon
1. Provide for the protection and maintenance of runs of king salmon that naturally occur on islands including the runs in King Salmon and Wheeler creeks on Admiralty Island.
2. Coordinate with the Alaska Department of Fish and Game and NMFS on commercial, sport and subsistence fish use, hatchery egg take programs, and other activities affecting the viability of king salmon runs in order to conserve these unique populations.
3. Avoid the placement of facilities or issuing permits for activities near these streams that would increase harvest pressure on these king salmon runs.

B. Northern Pike
1. Provide for the protection and maintenance of northern pike found in the Pike Lakes on the Yakutat Forelands. This population of northern pike is unique to Southeast Alaska.
2. Avoid the placement of facilities near the Pike Lakes which would increase harvest pressure to the point where the viability of these species is affected.
3. Coordinate with the Alaska Department of Fish and Game on any activities that would affect the viability of the northern pike.

C. Fish Creek Chum Salmon
1. Provide for the protection and maintenance of chum salmon in Fish Creek near Hyder. This population of chum salmon is characterized by their extraordinary large size.
2. Coordinate with the Alaska Department of Fish and Game and NMFS on commercial, sport and subsistence fish use, hatchery egg take programs, and other activities affecting the viability of the chum salmon runs in Fish Creek in order to preserve these populations.
3. Provide for habitat improvement and maintenance to maintain the viability of this run of salmon, as necessary.

Appendix G

Timber Demand and Supply on the Tongass National Forest

Susan J. Alexander, PhD
Regional Economist, US Forest Service Alaska Region
December 7, 2007

Summary

Since 1990, when the Tongass Timber Reform Act (P.L. 101-626) required the Tongass National Forest to take economics into account in planning timber sale programs, a number of demand studies have been published by the US Forest Service Pacific Northwest Research Station, assessing derived demand for Alaska wood products. Information from these demand assessments is incorporated into short-term timber sale planning through a supply model, and into long-term planning through the Forest Plan process. This appendix supports text in the Forest Plan amendment EIS, provides additional information about the Brackley et al. (2006a) demand estimates, and outlines how the Brackley et al. demand projections are incorporated into annual timber sale offer target calculations on the Tongass National Forest.

Introduction

Section 101 of the 1990 Tongass Timber Reform Act (TTRA) states that:

> Subject to appropriations, other applicable law, and the requirements of the National Forest Management Act (P.L. 94-588); except as provided in subsection 9d) of this section, the Secretary shall, to the extent consistent with providing for the multiple use and sustained yield of all renewable forest resources, seek to provide a supply of timber from the Tongass National Forest which (1) meets the annual market demand for timber from such forest and (2) meets the market demand from such forest for each planning cycle.

The 1997 Record of Decision for the Tongass Land and Resources Management Plan Revision committed the US Forest Service to develop procedures to insure that annual timber sale offerings would be consistent with implementing the "seek to meet market demand" language of the TTRA. Those procedures were completed in 2000, and have become known as the "Morse methodology" after their author. These procedures are based on the premise that:

- Forest products markets are volatile, especially in the short run.
- Timber purchasers in Southeast Alaska have few alternative suppliers of timber if they cannot obtain it from the Tongass National Forest. Oversupplying this market has relatively few adverse economic effects; undersupplying it can have much greater negative economic consequences.
- It takes years to prepare national forest timber for sale, including completion of environmental impact statements.
- It is difficult to estimate demand for timber from the Tongass, even a year or two in advance.
- Industry must be able to respond to rapidly changing market conditions in order to remain competitive.

Accordingly, the Morse methodology establishes a system that seeks to build and maintain sufficient volume of timber under contract (timber purchased but not yet harvested, the primary indicator of timber inventory available to the industry) to allow the industry to react promptly to market fluctuations. Industry actions such as annual harvest levels are monitored and timber program targets are developed by estimating the amount of timber needed to replace volume harvested from year to year. The Morse methodology is self-correcting, because if harvest levels drop below expectations, future timber sale offerings will also be reduced to levels needed to maintain the target level of volume under contract. Conversely, if harvest levels rise unexpectedly, future timber sale targets will also increase sufficiently to ensure that the inventory of volume under contract is not exhausted. By dealing with uncertainty in a flexible, science-based fashion, the Morse methodology is an example of adaptive management. The Forest Service intended the Morse methodology to be the means by which the agency complies year-by-year with the annual demand portion of the TTRA “seek to meet” requirement. Similarly, the agency intended to comply with the requirement to seek to meet demand “for each planning cycle” through a series of annual applications of the Morse methodology.

The US Forest Service Pacific Northwest Research Station has published several studies conducted in support of Tongass Land Management planning that estimate derived demand for timber in Southeast Alaska, including Brooks and Haynes (1997) and Brackley et al. (2006a). The procedures developed by Morse (2000) to estimate the timber offer target (supply) incorporate the demand numbers from the PNW studies as an input into a spreadsheet. The PNW derived demand projections are trend projections and should be interpreted as five-year averages. The Morse methodology relates these derived demand projections into an annual calculation of timber sale offer levels.

The procedures developed by Morse (2000) to estimate the annual sale offering targets from the Tongass National Forest address the uncertainty associated with forecasting market conditions, considering the continuing transformation of the timber industry and the inability of the Forest Service to respond quickly to market fluctuations due to the time it takes to prepare timber for sale. The basic approach developed is to allow the industry to accumulate an adequate volume under contract (a measure of inventory), then monitor industry behavior and adjust timber program levels to keep pace with the harvest activity. Key economic indicators and stumpage market conditions are monitored. The method underwent rigorous technical and public review before it was implemented. Since the method was initially developed by Morse (2000), inputs to the model have been adjusted to reflect new understandings and information, such as share of raw material provided by the Tongass National Forest to local processors, the amount of time between purchase and harvest of a timber sale, and mill capacity. In this way, the approach has allowed for adaptations to current situations.

Morse (2000) outlined monitoring goals, with some specific criteria for action. An update of the timber demand assessment by Brooks and Haynes (1997) was requested from the US Forest Service Pacific Northwest Research Station, because sales to domestic markets now account for more than 35 percent of lumber products in Southeast Alaska. The PNW Research Station published new demand projections (Brackley et al. 2006a) with some changes in how alternative scenarios were presented and how timber volume was characterized. The new projections contain four scenarios, as opposed to the three in Brooks and Haynes (1997), and the timber volume in the Brackley et al. (2006a) demand projections is demand for decked logs (stacked logs at processing facilities) plus a portion of cedar log shipments out of Alaska.in scenarios 1 and 2. The authors acknowledge that pulpwood grade material may be left in the woods, but they do not include that volume in these two projections. In the case of scenario 3 and 4, the derived demand estimates include pulpwood quality material that is assumed to be left in the woods under scenarios 1 and 2, decked logs at processing facilities, and cedar log shipments out of Alaska. The new projections do not require a change in the basic methodology for timber offer calculations in the procedure outlined in Morse (2000).

During the 1990s, competition with production in other regions and market conditions led to the closure of Southeast Alaska’s two pulp mills and numerous closures of sawmill facilities. The twelve remaining active mills operated at about 13 percent of their estimated capacity in 2005. The Tongass National Forest contributed about 65 percent of wood sawn by local mills from 2002 to 2006 (Kilborn et al. 2004; Brackley et al. 2006b; data from mill surveys conducted by Dan Parrent of Juneau Economic Development and on file with the Regional Economist, US Forest Service Alaska Region). Although about one-third of sawn wood has come from State of Alaska lands, State lands comprise a relatively small percentage of Southeast Alaska forest lands, and State lands cannot indefinitely supply such a high proportion of the needs of remaining Southeast Alaska sawmills. A very small proportion (less than one percent) has come from private lands in the past five years. The primary destination for material sawn in Southeast Alaska is currently other states within the U.S. Brackley and Haynes (in press) conclude that many of the lumber and wood products markets Alaska mils compete in are higher-end markets in which foreign and domestic prices have become fairly similar, through market arbitrage. Haynes at al. (2007) found that since 1994, the value of U.S. forest product exports has been in gradual decline while the value of imports has steadily increased. Hansen (2006) states that U.S. companies have historically jumped into the export market when the domestic market is down, and shifted back to the U.S. market when the domestic market improves. In recent years, the U.S. domestic market has been very attractive with high housing starts and strong prices in many forest product categories. Haynes et al. (2007) state that U.S. demand for forest products is varied and large, averaging 71.4 cubic feet per person per year. This per capita consumption of wood products in the U.S. has been relatively constant for 50 years. Total U.S. forest products consumption is projected to continue to rise. U.S. imports of wood products are projected to rise at a somewhat faster rate than domestic wood supply. U.S. import dependence is projected to reach more than one-quarter of the total of all wood products consumed and exported in the US by 2010. Economic globalization throughout wood products manufacturing is contributing to a global realignment of growth in raw material demands. In addition to this realignment of where manufacturing takes place, sheer population growth will drive increases in wood products demand both in the US and world-wide. Ince et al. (in press) state that countries such as China are emerging in the 21st century as growth leaders in wood raw material and industrial wood product demand.

Brackley and Haynes (in press) examined trade information and literature on Chinese wood products markets, and concluded that one of the most significant events of the 21st century has been the emergence of China and other Asian nations into world markets. Although China and other undeveloped Asian nations will probably have a minor impact on demand for softwood products produced in southeast Alaska in the next 5 years, in the longer term there will be direct and indirect impacts “that will provide markets for any level of production the forest products industry in southeast Alaska may attain” (Brackley and Haynes, in press; 26).

In 2007, the US Forest Service in Alaska approved a new policy under which timber purchasers may ship to the lower 48 states unprocessed certain small-diameter and low-quality logs harvested from the Tongass, up to 50 percent of the volume harvested on each sale. This interstate shipments policy places purchasers of Tongass National Forest timber in a similar position as their counterparts in the Lower 48, where there is no restriction on interstate shipments of timber harvested from National Forest System lands. While it is still early in the implementation of the new policy, full implementation of it over the next year or two could make Alaska forest products producers more competitive with their counterparts in the Lower 48 States. That may allow Alaska producers to increase their share of domestic forest products markets, which would stimulate demand for timber from the Tongass without the construction of new processing facilities in Southeast Alaska. In addition, a new veneer mill has opened in Ketchikan that uses low-grade sawtimber.

On the supply side, the cost of preparing stumpage for sale and delivering it to mills has increased, due to decreased size of sales, increased fuel costs, legal and procedural challenges to federal timber sales, and more constraints on harvest activity in the interest of resource protection. The uncertainty surrounding Tongass National Forest sale quantities has increased the risk faced by potential purchasers and investors in local processing capacity.

Demand Estimation

The method to project timber harvests and output in Alaska followed by Brackley et al. (2006a) is essentially the same as that employed in previous estimates of Alaska timber demand by Haynes and Brooks (1990), Brooks and Haynes (1990), Brooks and Haynes (1994), and Brooks and Haynes (1997). Derived demand is determined by converting demand in all markets, foreign and domestic, to the timber volume that is required to produce the defined products utilized by the market. In the model, ratios are used to assign a portion of the total global demand to producing regions. Brackley et al. (2006a) then estimate the Alaska forest products output, by product, required to meet projected demand, and calculate the raw material requirements necessary to support this production, using explicit product recovery and conversion factors. The total raw material requirement (the total derived demand for timber) is a combined projection of timber harvest from private ownership, from National Forests, and from non-National Forest public owners. The projected National Forest timber demand is the quantity of timber required to satisfy projected derived demand given harvest by other owners, and given explicit assumptions about markets and implicit assumptions about prices (described below). The study analyzes trends over a historical period of about 40 years (1965 to 2004) as a basis for a projection of 20 years (2005 to 2025) in three key parameters:

1. The level of forest products imports in Pacific Rim nations. According to Brackley and Haynes (in press), the PNW demand studies define the Pacific Rim as the major producing areas of the three contiguous Pacific coast states (California, Oregon, and Washington), British Columbia, Alaska, the Russian Far East, and major consuming regions of Japan, Korea, Taiwan, and China (Haynes and Brooks 1990). Based on other research regarding these markets, the Brackley et al. demand study projects that Pacific Rim imports of sawn wood products will increase over the next 20 years.
2. The share of those markets that will be supplied by North American forest products producers, which the study projects will remain constant.
3. The share of North American exports to the Pacific Rim that will come from Alaska. The analysis examines four alternative assumptions regarding future trends of the Alaskan share of North American exports to the Pacific Rim.

Brackley et al. (2006a) assembled historic data that describe relevant components of the Alaska forest sector and calculated possible future wood needs by using an analysis of trends in factors that influence harvests. They also used assessments of current markets from other analysts. Data from the historic period of 1965 to 2004 were used as a basis for the projection of the future (2005 to 2025), to avoid emphasis on short-term cycles. Trends in consumption (for example, of sawn wood in Japan), and trends in production, represented by shipments (for example, of lumber to all destinations) make up the basic structure of the model. The authors recognized that the US is a net importer of timber. A mill in Alaska has the option to ship products to traditional export markets, emerging new markets, or the lower 48 states. Demand for wood products is global in nature and increasing amounts of wood products are being imported into the United States. The primary determinate of where products will be shipped is price. There are many high-value products (such as large timbers for architectural designed buildings, and shop grades of lumber) that are now being shipped to the lower 48 from Alaska.

The demand model calculates the quantity of National Forest timber needed by mills as a residual necessary to balance the model. In other words, Brackley et al. (2006a) estimated the roundwood equivalent of all material used to produce products from Alaska, and subtracted estimated future volume harvested from other landowners to derive National Forest roundwood needs (the “residual”). The results in Brackley et al. (2006a) reflect decked roundwood volume (stacks of unprocessed logs) at processing facilities.

Stumpage price projections in the PNW demand studies are linked to price series used and projected in the Resource Panning Act assessments (such as Haynes et al. 2007). Stumpage prices in Alaska are estimated as a function of prices in western Washington and Oregon. Alaska markets directly interact with producers and consumers in other US regions through this price relationship. Brackley and Haynes (in press) explain that “market arbitrage is used to understand parity among prices in spatially distinct markets where there is the opportunity for open exchange (trade). Market arbitrage is a powerful force that keeps prices of different species, grades, and locations within some fixed proportion to each other. Abstracting from transportation and transactions costs, for example, prices of one species and grade will not exceed prices for other species of a similar grade in the long run because of possibilities of substitution.” Tying price in Alaska to price in the Pacific Northwest is how market arbitrage is included implicitly in the demand assessment. The mix of products that go into end markets from Alaska are, on average, higher quality and more valuable than the average lumber markets in Washington, Oregon, and British Columbia (Brackley and Haynes in press). The type of lumber products in the demand projections reflects this higher value by the type of markets they compete in. Although price is not explicit in the PNW demand studies, it is reflected through this mix of generally higher value products that go into various end markets, and by the assumption that Alaska price is a function of US price.

Alaska is one of the last places in western North America that produces products from slow-grown large old trees. Old-growth trees and some younger trees in Alaska have special high-quality strength and appearance characteristics. Wood products manufactured in Alaska generally go into high-end markets, such as window casings and door moldings. These markets are arbitraged throughout the Pacific Rim, meaning that prices for these products are similar regardless of what market it goes into—domestic or foreign. Brackley and Haynes (in press) illustrate how Alaska producers have shifted in and out of domestic markets. Brackley et al. (2006a) accounted for this market arbitrage by assuming export products would be synonymous with high-value products that could be sold in domestic or foreign markets based on price.

Brackley et al. (2006a) used information about US exports to Japan, and Japanese import data, as a benchmark for the historic data, as such exports represented, until very recently, the vast majority of sawn wood production from Southeast Alaska. Data about domestic end markets for sawn wood production from Southeast Alaska have been available since about 2000. The information on domestic end markets can be difficult to verify. One major question is how much of the product shipped to the Pacific Northwest is trans-shipped Trans-shipments are products that are shipped to foreign markets from a different customs district than the one in which they were manufactured. In the case of Southeast Alaska, lumber manufactured in Alaska is apparently being shipped to foreign markets from the Seattle customs district, making it difficult to track many of the very recent end markets and subsequent demand for manufactured products from Alaska. Other data used in the Brackley et al. (2006a) analysis includes log sources from all ownerships in Southeast Alaska, log and chip shipments out of Alaska to various destinations from all owners, harvest by owner, the Alaska market share for manufactured products in North America, and the North American market share in Japan.

The assumptions used by Brackley et al. (2006a) in their four scenarios are outlined in Table G-1. The Limited Lumber Production and the Expanded Lumber Production scenarios assume the wood processing industry in Southeast Alaska is focused only on processing of sawlogs. The primary difference between these two scenarios is the assumption that Alaska will increase its market share in the North American export market from 0.39 percent to 1.14 percent in the Expanded Lumber scenario, while the Limited Lumber scenario maintains the same market share for Alaska products (0.39 percent) in the North American market as a whole. The North American market share of the entire Pacific Rim market remains at about 50 percent in all scenarios; what changes is the assumption of how much of that larger market will be comprised of wood products from southeast Alaska. In addition, although the market share of North American in the larger Pacific Rim market remains at about 50 percent, the total amount of wood products consumed in that global market is expected to rise by more than 20 percent by 2025, due to increasing populations throughout the Pacific Rim. This projected total increase in consumption is consistent with expected rates of increase in consumption reported in the RPA (Haynes et al. 2007) projections and considerably lower than the rates reported by the United Nations World Trade Organization and Trends Inc, summarized in Brackley et al. (in press).

Basically, the Limited Lumber scenario assumes the market for sawlogs from Alaska will be relatively low and remain so, as the intent of this scenario was to depict the situation the industry has faced over the last several years. The Expanded Lumber scenario assumes there will be some kind of demand stimulus for sawlog material. Such a demand stimulus could come from an industry marketing program, capital investment to make existing sawmills in Alaska more efficient, a change in policy, or some other event that enhances the competitive position of Alaskan producers relative to their competitors in the continental United States, or a combination of such developments. The recent implementation of a limited shipment policy by the US Forest Service in Alaska, in addition to the start-up of a veneer mill in Ketchikan, makes the Expanded Lumber Scenario the most likely scenario representing southeast Alaska's near future (Brackley and Haynes in press).

The Medium Integrated Industry and High Integrated Industry scenarios build on the Expanded Lumber scenario, and in addition, both assume there will be a demand stimulus for low grade and utility logs, which could come about by the construction of one or more chip and utility log processing facilities in Southeast Alaska. These two scenarios assume an increase in markets for Alaska lumber products, but not to the extent assumed in the first two scenarios. These two integrated industry scenarios also assume varying increases in the Alaska share of the North American export market. The Medium integrated scenario assumes an increase in demand for chippable material equivalent to the construction of one chip/utility processing facility in 2008, while the High integrated scenario assumes there will be two increases in demand for chippable material, equivalent to the construction of two chip/utility processing facilities, one in 2008 and another in 2012. Development of a market for low-quality material is referred to as an integrated industry, because all of the material resulting from timber harvest would be processed into marketable products. This is displayed as the construction of medium-density fiberboard (MDF) plants, but the authors make it clear that an MDF plant is only one way a use for low-quality material could develop. Shipments of low-grade material to markets outside southeast Alaska could also be the demand stimulus modeled in these two scenarios.

Table G-1
Characteristics of scenarios defining demand for Alaska roundwood (adapted from Brackley et al. 2006a)

	Scenario			
Characteristic	**Limited lumber production**	**Expanded lumber production**	**Medium integrated industry**	**High Integrated industry**
	Million cubic meters			
Pacific Rim lumber imports:				
Starting	8,077	8,077	8,077	8,077
Ending	11,042	11,042	9,099	10,098
	Million board feet lumber tally			
NA share of Pacific Rim market[a]				
Starting	2,146.7	2,146.7	2,146.7	2,146.7
Ending	2,760.5	2,760.5	2,760.5	2,760.5
	Percent			
AK share NA market				
Starting	0.39	0.39	0.39	0.39
Ending	0.39	1.14	1.60	2.34
NA share of Pacific Rim softwood lumber market	49.29	49.29	49.29	49.29
Estimated low-grade material in sawmill log mix[b]	33	33	10	10
Demand stimulation	no	yes	yes	yes
Market for low-grade logs	no	no	yes	yes

a. NA is North America, and AK is Alaska.
b. Estimating amounts of low grade and utility grade logs delivered to sawmills for use as saw logs meeting the definition of a number 2 saw log at least 12 feet long.

The assumptions and structure used in the Brackley et al. (2006a) model affect the results. An example of a structural aspect is the way total demand is allocated among ownerships. Since the trend analysis model used by Brackley et al. (2006a) calculates National Forest wood demand as a residual (i.e., the share of total demand for Alaska wood products not already accounted for by other ownerships), the model will be sensitive to assumptions about production from other ownerships. They assumed state lands in the region will produce 6.8 mmbf annually. Production from state lands will have an inverse relationship to production from Federal lands, all else assumed constant. If nothing else changes in the model, less production from State lands will mean more demand from Federal lands, and vice versa.

The assumptions in the model also affect the results in various ways. The model assumes that low grade and utility material in the two lumber production scenarios may be unused, sent to chippers, or exported. Changes in their assumptions regarding low grade material utilization may affect the volumes of timber actually removed from timber sales. The model also assumes that in the long run, the volume of sawn material shipped to the total Pacific Rim market (both domestic and foreign) from North American will steadily increase. The proportion stays the same, but the total amounts increase, as the model assumes the entire market is increasing. In the short run this assumption won't affect the results. Over a decade or more, if this assumption proves incorrect, there will be an effect on projected demand. Given population trends in all Pacific Rim market areas, this assumption of increasing demand is very likely. The model also assumes that demand for Alaska manufactured products is directly linked to demand for North American manufactured products through the share calculation. As the North American share of total Pacific Rim markets increases, so will demand for Alaska products, all else constant. In addition, if the proportion of Alaska products in the entire North American market increases, demand for Alaska products will increase, all else constant. These assumptions change from current levels to the levels outlined in Table G-1 gradually throughout the projection period.

Brackley et al. (2006a) list the following issues that will need further research to assist in better predictions in the future. They mention the issue of transshipments. Local sales of lumber within Southeast Alaska are not documented; information is needed as to types of products, prices, and so on. The price differential between foreign and domestic markets for Alaska wood products needs more investigation. Transportation costs are not documented in publicly available databases. The mix of dimension versus shop products is only beginning to be assessed, and conversion factors for these products in Alaska manufacturing are not well developed.

Using Derived Demand Estimates to Estimate Supply

Determining what the demand estimates mean for timber sale offered from National Forest lands in Southeast Alaska involves taking the results from Brackley et al. (2006a) and using them as input to a supply calculation that seeks to meet annual market demand from the forest. The derived demand projections in Brackley et al. (2006a) are one of the inputs to the timber offer calculation developed by Morse (2000). In the original model development (Morse 2000), the derived demand input was total projected harvest volume from the PNW projections developed by Brooks and Haynes (1997). Timber volume in the Brackley et al. (2006a) demand projections in Scenarios 1 (limited lumber) and 2 (expanded lumber) include decked saw logs, cedar log shipments out of Alaska, chip volumes available from sawmill production, and a very small portion of utility or low-grade material that they assumed goes directly to mill chippers. The authors acknowledge that pulpwood grade material may be left in the woods, but they did not include that volume in these two projections. Scenarios 3 (medium integrated) and 4 (high integrated) include decked saw logs, cedar log shipments out of Alaska, chip volumes available from sawmill production., utility, and low-grade material. This is different than previous projections, which projected demand for Tongass timber as volume of timber in timber sales in the forest, and did not disaggregate by species or log grade. The volume reported in Brackley et al (2006a) needs to be adjusted to represent total sale volume needed to meet derived demand estimates for the Limited Lumber and Expanded Lumber scenarios. Table G-2 illustrates the estimated sale volume represented by Brackley et al. (2006a) in their projections.

Table G-2
Tongass National Forest sale volume necessary to supply derived demand for decked log volume and chips reported in Brackley et al. (2006a) (Million Board Feet).

	Projected National Forest Timber Harvest—Alaska (MMBF; includes sawlog, utility, and shipments from Alaska)[a]			
Year	1. Limited lumber	2. Expanded lumber	3. Medium integrated	4. High integrated
2007	49.8	61.9	67	67
2008	49.8	66.4	139	139
2009	51.3	72.4	151	151
2010	52.8	78.5	166	166
2011	52.8	84.5	184	184
2012	54.3	90.5	204	286
2013	55.8	98.1	204	291
2014	57.3	105.6	204	295
2015	58.9	113.2	204	299
2016	58.9	122.2	204	303
2017	60.4	131.3	204	308
2018	61.9	140.3	204	312
2019	63.4	150.1	204	317
2020	64.9	163.0	204	325
2021	66.4	175.0	204	333
2022	67.9	187.1	204	342
2023	69.4	200.7	204	351
2024	70.9	215.8	204	360
2025	72.4	230.9	204	370

a. Annualized calculation to fulfill derived demand scenarios from Brackley et al. (2006a). This table was created using annualized values provide by Dr. Allen Brackley (personal communication, Nov 29 2006) from the model used to develop derived demand estimates in Brackley et al. (2006a). The values reported in this table have been adjusted to include low quality material not included in the demand projections. The Limited and Expanded Lumber scenarios are adjusted from values provided by Dr. Brackley by 33.73 percent to include utility volume (14.56 percent) and grade 3 volume (19.17 percent). The Limited and Expanded Lumber scenarios include saw logs, cedar export, and chip volumes available from sawmill production. Footnote b in Table 2, page 17, Brackley et al. (2006a) states that material delivered to sawmills meets the definition of a number 2 saw log at least 12 feet long , so these calculations are adjusted to account for utility and grade 3 volume. The Medium and High Integrated Scenarios developed by Brackley et al. (2006a) and presented here include saw logs, cedar exports, chip volumes, low-grade material, and utility. These scenarios are not adjusted.

The volume adjustment of wood delivered to sawmills, as in the Limited Lumber and Expanded Lumber scenarios in Brackley et al (2006a), to volume of wood necessary to be offered in a timber sale requires several steps. First is an assessment of the distribution by species in the Tongass National Forest. The net volume, by percent, of growing stock on timberland in Southeast Alaska of commercial softwood species is as follows:

Alaska yellow cedar = 10.02%
Sitka spruce = 26.71%
Western redcedar = 6.18%
Western and Mountain hemlock = 57.09%

The above percentages were calculated from Table 13 in van Hess (2003).

The next step is to assess what percentage of timber is in each grade by species on the ground. The following distribution is calculated using cruise data from thirteen timber sales distributed across the forest. Grades 2 and 6 are combined because some cruises were done before grade 6 (special mill) was implemented.

Western hemlock grade 3:	33.8%
Western hemlock grade 2/6:	55.8%
Western hemlock grade 1:	6.2%
Western hemlock grade 0:	3.2%
Sitka spruce grade 3:	15.5%
Sitka spruce grade 2/6:	64.7%
Sitka spruce grade 1:	13.2%
Sitka spruce grade 0:	6.4%

Utility grade is not part of cruise data. Recent information indicates that 10 percent of all Sitka spruce is utility, and 20 percent of all hemlock is utility. By combining the information about percent of grade by species, the percent of standing timber by species in an average Southeast Alaska stand, and the fact that 10 percent of all Sitka spruce is utility and 20 percent of all hemlock is utility, the following percent of net volume by grade and species for standing timber on the Tongass National Forest was derived.

The following calculation is an example of how percentages of Sitka spruce and hemlock by grade were calculated. The percentage of Sitka spruce in grade 3 (15.5) multiplied by the percentage of Sitka spruce in an average stand (26.71) yields the percentage of Sitka spruce grade 3 in an average stand (4.14 percent). We know that ten percent of this grade 3 Sitka spruce is utility. So, 0.41 percent of Sitka spruce grade 3 is utility and 3.73 percent of Sitka spruce grade 3 remains (see Table G-3). The utility wood from all the grades for Sitka spruce add up to 2.96 percent (Table 3, any errors are due to rounding).

Table G-3
Percent of volume in an average Tongass National Forest stand, by grade and species.

Species and Grade	Percent of Total Volume
Alaska yellow-cedar	10.02
Western red-cedar	6.18
Sitka spruce grade 3	3.73
Sitka spruce grade 2/6	15.55
Sitka spruce grade 1	3.18
Sitka spruce grade 0	1.54
Sitka spruce utility	2.96
Hemlock grade 3	15.44
Hemlock grade 2/6	25.49
Hemlock grade 1	2.84
Hemlock grade 0	1.47
Hemlock utility	11.60

The amount of utility in an average Southeast Alaska timber stand is 14.56 percent. The amount of grade 3 is 19.17 percent. The total amount of low-grade material is 33.73 percent.

The demand numbers reported by Brackley et al. (2006a) are projections of how much wood will be used to meet derived demand projections. Timber sales take years to process, and can be held for several years by the purchaser in anticipation of future needs. Timber sales must be planned and made available in advance of projected needs. The derived demand projections do not include increased timber sale volume in anticipation of increases in wood processing (such as increasing use of existing infrastructure, or construction of new mills). Such timber would need to be sold in preceding years to provide sufficient wood supply.

Demand is an estimate, and translating that demand to on-the-ground sale numbers is also an estimate. The derived demand projections developed by Brackley et al. (2006a) are used to estimate the market demand for the Forest planning cycle. They are also, as noted above, an important input to the model (Morse 2000) that the Forest Service uses to compute the offer target or supply of timber from the Tongass National Forest in a given year. That procedure will be outlined in the next section.

Development of Timber Sale Requirements to Meet Market Demand

The new demand projections in Brackley et al. (2006a) required that the spreadsheet model outlined in Morse (2000) for estimating timber sale goals be modified slightly to reflect the four alternatives in Brackley et al.(2006a). Modification of the spreadsheet model allows continued implementation of Forest Service Sale Preparation Handbook direction (FSH 2409.18, R-10 Supplement 2409.18-2006-5; Ch. 11.4), which basically states that the procedure outlined in Morse (2000) will be followed in developing short-term offer targets.

The general approach of the timber sale offer model (Morse 2000) is to consider the timber requirements of the region's sawmills at different levels of operation and under different assumptions about market conditions and technical processing capacity. These assumptions provide a basis for estimating the volume of timber likely to be processed by the industry as a whole in any given year. The specific steps in the process are outlined below.

Volume of Timber Processed Locally. The first stage in the calculations adjusts mill capacity estimates by the utilization rate assumed for each of the four scenarios, and by the percent of volume expected to come from the Tongass National Forest. This provides an estimate of the volume of logs from the Tongass National Forest likely to be processed into lumber by sawmills in Southeast Alaska under the different scenarios. These figures are then adjusted upward to account for species and grades of timber that are not processed into lumber locally. Given this set of assumptions, the timber supply expected to be consumed in a given fiscal year is then computed.

Inventory requirements. The second stage provides an estimate of the volume of uncut timber inventory to carry under different demand scenarios. As described on pages 19-20 of Morse (2000), target inventory levels depend on the volume expected to be processed each year and the amount of time needed to replenish inventory. The relationship is summarized in Morse (2000; equation 2, page 20) and by the timber inventory requirements in the model itself. Because the volume of timber expected to be processed varies by scenario, timber inventory requirements also vary from one scenario to another.

Harvest Projections. The next step in the process is to incorporate the derived demand estimates developed by Brackley et al. (2006a), adjusted as shown in Table G-2.

Range of Expected Timber Purchases. By subtracting the volume under contract at the beginning of the year from the required inventory , the projected inventory shortfall is calculated. The low range of expected timber purchases is replacement for the volume harvested; the high range is the volume harvested plus the inventory shortfall so that the inventory requirement is met at the end of the year.

The Fiscal Year (FY) 1999 to 2006 Department of the Interior and Related Agencies Appropriations Acts have included appropriations for preparing additional timber for sale to establish a three-year timber supply. In FY 2006, the Act states that:

> That of the funds provided under this heading for Forest Products, $5,000,000 shall be allocated to the Alaska Region, in addition to its normal allocation for the purposes of preparing additional timber for sale, to establish a 3-year timber supply and such funds may be transferred to other appropriations accounts as necessary to maximize this accomplishment.

While the funding level has been different for each fiscal year, the appropriation for preparation of timber sales in order to establish a three year timber supply has remained constant. The reason for establishing a three-year supply is to give timber manufacturers in Southeast Alaska enough volume to maintain a viable inventory for financial integrity and to respond to market changes at their discretion.

Three-year timber supply. The annual timber supply needs from the Tongass National Forest is considered synonymous with the annual timber consumption (i.e., the amount that is expected to be harvested in a given year). To estimate the three-year timber supply, the annual consumption is multiplied by three years.

Timber Pipeline. The Tongass timber pipeline was established as a process to "ramp-up" to the three-year supply over a period of years. It takes about four years to get a project through the analysis and preparation process, to be ready to offer for sale. The additional average annual volume needed to meet the three-year timber supply in a given fiscal year is the three-year timber supply of timber inventory minus timber inventory requirement , spread evenly over a four-year period.

Total Timber Sale Requirement. By taking the median between the low and high range of the volume expected to be purchased, and combining it with the average annual pipeline volume, the total volume anticipated for purchase is estimated.

The measure of meeting the TTRA "seek to meet" and the appropriations bill "three year timber supply" is volume sold from the Tongass National Forest. To meet these objectives, a sufficient amount of volume must be offered to account for any fall-down between the volume offered and the volume sold. The final step in projecting the amount of volume to be purchased is to evaluate the anticipated volume that needs to be offered.

Timber Sale Fall-down. Historically, there has been a difference between the volume offered and the volume sold from National Forest timber sales. The reluctance of purchasers to buy timber sales tends to increase as markets decrease and/or logging costs increase. Mason et al. (2004) examined why some offerings in Southeast Alaska go unsold, and concluded that the probability of a timber sale being successfully sold is tied to downstream markets that are inherently difficult to predict, rather than factors directly controlled by the Forest Service.

Projected Offer Objectives. In an effort to project the amount of volume that needs to be offered for each of the scenarios, the total timber sale projection is increased to account for fall-down and litigation to provide a rough estimate of the volume to be offered for each scenario to meet timber sale objectives.

Conclusion

There have been many changes in the wood manufacturing industry in southeast Alaska in the past decade. Southeast Alaska's two pulp mills and numerous sawmill facilities have closed. Remaining active mills operate at about 13 percent of their estimated capacity, on average. In 2006, the ratio of species sawn in Southeast Alaska mills was about the same as the past six years, with western hemlock in the lead (60 percent of total volume sawn), followed by Sitka spruce (27 percent), western red-cedar (11 percent), and Alaska yellow-cedar (3 percent). Between 2002 and 2006, sources of logs for local mills have been about two-thirds National Forest and one-third State of Alaska, with a very small proportion (less than one percent) from private lands. The destination for material sawn in Southeast Alaska is now primarily other states within the U.S. (Kilborn et al. 2004; Brackley et al. 2006b). Demand for Southeast Alaska wood products in historic export markets, particularly Asia, continues to be low. Hansen (2006) states that U.S. companies have historically jumped into the export market when the domestic market is down, and shifted back to the U.S. market when the domestic market improves. In recent years, the U.S. domestic market has been very attractive with high housing starts and strong prices in many forest product categories. Haynes et al. (2007) state that U.S. demand for forest products is varied and large.

On the supply side, the cost of preparing stumpage for sale and delivering it to mills is generally higher than in Oregon and Washington, due to transportation and labor costs, decreased size of sales, increased fuel costs, legal and procedural challenges to federal timber sales, and more constraints on harvest activity on Federal lands in the interest of resource protection. The uncertainty surrounding Tongass National Forest sale quantities has increased the risk faced by potential purchasers and investors in local processing capacity.

In choosing the offer level, it is important to anticipate the consequences of a "wrong" decision. In terms of short-term economic consequences, over-supplying the market is less damaging than under-supplying it. If more timber is offered than purchased in a given year, the unsold volume is still available for purchasing off-the-shelf or re-offered at a minimal investment. However, a significant shortfall in the supply of timber available for harvest in a given year can be financially devastating to the industry.

Planning the timber program requires more than just pure economic factors. To account for delays in timber sale preparation, administrative appeals, and/or litigation, sufficient contingent volume must be included in the annual timber sale program to account for realistic fall-downs. Budget and organizational constraints limit the extent to which the Forest Service can respond to economic cycles and the associated fluctuations in timber demand. All of these factors must be considered in evaluating the market demand for timber and setting timber offerings. In the final analysis, planning the timber sale program is an exercise in professional judgment. The purpose of this paper is to identify the extent to which economic analysis contributes to this decision-making process.

Acknowledgements

This paper was improved with edits and information from Dr. Allen Brackley and Dr. Richard Haynes. US Forest Service Alaska Region staff at the Regional Office and the Tongass National Forest also provided important data.

Appendix H
Comments and Responses

A. Introduction

The Tongass Land and Resource Management Plan Amendment Draft Environmental Impact Statement (EIS) and the Draft Proposed Land and Resource Management Plan were completed and mailed out (beginning January 4, 2007) to the 2,300 organizations and individuals on the Tongass National Forest's mailing list. The document and supporting documents were also posted on the project web site (http://www.tongass-fpadjust.net).

The Notice of Availability for the Draft EIS was announced in the Federal Register on January 12, 2007, initiating the 90-day formal public comment period. The 90-day comment period was subsequently extended from April 12 to April 30, 2007 because severe weather in Southeast Alaska caused some of the public meetings/hearings to be rescheduled and delayed some of the Forest's Tribal consultation activities.

This appendix presents a summary of the comments received during the public comment period and provides the Forest Service's responses to these comments. In addition, Attachment A provides copies of the letters received from government agencies, elected officials, and tribal governments.

Public Meetings

Twenty-five public meetings were held to elicit public comment over this period. These meetings included 23 meetings in communities located throughout Southeast Alaska, a meeting in Anchorage, and an electronic public meeting held on the internet (Table H-1). These meetings included both open houses and hearings. The open houses were informal meetings where participants could review maps and other information, and ask questions or discuss the Draft EIS or Forest Plan with Forest Service representatives. The hearings were formal opportunities for participants to provide oral testimony on the Draft EIS. A total of 204 people provided oral testimony at these hearings, with several people testifying at more than one hearing.

Public Input

The Forest Service received 84,509 separate pieces of input during the public comment period. These pieces of input, referred to here as "comment documents," were provided in a number of different forms, including email, letter, fax, public testimony, and online comment form (http://www.tongass-fpadjust.net). As part of the initial comment evaluation process, comment documents were initially divided into unique comment documents and form comment documents.

A comment document is considered a form document when copies of the same document (letter, email, comment form, etc.) are submitted by five or more people. Form comment documents are typically generated by special interest organizations that encourage their members to write, and provide a written template for them to use. In some cases members are encouraged to add their own personal message to the template.

Table H-1.
Locations and Dates of the Public Meetings

Community	Location	Date
Anchorage	Loussac Library Assembly Chamber	3/30/2007
Angoon	Community Center	4/13/2007
Coffman Cove	City Hall	2/20/2007
Craig	Craig Community Hall	3/1/2007
Edna Bay	Community Building	3/21/2007
Gustavus	School	3/14/2007
Haines	Borough Chambers	3/6/2007
Hoonah	Ranger District	3/7/2007
Hydaburg	City Hall	2/27/2007
Internet Meeting	http://www.tongass-fpadjust.net/	3/22/2007
Juneau	Centennial Hall	2/27/2007
Kake	Community Hall	3/21/2007
Ketchikan	Discovery Center	3/1/2007
Naukati	School Commons	2/21/2007
Petersburg	City Council Chamber Hall	2/22/2007
Point Baker	Community Building	3/12/2007
Port Protection	Community Building	3/22/2007
Saxman	Saxman Community Center	3/13/2007
Sitka	Sheet'ka Kwaan Naa Kahidi (Community House)	2/22/2007

Whale Pass	Library	2/23/2007
Wrangell	Nolan Center	3/20/2007
Yakutat	High School Auditorium	2/28/2007

Unique Comment Documents

Approximately 2.5 percent (2,102) of the comment documents received were classified as unique comment documents. The vast majority of these unique documents (1,898) were received from addresses in the U.S. Eight unique comment documents were received from Canada, with one apiece from Great Britain, France, Switzerland, and Japan. The remaining 192 unique comment documents were received with no address information.

Alaska residents submitted 620 unique comment documents, including 200 comments submitted as testimony at public hearings. These comment documents accounted for approximately 29 percent of the total unique comment documents received. The next three most frequently represented states were Washington (180 comment documents, 8 percent), Florida (130 comment documents, 5 percent), and Oregon and Pennsylvania (105 comment documents each, 5 percent each).

The total number of unique comment documents received in response to this Draft EIS (2,102) is approximately 70 percent of the number (2,983) submitted during the public comment period for the 2002 Draft Supplemental EIS (SEIS) for Wilderness Recommendations on the Tongass (USDA Forest Service 2003).

Form Comment Documents

The vast majority (approximately 97.5 percent) of the comment documents were form responses. Thirteen different form comment documents were identified, with the number of copies ranging from 5 to 43,216.

Approximately 95 percent of the form comment documents received were from addresses in the U.S. Form comment documents were received from all 50 states. Residents of California accounted for

15,600 (19 percent) of the form comment documents sent from within the U.S. The next three most frequently represented states were New York (6,220 comment documents, 8 percent of U.S. form comment documents), Florida (4,330 comment documents, 5 percent), and Illinois (3,430 comment documents, 4 percent). Alaska residents submitted 350 form comment documents, less than 0.5 percent of the total received from U.S. residents.

Form comment documents were also received from 89 other countries. Approximately 15 percent of the form comment documents from other countries were from Canada (600 comment documents). The next three most frequently represented countries were Great Britain (540 comment documents, 13 percent of non-U.S. form comment documents), Australia (280 comment documents, 7 percent), and France (120, 3 percent). In addition, 1,130 form comment documents were submitted without any address information.

The large number of documents and locations involved reflects the importance of the Tongass National Forest at a national and international level. It also reflects the membership and geographic reach of the organizations that prepared the original written templates, as suggested by the concentration of form comment documents from addresses in California and New York.

The total number of form comment documents received in response to this Draft EIS (82,407) is less than half the number of form comment documents (174,000) submitted during the public comment period for the 2002 Draft SEIS (USDA Forest Service 2003).

Comment Document Evaluation

Public comments were submitted to the Forest Service via online comment form, email, U.S. Mail, as testimony at a public hearing (in-person or online), and via hard copy comment form. Approximately 97.5 percent of the total comment documents (82,400) were sent via email. This percentage was higher for the form comment documents with 99.3 percent sent via email. Email accounted for 29 percent (about 600 messages) of the unique comment documents. More than half (59 percent, 1,220 letters) of the unique comment documents were sent via U.S. Mail.

Each comment document was assigned a unique identifier (number) upon receipt and entered into a database. Documents were numbered in the order received by the comment management team. Summary demographic information for each response was entered into a database, including the name and address of the comment author (when provided), the type of comment author (individual, government agency, environmental organization, etc.), and the method of transmittal (online comment form, email, U.S. Mail, public hearing testimony, hard copy comment form).

Members of the comment management team read each comment document and identified the comments within each document. Comments were identified for one copy of each form comment document. Comments were defined for the purposes of this initial identification phase as a coherent segment of text that stood alone as a suggestion, idea, request, or critique. Comments were delineated on a hard copy of the comment document and each comment was assigned a number. The comment number was entered into a database and assigned to a coding category. Up to three key words or terms that further characterized the comment, along with additional notes, were entered in separate fields in the database, as appropriate. The initial coding categories corresponded for the most part with the resource areas addressed in the Draft EIS. A copy of each coded comment document was scanned and saved as a unique PDF file.

Comment Summaries and Responses

The database allowed the comments to be sorted by coding category and key words. Resource specialists and Forest Service managers reviewed all the comments and consolidated the individual comments into logical comment summaries, developed responses to the comment summary, and revised the analysis or text in the Final EIS, as appropriate. The comment summaries and responses are presented in Section B of this appendix. Some comment summaries represent a concern raised once; others represent a concern, opinion, or preference that was repeated in a number of different comments. This is generally indicated at the beginning of each comment summary.

The comment identification process erred on the side of inclusion and more than 5,500 individual comments were identified and coded. Many of the identified comments consisted of statements of opinion or preference, and did not require a factual response. Comment summaries and responses are, however, presented in Section B for a number of these types of comments, primarily to provide information to the public or clarify popular misconceptions.

In accordance with 40 Code of Federal Regulations (CFR) 1503.4, the Forest Service generally considered responding in five basic ways to the substantive public comments identified in the following sections.

1. Modifying alternatives.
2. Developing and analyzing alternatives not given serious consideration in the Draft EIS.
3. Supplementing, improving, or modifying the analysis that the Draft EIS documented.
4. Making factual corrections.
5. Explaining why the comments do not need further Forest Service response.

Review of the public comments resulted in Alternative 1 being modified between the Draft and Final EIS with all Inventoried Roadless Areas being removed from the suitable land base under this alternative. After substantial consideration, it was decided that the range of alternatives was sufficient and captured the effects of all possible new alternatives. The results of the public involvement and comment process did, however, lead to a number of improvements, clarifications, and updates between the Draft and Final EIS. These changes are identified where applicable in the following section (Section B).

The following section presents the comments and responses developed by the resource specialists and Forest Service managers that comprise the Interdisciplinary Team for this project. Copies of the comment documents received during the public comment period from government agencies, elected officials, and tribal governments are presented in Attachment A. All of the responses received are available for review in the project planning record.

B. Comment Summaries and Responses

This section of the Appendix presents a summary of all of the substantive comments, written or oral, received during the public comment period for the Draft EIS and provides Forest Service responses to these comments. The comments and responses are organized and presented in the following categories:

General Comments

- Alternatives
- Cumulative Effects
- Energy
- Forest Plan – General
- Forest Plan Monitoring and Adaptive Management
- General
- Key Issues
- Multiple Use
- Public Involvement
- Restoration
- Schedule
- Standards and Guidelines
- Tribal Consultation

Resource and Issue Comments

- Climate and Air
- Economic and Social Environment
- Fish and Watersheds
- Geology, Soils, Karst and Caves
- Heritage and Sacred Sites
- Lands
- Minerals
- Recreation, Tourism and Scenery
- Roadless Areas and Wilderness
- Subsistence
- Timber
- Transportation and Utilities
- Wetlands
- Wildlife, Biodiversity and Plants

Specific Geographic Area Comments

- Specific Geographic Area Comments and Responses
- Specific Places Identified for Protection

General Comments

The General Comments section is divided into the following subsections:

- Alternatives
- Cumulative Effects
- Energy
- Forest Plan – General
- Forest Plan Monitoring and Adaptive Management
- General
- Key Issues
- Multiple Use
- Public Involvement
- Restoration
- Schedule
- Standards and Guidelines
- Tribal Consultation

Alternatives

Comment: Many comments expressed support or opposition for one or more of the seven alternatives. Support for Alternative 1 which would provide the lowest level of timber harvest and the highest level of roadless area protection was most prevalent. At the other end of the spectrum many respondents expressed support for Alternative 7, which provided the highest level of timber output and would support a fully integrated timber industry.

Response: The seven alternatives evaluated in the Final EIS present a range of reasonable alternatives developed in response to the three significant issues identified for this project. Clearly, people disagree on what the appropriate mix of timber harvest and roadless area protection should be on the Tongass. They also disagree about the risk the different alternatives pose to wildlife viability and other potentially affected resources.

Comment: Some respondents felt that the range of alternatives was inadequate. Some believed that Alternative 1 had too much old growth logging and road building, or that no old-growth should be cut. Others felt that Alternative 7 might not provide an adequate amount of timber to sustain an integrated timber industry in Southeast Alaska and should be modified to eliminate old-growth reserves (OGRs), roadless area protections, beach buffers, and Class III stream riparian buffers. Some respondents were opposed to any timber harvest, while others commented that too much land is being left undeveloped and at least 1.5 million acres were needed for timber production and pointed out that this would still leave over three-quarters of the old-growth forest undeveloped.

Response: Alternative 1 was modified between the Draft and Final EIS to reduce the amount of logging and road building. All Inventoried Roadless Areas were removed from the suitable land base, as were a number of areas of concern, such as Kuiu Island. The Forest has an obligation under the Tongass Timber Reform Act (TTRA) to seek to meet the demand for timber. Alternative 7 has an adequate land base to exceed the highest levels of potential future timber demand as identified by McDowell Group 2004 and Brackley et al. 2006. Alternative 7 does not include OGRs or 1,000-foot beach buffers. Alternative 7 (as modified in the Final EIS) does not include OGRs, 1,000-foot beach buffers, or buffers on Class III streams.

Comment: A number of comments stated that the analysis was too narrowly focused on timber demand resulting in an inadequate range of alternatives. These respondents felt that the Draft EIS should have examined alternate desired conditions for the Forest and a new array of goals and objectives. Other items such as designation of new wilderness areas, road management options, the growth in recreation demand, and other OGR options were cited as examples of topics that should have been considered in more detail. Some felt that a full revision of the Forest Plan was necessary.

Response: This analysis effort is being conducted in response to the August 2005 Ninth Circuit Court of Appeals Court Decision which directed the Forest to take a second look at timber demand, the alternatives considered in response to timber demand, and cumulative effects. To respond to the Court in a timely manner, the decision was made to limit the scope of the analysis and amend the Forest Plan. The suggested topics were covered in the 1997 Plan Revision that this Amendment brings to completion. Chapter 1 of the Final EIS explains the Purpose and Need for the analysis and describes the history of forest planning on the Tongass. Forest planning is a dynamic process with periodic reviews occurring to assess the need for additional changes.

Comment - Concern was expressed that an alternative that maximized timber harvest within the roaded land base was not developed.

Response: Alternative 1 was modified for the Final EIS to remove all Inventoried Roadless Areas from the suitable land base. The timber output level associated with Alternative 1 is intended to represent the level of timber harvest that has occurred over the last several years. While it is true that more timber might be harvested from this land base, it is unclear if it would truly be sustainable. As the land base decreases, standards and guidelines that coincide and other spatial issues become more problematic. While some feel that more intensive management on a smaller land base is appropriate, others have concerns about issues such as wildlife habitat connectivity and water quality. Some analysis has been done regarding the maximum amount of timber that could be harvested from the roaded land base, but a separate alternative was not analyzed in detail.

Comment: Concern was expressed that a preferred alternative was not identified in the Draft EIS.

Response: As noted in the cover letter that accompanied the Draft EIS, the Forest Supervisor for the Tongass National Forest, chose not to identify a preferred alternative for the Draft EIS because he hoped that public input in response to the Draft EIS would help the forest make a more informed decision. The Forest Service wanted to get comments regarding the merits of all the alternatives and ideas about possible combinations of alternatives that would be acceptable. The Forest Supervisor and other members of the planning team felt that identifying one of the alternatives as the preferred in the Draft EIS could be counterproductive and might lead to polarization rather than a collaborative discussion.

Comment: Some felt they could only support an alternative that gave great emphasis to conserving the forest for future generations rather than highly weighting immediate extractive use of the forest.

Response: All the alternatives in the Final EIS are judged to be sustainable and conserve the forest for future generations.

Cumulative Effects

Comment: Several comments urged that the cumulative effects of past logging, particularly on private lands, be taken into account when considering future timber harvest.

Response: Cumulative effects were one of the deficiencies of the 1997 Final EIS identified in the August 2005 decision issued by the U.S. Court of Appeals for the Ninth Circuit. As noted in the cover letter that accompanied the Draft EIS, considerable work was completed for this analysis to acquire information on past timber activities conducted on lands managed by the State of Alaska and Alaska Native Corporations. This information is included in the cumulative effects discussions presented by potentially affected resource in the EIS and supplements the extensive cumulative effects analysis that was completed for the 1997 planning effort.

Energy

Comment: One comment noted that as fuel and other energy costs continue to increase there will be increased interest in wood products and hydroelectric projects on the Tongass. These things, the comment noted, will help reduce the region's dependence on fossil fuels. Another comment expressed support for using wood waste and low value material as fuel and cited the current project in Craig as an example that should be identified in the Final EIS.

Response: Biofuel and hydroelectric projects do have the potential to reduce fossil fuel consumption, as noted in the Final EIS. The wood burning boiler installed by the community of Craig to heat school buildings and a recreation facility is identified in the *Economic and Social Environment* section of the EIS as an example of one of several developments that hold future promise for the timber industry in Southeast Alaska. As noted in the EIS, several other communities have also shown interest in this type of system

Comment: Several comments stated that the site for the airport identified in the Kootznoowoo Wilderness should be on the EIS maps. These maps should also show prospective hydroelectric, wind, tidal, and geothermal energy sites, as well as native allotments.

Response: This Plan Amendment responds to a narrow set of issues defined by the Ninth Circuit Court and to some additional issues identified in the 5-year Plan Review. These maps are not intended to illustrate all aspects of Forest resources. However, the Angoon Hydroelectric Project will be included in the Transportation and Utility Systems LUD on the Forest Plan map.

Forest Plan - General

Comment: Some comments stated that the Tongass National Forest should be divided into sections or different units for various reasons and each area should be managed separately, taking into consideration the uniqueness of each area or applicable laws.

Response: The Land Use Designations (LUDs) identified in the current and proposed Forest Plans consider the uniqueness of areas and allow for the tailoring of management direction to match the characteristics of each area. The LUDs take into account all applicable laws and regulations, including TTRA, the Alaska National Interest Land Conservation Act (ANILCA), and Wilderness designations by Congress.

Comment: One respondent felt the Forest Plan should be specific to each separate island or appropriate island-groupings, with unique management plans and separate standards and guidelines applied to each island or island-grouping.

Response: Forest planning takes place at two levels: 1) programmatic planning, as found at the Forest Plan level, and 2) project-specific planning that addresses particular site-specific projects, such as proposed timber sales or recreation developments. Intermediate planning as proposed in this comment is beyond the scope of this analysis. The Forest Service normally evaluates specific projects at the landscape assessment or site-specific level during Forest Plan implementation. Nothing precludes the Forest Service from applying adaptive management techniques based on appropriate analysis whether at the smaller landscape or project level, or at the level represented by the Forest Plan.

Comment: Concern was expressed that the Experimental Forest LUD should not be classified as a Development LUD but instead should be in the Natural Setting LUD group because of the restrictions to development.

Response: Development and Natural Setting are broad categories that are useful for comparing LUD designations in alternatives. The Experimental Forest LUD may be a good example of one that is somewhere in between these two categories.

Comment: Some respondents felt that a separate LUD was needed for customary and traditional uses. Others asked for an economic zone around certain native communities so that their needs would be recognized and have highest priority in those areas.

Response: Traditional and subsistence uses are widespread and often compatible with other uses and, as a result, the current and proposed Forest Plans emphasize the importance of these uses across the Forest on most lands rather than identify certain zones. Maps of community use areas were considered in alternative development and determination of effects (see the *Subregional Overview and Communities* section of the EIS).

Forest Plan Monitoring and Adaptive Management

Comment: Numerous comments were received regarding the use of adaptive management. Most generally accepted or supported adaptive management but advised caution with respect to the potential for misuse. Others expressed concern over the use of adaptive management and assumed that the application of adaptive management techniques would mean less protective measures for a particular resource. Concern was also expressed that there needed to be a monitoring program in place with adequate funding.

Response: Site-specific projects or activities that implement adaptive management are typically applied and reviewed at the project level, though some may be applied Forest-wide. The Forest Plan monitoring program considers adaptive management.

Comment: One comment noted that the information needs for the Conservation Strategy identified in Appendix B to the 1997 Forest Plan were presented as a static list of studies that were priorities in 1997 with no mechanism that allowed this list to evolve over time. The comment noted that funding for research and monitoring is limited and stated that Appendix B to the amended Forest Plan needs to incorporate a "dynamic, well-defined process to identify and prioritize information needs, and compare results against original hypotheses."

Response: Appendix B of the Final Proposed Forest Plan has been updated to better reflect the ongoing nature of pursuing new information and the fact that many agencies, academics, and others are involved in this process. The appendix also acknowledges that coordination between different agencies and researchers is important.

Comment: Many general comments on Forest Plan monitoring were received. Identified concerns included issues related to adaptive management, evaluation needs and working with cooperative agencies. Some comments were concerned about the overall ability of the Forest to fund adequate and appropriate monitoring.

Response: The Monitoring plan for the Final Proposed Forest Plan was extensively edited from the Draft EIS. These changes reflect these issues in light of declining budgets while maintaining a robust monitoring plan that is adaptable and serves the needs of the Forest Plan.

General

Comment: One respondent felt that the Draft EIS failed to adequately scope and analyze the effects of emergencies and natural disasters.

Response: The potential effects of emergencies and natural disasters are beyond the scope of this analysis. It may, however, be noted that the Forest Service has emergency procedures in place to deal with these types of events. These measures include coordination with other state and federal agencies.

Comment: Some respondents felt that the Forest Plan objectives were becoming more general and vague. They suggested that the objectives be rewritten as narrowly defined, precise, and measurable statements. One respondent was particularly concerned about the removal of specific trail construction targets, which are expressed in miles of new trail in the existing Forest Plan.

Response: Some of the objectives were edited for clarity in the Proposed Forest Plan. In the past, objectives were often expressed as targets in discrete, measurable units, such as numbers of acres, structures, or miles. This often resulted in a disconnection between the broader goals the Forest Plan is intended to accomplish and these counts of acres, structures, or miles. These types of objectives also failed to take into account changes in budget from year-to-year.

Comment: Concern was expressed that changes to Research Natural Areas and Experimental Forests might preclude the State from exercising its wildlife management responsibilities. In particular concern was expressed about the required approval of routine activities by the Director of the Forest Service's Pacific Northwest (PNW) Research Station. Reference was made to various Memorandums of Understanding (MOUs) that recognize the State's responsibilities for wildlife management.

Response: The Forest Service recognizes the State's responsibilities for wildlife management. Coordination will be needed between the State, the PNW Research Station, and the affected Ranger Districts to ensure that each can fulfill its responsibilities.

Comment: One respondent wanted the Forest Plan to recognize that commercial ventures for raising forest products are a legitimate and authorized use of the National Forest. They also wanted the Plan to allow for production of traditional and customary food stocks in commercial quantity in wilderness areas.

Response: Commercial ventures such as this can be considered on a case-by-case basis. There are too many variables related to the type of venture and the location to make such a broad statement in the Forest Plan. In general, we do not feel that commercial ventures such as this are appropriate in designated Wilderness though such proposals could be examined through the special use permitting process.

Comment: One comment recommended that the Forest Service prohibit all pesticide use on the Tongass. Another comment expressed opposition to "area pesticide spraying" and stated that herbicide spraying should "not be used in case of human health emergencies." Another comment expressed a general concern about herbicide use.

Response: The Forest Service acknowledges the concerns expressed regarding pesticide use, but we are not willing to ban all use on the Tongass. Pesticide use is a tool that needs to be carefully evaluated on a case-by-case basis with the appropriate site-specific analysis, including public comment.

The Tongass does not use herbicide for Forest management. Although it is possible that it may be needed to control invasive species in the future, there are no plans currently to do so. Any plans for herbicide use would require a separate National Environmental Policy Act (NEPA) analysis.

Comment: A number of comments stated that the Draft EIS was flawed and recommended that a revised or Supplemental Draft EIS be issued. Various reasons were cited including the Forest Service's failure to conduct an Analysis of the Management System (AMS), complete the Conservation Strategy Review process initiated in 2006, disclose and respond to scientific opinion that opposed the proposed action, fully disclose when uncertainty exists, and include important information in the Draft EIS.

Response: Resource-specific and procedure-related concerns are addressed in detail elsewhere in this comment response volume. Specific concerns about the conservation strategy are, for example, addressed under Wildlife and Biodiversity. Detailed critiques of the timber demand projections developed for this Amendment process are disclosed and addressed under Timber Demand in the Economic and Social Environment section. The AMS is addressed in response to the following comment summary.

The Forest Service believes that the Draft EIS fully disclosed and responded to conflicting scientific opinion and identified areas where there is known uncertainty beyond that typically associated with all types of scientific impact analysis. These discussions have been expanded in the Final EIS, where appropriate, and this comment response volume discloses and responds in detail to the opposing scientific and other opinions provided by individuals, organizations, and others in response to the Draft EIS and Proposed Forest Plan.

In addition, we believe that the Draft EIS adequately informed the public about the alternatives considered and the potential effects so that informed comments could be received. The comprehensive Forest Plan Adjustment website established for this project (www.tongass-fpadjust.net) made information available to interested parties as the analysis progressed and provided the opportunity for the public to provide feedback and input throughout the process.

Comment: Some respondents felt that the Forest Plan Amendment process was flawed because no new AMS was prepared. One comment stated that the "primary goal of the AMS is to analyze Forest resource supply and demand and determine whether current management direction should change in response to these conditions." The comment argued that an AMS is necessary to determine which lands are suitable for timber production, considering whether the land has been withdrawn by Congress or administratively, can be reforested within 5 years, and if irreversible resource damage would occur if timber is harvested.

Response: The Forest completed the various steps in an AMS and an updated AMS is in the project planning record. The suitability determination was the most complete analysis done anywhere to our knowledge. Building on past efforts, including the recent SEIS (USDA Forest Service 2003) which completed an AMS for all roadless and wilderness areas, we used GIS data to map all areas withdrawn by Congress or administratively. We then mapped unstable areas, sensitive riparian areas, and areas with soil concerns and removed these areas from the suitable land base. Each remaining area of productive forest land was subsequently divided into logical logging settings and individually evaluated using existing NEPA analyses, aerial photographs, LiDAR, LANDSAT, GIS data, and local knowledge. Those areas that appeared to have problems were flagged and risk factors were assigned based on the problems that were identified. Areas considered unsuitable were identified. Logging engineers then identified individual logging settings and the type of yarding methods and road access that would be needed to log each unit. They also identified the silvicultural system that would be most likely to be used. This process took several months and resulted in the best estimate of timber supply we have ever had, both for total supply and for that portion of the total supply that will likely be economical to harvest. The demand for Tongass timber was identified in the timber demand analysis prepared by the PNW Research Station (Brackley et al. 2006a).

Comment: A number of comments stated that the Forest Service should use the "best available science" or "sound science" in the EIS analysis. A number of these statements were made with respect to the existing Conservation Strategy Standards and Guidelines, which some argued are not based on sound science. Others stated that the Final EIS should fully incorporate the findings of the 2006 Conservation Strategy Review. Others made general statements that some of the impact analyses presented in the Draft EIS were not based on scientific analysis, but were just speculation or opinions.

Response: Specific concerns about the scientific basis of particular analyses or components of the Forest Plan are addressed in detail elsewhere in this comment response volume. Specific concerns about the existing Conservation Strategy Standards and Guidelines are, for example, addressed under Timber. Concerns about the Conservation Strategy Review are addressed under Wildlife and Biodiversity.

It is not possible to provide a specific response to general assertions that the Draft EIS analysis is speculative or just opinions, but, in general, the Forest Service believes that the Draft EIS employs the best available science, to the extent possible. The Draft EIS was reviewed by scientists at the PNW Research Station and additional analysis, information, and citations were added to the Final EIS based on the results of this review and comments from the public and other agencies.

Comment: One respondent felt that using total development LUD acres in alternative descriptions and effects analyses overstates potential impacts as only a small percentage of the development LUDs would be developed or otherwise impacted.

Response: The distribution of the Forest by LUD group (Intensive Development, Moderate Development, Natural Setting, and Wilderness) provides a general basis for comparison between different alternatives. Other information, such as suitable acres, provides another basis of comparison about the relative impacts of each alternative.

Comment: Many respondents were opposed to road construction, which was often mentioned in connection with clearcutting. Road-related concerns often centered around impacts to wildlife habitat and reductions in roadless character.

Response: The alternatives feature a wide range of road construction levels and potential effects to roadless areas. Alternative 1 was modified for the Final EIS to greatly reduce the road construction miles and eliminate effects to Inventoried Roadless Areas. However, even in this alternative some road construction is needed to access lands suitable for timber harvest.

Comment: Several comments urged that the Tongass Plan Implementation Team papers be reviewed and incorporated in the Final EIS, as necessary.

Response: These papers have been reviewed and incorporated in the Final EIS, as appropriate.

Comment: Some respondents expressed interest in greater protection of the coastline and coastal valleys then occurred in the past.

Response: The 1997 Forest Plan added extensive protection measures such as the adoption of 1,000-foot beach and estuary buffers. All alternatives, with the exceptions of Alternative 7, retain these important features. Alternative 7 has a 1,000-foot estuary buffer and a 500-foot beach buffer.

Comment: One comment expressed concern that the Draft EIS said the 5-Year Forest Plan Review was part of the purpose and need for the Amendment despite the fact that the Forest Supervisor concluded at the end of the 5-Year Review that the plan did not need to be revised at that time.

Response: The 5-year review pointed out many areas that needed updating but that overall there was no reason to begin a full scale revision of the Forest Plan. With the need to respond to the Court order of August 2005, it seemed like an excellent opportunity to address some of those items from the 5-year review at the same time we responded to the Court.

Comment: One comment noted that a reduction in timber harvest in temperate zones results in the transfer of the needed harvest to tropical areas.

Response: It seems reasonable to assume that demand for timber will be met and, provided demand remains constant or increases, a reduction in harvest in one area will likely lead to an increase in harvest somewhere else. The Forest Service is required to seek to provide a supply of timber from the Tongass that meets market demand. The Proposed Forest Plan alternatives address a range of potential demand estimates. None of the proposed alternatives are expected to result in a transfer of harvest that would otherwise occur on the Tongass to other regions of the world.

Comment: One comment requested that the Final EIS explain the relationship between the Amendment and previous planning documents. Concern was also expressed about the statement on page 2-8 of the Draft EIS that: "The individual alternative descriptions on the following pages only identify items that are not consistent with the current Forest Plan or Proposed Forest Plan." Several respondents found this confusing and were concerned that this would result in information not being fully disclosed.

Response: The Final EIS and Record of Decision (ROD) will clarify this relationship. In summary, the amended Forest Plan and ROD will be stand alone documents giving management direction for the Tongass. Previous analyzes, such as the 1997 Final EIS, are tiered to and will continue to be used at the project level.

The alternative descriptions presented in Chapter 2 of the EIS focus on the main changes from the current Forest Plan to the Proposed Forest Plan, as noted in the above quote. The entire Proposed Forest Plan, which includes all the unchanged elements of the current Forest Plan, as well as the proposed changes, was published with the Draft EIS. A revised version of the Proposed Forest Plan has also been published with the Final EIS.

Comment: One respondent felt that the Draft EIS should discuss in more detail the laws related to the management of the Tongass and other national forests. They stated that "these statutes and their current applicability should be more clearly referenced in the (Forest Plan) and the Draft EIS."

Response: The Draft and Final EIS documents discuss and reference the laws that are most directly applicable to this Forest Plan Amendment. These laws include TTRA, the National Forest Management Act, and ANILCA. There are, however, many other laws that have a direct bearing on the management of national forests, as well as implementing regulations and court decisions interpreting these laws. These laws, regulations, and court decisions are not specifically discussed in the EIS, but additional general information is available on the Forest Service's web site (www.fs.fed.us).

Key Issues

Comment: There were several comments regarding the three key issues. Some thought that issues one and three were very much the same. Other comments identified additional issues that the comment authors thought should be identified as separate key issues. Subsistence, salmon conservation, and the social and economic well-being of Southeast Alaska communities were proposed as other key issues.

Response: Key issue one emphasizes the protection of high value roadless areas from development. Key issue three emphasizes the protection of wildlife habitat and biodiversity. While the two issues are certainly linked, they are two different issues. The key issues for the EIS were developed based on a review of the public input received prior to publication of the Draft EIS and are directly related to the purpose and need for the Forest Plan Amendment process. This issue identification process is discussed in the *Public Issues* section of Chapter 1 of the EIS. The other resources and resource uses identified in the above comment summary are also important aspects of the Forest Plan and are addressed in the proposed Forest Plan and the EIS, as appropriate.

Comment: One comment stated that Allowable Sale Quantity (ASQ) was not an indicator of a viable economy. They felt that Southeast Alaska could have a viable economy without timber harvest.

Response: The ASQ is not used in the EIS as an indicator of a viable economy. Rather it is a measure of the maximum potential harvest that could be achieved under each alternative. Definitions of viable vary, but based on recent trends it appears that population and employment in Southeast Alaska has declined slightly and stayed relatively the same, respectively, despite relatively large declines in timber harvest over the past decade and more. Other indicators suggest that some communities have been more negatively affected by this decrease than others (see the *Subregional Overview and Communities* section in the EIS).

Comment: One comment requested that the description of Key Issue 2 be revised as follows (underlined words to be added):

> **The Tongass National Forest needs to provide a sufficient <u>economic</u> timber supply to meet market demand and help maintain a vibrant, <u>diverse</u> economy"**

The comment defined "economic" timber as timber that a purchaser can harvest at a profit.

Response: The description of Key Issue 2 presented in the Draft EIS summarizes the issue adequately and remains unchanged in the Final EIS. Timber demand and concerns regarding timber supply are discussed in more detail under Timber Demand in the Economic and Social Environment section of this appendix.

Multiple Use

Comment: Many respondents talked about the importance of multiple use in guiding future management of the Tongass. A balanced approach to managing the Tongass was a common theme. But there were two distinct perspectives. Some felt that the multiple use concept supports the idea of a large timber industry and higher levels of timber harvest. They often mentioned the relatively small area of the Tongass open to timber harvest and stated that these lands should be managed intensively. Other comments discussed the idea of multiple use in the context of the various other uses found on the Tongass. They felt that timber harvest was emphasized too much and, when done at a large scale, was not compatible with other uses.

Response: Each alternative in the Final EIS represents the concept of multiple use by incorporating the full spectrum of land uses, from designated wilderness to lands emphasizing timber management or mineral extraction. Each alternative balances these uses differently and the range of alternatives covers the various points of view expressed in the comments.

Comment: One comment argued that the "multiple use" concept is: "a fancy way of (bypassing) the trust responsibility of protecting the habitat" and characterized this concept as a "popular political maneuver to try to please everyone a little, and still damage the habitat by allowing tree cutting so roads can be built without taxpayer expense."

Response: Multiple use is required by law (the Multiple Use-Sustained Yield Act of 1960). Changing this policy would require an act of Congress and is beyond the scope of this analysis. The Forest Service disagrees with this characterization of the application of the multiple use process.

Comment: Some felt that this Forest Plan Amendment should not decrease the land area open to commercial uses such as logging and mining. A number of comments cited ANILCA as indicating that no more restrictions would be put into place.

Response: The Final EIS looks at a wide range of alternatives built around the issue of timber harvesting. Three alternatives feature a reduced land base available for logging, two alternatives would increase the lands available, and the remaining two would maintain the current land base. No major changes to mining opportunities are proposed.

Public Involvement

Comment: Some respondents had suggestions for how the public meetings on the Draft EIS could have been conducted differently. For example, one person suggested that a question and answer session be held between the open house and the public hearing.

Response: There are many different ways to conduct a public meeting. The people that attend our meetings often have very different objectives for being there. Some are interested in listening to presentations and learning about the issues and planning process. Others want to ask questions about issues or places of concern to them. Others have formed their opinion and want nothing more than to have a forum to express it. We believe that our meetings, which featured an open house followed by a public hearing, made efficient use of the available time and offered a format that met most peoples' needs.

Comment: Some respondents requested that the Forest Service have public meetings in more small communities. Elfin Cove was one particular community mentioned.

Response: The Forest Service held public meetings in 24 Alaska communities during the comment period for the Draft EIS. We also held an internet public meeting and hearing open to anyone with computer access. In addition, Forest Service staff were available by telephone or email to answer questions, and comments could be submitted via letter, fax, email, or online comment form. We worked hard to get to as many of the smaller communities as possible as evidenced by public meetings in smaller communities such as Whale Pass, Port Protection, and Point Baker. One of the reasons the comment period was extended by 18 days was to reschedule public meetings cancelled by the weather. Unfortunately, we were not able to visit all of the communities in the region.

Comment: Some respondents felt that the 90 day comment period for the Draft EIS was not adequate and that the comment period needed to be extended.

Response: The Forest Service believes that the comment period was adequate. This is especially true given that much of the information in the Draft EIS and Proposed Forest Plan has been on the project website (www. tongass-fpadjust.net) for months. For example, the track changes version of the Forest Plan showing many of our proposed changes was posted during the summer of 2006. The new timber demand study completed by the PNW Research Station was posted in March of 2006. The comment period was extended to April 30, 2007 (108 days total) due to the bad weather in Southeast Alaska, which caused several of the public meetings to be rescheduled.

Comment: Some people felt that a hard copy of the Draft EIS should have been mailed to everyone because not everyone has a computer to get online or view a CD.

Response: Nearly 1,000 copies of the Draft EIS and Proposed Forest Plan were distributed. A hard copy set of documents costs over $140 with postage. Most people found the CD met their needs and distributing CDs rather than hard copies resulted in a significant cost savings to the taxpayer. Anyone who requested a hard copy was mailed one at no charge. Hard copies were also placed in libraries across Southeast Alaska.

Comment: Some readers felt that the Draft EIS was not written very well for the lay person in that it was too long and technical.

Response: The Final EIS has been edited to fix areas that seemed to cause confusion and to be more consistent in use of terminology. Unfortunately the documents remain fairly lengthy and technical due to the complex nature of current science and natural resource management, as well as the need to stand up to intense scrutiny and legal challenge. Summary level information is, however, presented in the Comparison of Alternatives section in Chapter 2.

Comment: One comment requested that the Final EIS include a map that identifies the percent of public hearing participants that want to protect certain areas and present this information by community.

Response: This is an interesting request, but it is not possible to produce this type of map for a number of reasons. These include the fact that many people participating in the public hearings did not identify specific areas. Further, even if the Forest Service had surveyed all meeting participants, which we did not, there is no guarantee that the people who attended the public meetings are representative of their respective communities.

Restoration

Comment: A number of comments expressed support for more habitat restoration to reverse the negative impacts of timber harvest and road building. Many emphasized fixing culverts on salmon streams and deer habitat management in young growth. Many said they wanted their tax dollars spent in that manner instead of on building new roads. Some pointed out that restoration could support good jobs.

One comment stated that a substantive program needs to be put in place to promote, support, and fund a riparian and forest restoration program. The comment also recommended that this program have a dedicated funding source, such as a federal trust fund, to ensure it is actually implemented.

Another Comment recommended that the Forest add an objective for the "speedy replacement or removal" of all culverts that block fish passage to the Transportation System Riparian Standards and Guidelines (RIP2, II, H.1).

Response: The Final EIS and Final Proposed Forest Plan place more emphasis on restoration including management of young growth forest. The Tongass has prioritized the culverts that need to be replaced and many of the high priority ones have been replaced. The rate of future replacement is dependent on funding. Creating a federal trust fund would require an act of Congress and is beyond the scope of this analysis. Although the "speedy replacement or removal" of fish passage blocking culverts has not been added to the Riparian Standards and Guidelines in the Final Proposed Forest Plan, this continues to be a priority on the Tongass, but is, as noted above, dependent on funding.

Comment: One comment suggested that the Forest Plan contract restoration work associated with past practices to companies actively engaged in the forest products industry to enhance the viability of existing Southeast Alaska logging companies.

Another comment requested that the Forest Service incorporate local and Native hire provisions in its hiring practices and reduce the non-resident component of the wood products sector to less than 10 percent on Baranof Island.

Response: Contracts with the Forest Service are awarded on a competitive basis in accordance with federal contracting standards. In general, the Tongass National Forest prefers to contract with local operators, where possible. ANILCA provides for Native Alaskan hiring provisions for federal employment. The hiring practices of private sector companies are outside the scope of this Amendment process.

Schedule

Comment: Concern was expressed that some sort of "timeout" proposal might be advanced which would delay a decision on the Amendment and not really lead to any long-term solution to the issues.

Response: A decision will be made on this proposed Amendment. References to a "timeout" generally refer to how the Forest Plan might be implemented, with the intent to facilitate continued discussions about the issues, rather then delay the decision process.

Standards and Guidelines

Comment: There were many detailed comments on the wording of standards and guidelines and goals and objectives. They ranged from expressions of support or disagreement to detailed edits of the language used.

Response: These comments were carefully evaluated on an individual basis and changes were made to the Forest Plan, as appropriate. Space does not allow for an individual response to each of these detailed comments here.

Comment: One respondent commended the Forest Service for incorporating standards and guidelines that address invasive species and recommended that the new section be expanded to include discussions of Integrated Pest Management and Executive Order 13112 on invasive species.

Response: The 5-year review of the existing Forest Plan highlighted the need to update the Forest Plan to address the threat of invasive species. We believe the direction added provides the appropriate guidance to address future invasive species issues.

Comment: Several respondents discussed the importance of various resource protection standards and guidelines and the need to insure that these are mandatory requirements.

Response: The language in each Standard or Guideline indicates how mandatory the direction is. For example, "Commercial timber harvest is not permitted in this LUD" is a standard. "Salvage may be permitted…" is a guideline. Standards are mandatory while guidelines, as the name implies, provide guidance and are not mandatory. While the Forest Plan provides broad strategic direction that employees must follow, there also has to be flexibility for on the ground managers to tailor actions to meet the needs of specific locations. Managers always have the option, with appropriate documentation, to amend the Forest Plan to meet the needs of specific situations.

Comment: One respondent suggested that the definition of the estuary fringe presented in Chapter 4 of the Proposed Forest Plan include reference to a source, or sources, that identify the location of estuaries on the Tongass.

Response: Estuary is defined in the Forest Plan glossary. This definition clearly identifies where estuaries occur and provides sufficient information for the identification of these areas at the project level.

Comment: Concern was expressed about Wild and Scenic Rivers direction in the Proposed Forest Plan that appeared to restrict temporary improvements such as weirs which are fully compatible with ANILCA.

Response: Direction in the Final Proposed Forest Plan has been revised to address this concern.

Tribal Consultation

Comment: Concern was expressed that tribal governments and tribal corporations were not adequately consulted during this forest planning process.

Response: The record shows that tribal governments and tribal corporations were consulted throughout the process. The District Rangers took the lead in communicating about the Forest Plan Amendment and in organizing meetings with tribal organizations.

Comment: One comment objected to the use of Alternative 5 as a baseline for the other alternatives because they felt that the 1997 Forest Plan did not feature adequate consultation with tribal governments.

Response: Alternative 5 is used as a baseline for comparison for some of the resource analyses because it represents the current Forest Plan and is the no action alternative. The record shows that considerable tribal consultation took place in developing the existing Forest Plan. In addition, the current Amendment featured a new consultation effort to ensure that tribal issues are heard and understood.

Comment: One comment expressed the desire for native communities to build a more collaborative relationship with the Forest Service. The comment author felt that this type of relationship could help these communities be more effective in community development and better understand how to take advantage of economic opportunities. This comment specifically pertained to the city of Hydaburg.

Response: The Forest Services supports continued collaboration between the Forest Service and native communities and encourages interested parties to work with their local District Rangers.

Resource and Issue Comments

The resource and issue comments are divided into the following subsections:

- Climate and Air
- Economic and Social Environment
- Fish and Watersheds
- Geology, Soils, Karst and Caves
- Heritage and Sacred Sites
- Lands
- Minerals
- Recreation, Tourism and Scenery
- Roadless Areas and Wilderness
- Subsistence
- Timber
- Transportation and Utilities
- Wetlands
- Wildlife, Biodiversity and Plants

Climate and Air

Comment: A number of respondents were concerned about how climate change would affect the Tongass. They believe that the results of climate change will be catastrophic for the Tongass and include expansion of new species, increased blowdown, and an increase in forest fires. Several comments stated that the Draft EIS did not address the significance of the Tongass in global carbon storage. Others stated that that global warming will affect Alaska and logging old growth forest would release stored carbon into the air, further aggravating the situation. Several comments stated that there should be no logging on the Tongass until the Forest Service determines how much logging can be done without significant effects on global warming.

Response: The Draft EIS acknowledges that climate change is occurring and that it is affecting the forests of Southeast Alaska; the exact changes likely to occur over the coming decades are not certain but are expected to include warmer winters, continued severe storms, and perhaps drier summers. These factors, in turn, may lead to increased blowdown and increased insect populations, which would adversely affect existing forests and may lead to an increase in fires, although the warming trend has not resulted in these events to date, as noted in the Draft EIS. Information on the risks and uncertainty related to the effects of climate change has been added to the Final EIS. As the Draft EIS states, models available for estimating climate change are designed to predict changes on a regional level and are not detailed enough to predict changes to the Tongass. Consequently, existing models do not agree on how global warming will affect Southeast Alaska. Additional information has been added to the Final EIS dealing with carbon sequestration and climate change which incorporates recent research.

As noted in the *Climate and Air* section of the EIS, logging old-growth forest can result in additional carbon entering the atmosphere; although not all of the carbon stored on the logged area is lost. Much of the carbon stored in organic matter in the soil, as well as carbon stored in down wood, cull logs, and low-value logs left on the site, remains sequestered. Carbon stored in lumber can also be sequestered for a time, depending on how it is used. Also, even under the alternative with the highest allowed harvest level, more than three-quarters of the existing old-growth forest on the Tongass would be exempt from harvest (nearly 3.8 million acres under Alternative 7 and nearly 4.7 million acres under Alternative 1), as would nearly all non-productive forest (2.4 million acres). No carbon stored in these forests would be lost due to logging.

As the EIS states, cumulative effects on carbon sequestration depend on the amount of forest land harvested; how the harvested wood is used; the management of the non-National Forest System (NFS) land in Southeast Alaska; the amount of carbon released during harvest, processing, and transporting wood products; on-site decomposition; and the length of the rotation (the period between harvests). If the products resulting from harvest are primarily lumber and other building materials, then there is a potential that the carbon in these products would be stored for the life of the buildings, longer if the wood is recycled or placed in landfills. If the wood is used for paper products or fuel, carbon storage would be short term. Any temporary storage of carbon in lumber products may be completely offset by carbon released during and after harvest, transportation, and processing. Whether carbon sequestration would actually increase or decrease under the alternatives considered in this analysis is unknown. However, recent estimates indicate that all the carbon stored in the forests of the Tongass (including carbon stored in its soil) represents approximately one quarter of one percent of the stored carbon in forests worldwide.

Further, carbon stored in all of the world's forests represents only a small portion of the total carbon stored in land vegetation and other terrestrial biomass, in soils, in the oceans, and deep below ground. Therefore, the Final EIS concludes that, while carbon storage on the Tongass is important for many reasons, small changes in carbon sequestration on the Tongass, whether positive or negative, would have only minor effects on atmospheric carbon levels. For comparison, Leighty et al. estimate that between 6.4 and 17.2 million metric tons (0.2 to 0.6 percent) of stored carbon has been lost on the Tongass since timber harvest began in the early part of the 20th century. For comparison, approximately 4.5 million metric tons of carbon was released every day to produce electric power in the United States in 2005 (U.S. Department of Energy 2006).

Comment: Some respondents believe that the protection of old growth forest may offer the best hedge against global warming because old growth forests sequester carbon. Comments also noted that old-growth forests may have value on the carbon trading market.

Response: About 8 percent of the commercial size old growth had been harvested on the Tongass National Forest as of 2005. Leighty et al. (2006) estimate that this represents between 0.2 to 0.6 percent of stored carbon on the Tongass. If the current Forest Plan (Alternative 5) were to be implemented for the next 100 years, which would only occur if new industries and markets developed to process and utilize the wood, 82 percent of the old growth forest would still be present in 100 years time. Approximately 88 percent would remain under Alternative 1, which has the lowest harvest level, and approximately 76 percent would still be present in 100 years under Alternative 7, which has the highest harvest level.

Using the Leighty et al. estimate, this suggests that under 1 percent of the total carbon would be lost under Alterative 1 (cumulatively) and less than 2 percent (cumulatively) under Alternatives 5 and 6.

Based on Leighty et al., approximately 0.6 to 1.8 percent (cumulatively) would be lost under Alternative 7, the alternative with the highest harvest level. This is the equivalent of approximately 17 days carbon emissions from power plants in the United States (refer to the *Climate and Air* section in the Final EIS). These comparisons assume that the projected maximum harvest levels associated with these alternatives would be fully implemented over the next 100 years. However, the proposed Forest Plan Amendment would only cover the next 10 to 15 years and approximately 90 percent of the remaining old growth would still remain under all alternatives when the next Forest Plan is developed. Also, monitoring and adaptive management during the planning period may result in changes to harvest levels prior to developing a new Plan. It is also worth noting that actual harvest is likely to be lower than the projected ASQ under all of the alternatives.

Whatever carbon is lost during old growth harvest would also be partially offset by young stands which accumulate carbon as they grow. Therefore, it is unlikely that preserving all of the remaining old-growth forest on the Tongass would have a much greater effect on atmospheric carbon levels than preserving the majority of it, which would be the case under all of the alternatives. As noted in the Final EIS, all the carbon stored in the Tongass represents a small fraction of the world's stored carbon. Leighty et al. (2006) estimate that all the carbon stored in the forests of the Tongass represents approximately one quarter of one percent of the stored carbon in forests world wide. Carbon stored in the world's forests, including forest soils, represents a small portion of total global carbon storage (terrestrial, ocean, and fossil carbon pools). As noted in the Final EIS, all terrestrial sources (croplands, tundra, grasslands, savannas, etc.) store about one-twentieth of what the oceans store. Therefore, the Final EIS concludes that small changes in carbon sequestration on the Tongass, whether positive or negative, would have a minor effect on atmospheric carbon levels.

The possible future value of old-growth forests in the world carbon trading market is currently unknown and speculative at this point.

Comment: Some respondents felt that the impacts of climate change described on pages 3-98 and 3-99 of the Draft EIS are exaggerated. They believe that it is impossible to predict the effects of climate change over the 10 to 15 year life of the plan. Also, many believe trees absorb carbon as they grow and, therefore, they argue, society should support timber harvest. In addition, they note, young trees consume more carbon dioxide than old trees.

Response: As noted in the preceding comment response, the Draft EIS acknowledges that while climate change is occurring and it is affecting the forests of Southeast Alaska, the exact changes likely to occur over the coming decades are uncertain. As the Draft EIS states, models available for estimating climate change are designed to predict changes on a regional level and are not detailed enough to predict changes to the Tongass. Consequently, existing models do not agree on how global warming will affect Southeast Alaska. Additional information has been added to the Final EIS dealing with carbon sequestration and climate change which incorporates recent research.

While research confirms that young trees accumulate more carbon on a yearly basis than old trees, one must also take into account the amount of carbon already stored in old forests, including above ground vegetation, logs and organic matter on the forest floor, and organic matter in the soil. Some of this is lost when the forest is logged and the site is exposed to the sun, increasing decay rates and releasing carbon into the air. Also, carbon is released as fuel is burned during harvest, processing, and transporting of wood products. As noted in the EIS, carbon can also be stored in lumber and other building materials for the life of the buildings, longer if the wood is recycled or placed in landfills. Whether carbon sequestration would actually increase or decrease under the alternatives considered in this analysis is unknown.

Comment: Some respondents want the Forest Service to consider the impact global warming will have on yellow-cedar and end logging of this species.

Response: The EIS recognizes that the decline and mortality of yellow-cedar is one of the most widespread and important forest health problems in Southeast Alaska (see the *Forest Health* section of the Final EIS). This decline is associated with wet, poorly drained sites, and research suggests that reduced snow pack in low-elevation areas associated with a warming trend that started in the 1800s has exposed fine surface roots to freezing, which in turn kills trees. As the climate continues to warm, yellow-cedar decline is likely to continue to spread, especially in the south and east. Conversely, yellow-cedar appears to be spreading northward as climate warms, into areas that retain snow longer into the spring. Not cutting cedar trees on sites that can no longer support yellow-cedar will not change the fact that these trees are growing in areas that cannot support them. Planting yellow-cedar on suitable sites north of its current range has a reasonable prospect for success and may aid the species natural movement north.

Comment: One comment stated that the EIS should measure air quality impacts in terms of the total carbon footprint associated with cruise ships, float planes, and related commercial uses of the Wilderness. The comment stated that on calm days haze can be seen in Ketchikan, parts of Misty Fjords, and Glacier Bay National Park.

Response: This Amendment responds to the 2005 Court decision which held that the EIS and ROD for the 1997 Forest Plan had errors relating to the use of projected market demand for timber, the range of alternatives relative to market demand calculations, and cumulative effects of timber harvest activities on non-NFS lands. Measuring the total carbon footprint for cruise ships, float planes, and other commercial uses in Southeast Alaska would be difficult and time consuming and is not necessary for the analysis of the issues identified by the court. In addition, all of the action alternatives propose the same standards and guidelines with respect to cruise ships and commercial use in Wilderness. The main variables that could potentially affect the size of the carbon footprint from these activities are the number of visitors to the region and the demand for commercial recreation activities in Wilderness. The *Recreation and Tourism* section in the EIS discusses potential recreation demand, but it is not possible to project how the number of visitors to the region and demand for Wilderness recreation would be affected by each alternative with the type of precision required to estimate differences in the resulting “carbon footprint.”

We were unable to find information on carbon footprint for cruise ships, float planes, or other commercial uses in Southeast Alaska in the literature, but we are aware of studies underway to identify cruise ship emissions. No results for carbon emissions into the atmosphere have been reported to date specific to the cruise ship business in Southeast Alaska to our knowledge. However, we did find a general estimate of CO_2 released per passenger mile (0.43 kg) (http://www.responsibletravel.com/Copy/Copy100858.htm). A rough extrapolation of this, based on the estimated number of cruise ship passengers visiting the Southeast Alaska (948,226 in 2005), results in an estimated total of 78,000 metric tons of carbon released in 2005 (this assumes each cruise was 7 days and ships averaged 100 miles per day travel, including port stays). The portion of this that may have been released in or near wilderness areas is unknown. Please note that this is a very rough estimate. For comparison, as noted in response to one of the preceding comments, approximately 4.5 million metric tons of carbon were released every day to produce electric power in the United States in 2005 (U.S. Department of Energy 2006).

As noted in the Draft EIS, the air quality for all of Southeast Alaska, except for the Juneau area, is rated as good by EPA. Air quality in the Juneau area has improved and has met EPA’s air quality standards in recent years, as noted in the Draft EIS. Also, as noted in the Draft EIS, smoke from fires in western Canada sometimes crosses into the Southeast Alaskan air shed, causing haze.

Comment: Some respondents stated that although climate models predict warmer winter temperatures, they also predict more snow at higher elevations. One comment noted that Juday et al. (1998; 41), for example, state there is a strong possibility of heavy snow at high elevations. They respondents expressed concern that in some years there will also be more snow in low-elevation areas and note that the deer model does not take this into account.

Response: It is certainly possible that there will be heavy snowfall in some winters at low elevation, just as it is possible that, with global warming, there will be less snow in low-elevation areas in most winters. Weather models are not able to accurately predict next year's snowfall, much less snow levels over the next several decades. However, Juday et al (1998) predict ("with some confidence") low snow accumulations in most low-elevation forest in Southeast Alaska. Concerns about the deer model and severe winters are discussed in the Wildlife, Biodiversity and Plants section of this appendix under Deer.

Comment: One comment states that both the HAFCM2SUL and the CGCM1 climate models predict a 30 percent increase in the mean seasonal severity rating for fires in Southeast Alaska by 2060. The comment notes that Dale, Juday, and other scientists predict an increased risk from insects and disease. The comment also states that increased rain will lead to more landslides, adversely affecting water quality and fisheries in Southeast Alaska. The comment notes that Salathe (2006) suggests that a 15 percent increase in precipitation over the whole of Southeast Alaska is indicated and the comment states that the resulting increase in soil moisture would increase likelihoods of windthrow, stem snap, and mass wasting.

Response: Our reading of the HAFCM2SUL and the CGCM1 models indicate that they predict a 10 to 30 percent increase in the fire severity rating, depending on the model. In any case, a 30 percent increase in almost no fires (the current condition) would still result in little damage due to fires. As noted in the Final EIS, Berman et al. (1999) state that it is difficult to predict the magnitude of area likely to be burned in a region with no historic fire record, but they believe that most fires would be small and of low intensity. They suggest a scenario in which 5,000 acres might burn over a period of decades, an average of perhaps 100 acres a year in an ecosystem that includes over 10 million acres of forest. Juday et al. (1998) also suggest that the effects of fires on resources are likely to be low.

There is no evidence that there has been increased damage from windthrow or insects in the last several years, as noted in the Draft EIS. There was a big up-swing in insect damage in the 1990s but this has subsided. We can expect other periods of increased insect activity, as insect population cycles ebb and flow. This is a natural part of the ecosystem. That said, it is likely that there will be some additional risk to forests from both insects and disease as the climate continues to warm. However, there is little evidence of increased insect, disease, or blowdown during this decade even though the climate has warmed considerably and gale-force storms have increased, as discussed in the Draft EIS. Juday et al. (1998), for example, suggest that the increase in gale force winds could result in increased blowdown. However, they also state that this had not occurred as of their study, nor did the 2006 survey report such an increase, despite the large increase in storm events over the last several decades. Periodic catastrophic windthrow has long been a factor in Southeast Alaska and can be expected to continue to be.

The Draft EIS notes that most studies predict wetter weather in Southeast Alaska over the coming decades. As noted in the comment, some researchers believe that increased rain could lead to more landslides. This in turn, could affect water quality and fish habitat. There's quite a lot of research about rain and snowmelt-driven landslide events (particularly in Washington and Oregon). Whether more rain would mean more landslides in Southeast Alaska would depend on local conditions at the time of the event, such as the rain characteristics (intensity, duration), the soil conditions (degree of saturation, pore pressure), the vegetation characteristics (vegetation cover, root strength) all of which could be affected by climate change as well as other factors that might not be so directly affected by climate change (including slope angle and any changes in lateral support, loading, or vibrations). Until climate models at the sub-regional scale include these factors it will be hard to quantify the risk.

The Salathe (2006) paper referenced in the comment finds "greater precipitation over the North Cascades and extending southward along the Cascades. Increases in precipitation are also found for the Idaho Rockies…" We did not see a prediction specific to Southeast Alaska.

Specific concerns regarding the potential effects of climate change on wildlife are addressed in the Wildlife, Biodiversity and Plants section of this appendix

Comment: Some respondents believe that the forests of the future will need to be resilient to novel conditions presented by climate change. They stated that old-growth forests, having survived fires, droughts, and insect and disease outbreaks of the past, have shown themselves to be resilient to change. Once comment cited recent research in California that indicates that old growth is more resilient to fires than plantations and fires are expected to increase in the future climate which is expected to have drier conditions. One comment stated that replacing old growth forest with young stands would expose the forest to increased risk of fire, insects, and disease, and concluded that, therefore, the Forest Service should avoid cutting old growth.

Response: The old-growth trees present today began life in the cooler climate of the little ice age, which began about 700 years ago and ended about 150 years ago. They have not endured fire to any notable extent, nor prolonged drought. Southeast Alaska has a cool, wet climate even in the warmest, driest years. This is a very different situation than in California, where tree species present in old-growth forests have evolved along with fire and drought and have developed coping mechanisms, such as thick bark, as a protection from periodic fires. There is little reason to think that old Sitka spruce or western hemlock trees would be better suited to a warmer climate than young trees of the same species, nor could one make a strong case for the opposite.

If the climate does get warmer and drier (some predict that it will get warmer and wetter) then hemlock and spruce trees would be less well suited to Southeast Alaska than they were during the past cool period. The fact that thick-barked, old-growth pine and Douglas fir trees in California are more resistant to fire than young trees says little about the resilience to fire of thin-barked, old-growth hemlock and spruce trees. Also, as noted in one of the preceding responses, the predicted 10 to 30 percent increase in the fire severity rating would still result in few fires and little resource damage. A more realistic threat to forest health comes from insects. Experience indicates that insect outbreaks have had a greater effect on old forests than on young ones (refer to the *Forest Health* section of the EIS).

Comment: One comment stated that it is important to preserve northern forests, which preserve 50 percent of Earth's carbon, and also noted that cutting trees will lead to more fires.

Response: The great majority of the earth's carbon is in the oceans as discussed in the *Climate and Air* section of the Final EIS. Also, the risk of fire in Southeast Alaska is very small, as discussed in the Final EIS.

Comment: Some respondents believe that the effects of climate change on values/resources should be given the same consideration as timber harvest. They state that just because there is uncertainty that does not mean the EIS does not have to analyze the possible effects, just as it does with timber demand, which is also uncertain. They believe the EIS should analyze the range of possible effects that climate change will have on values and/or resources and on achieving the desired future condition for these resources.

Response: Information that discusses the range of effects that climate change may have on achieving the desired future condition for various resources has been added to the appropriate sections in the Final EIS.

Comment: One comment stated that the Forest Service should lead by example and "enable ecosystems to adapt to climate change" by applying the principles outlined in Forest Service publications. The comment also stated that the Forest Service should analyze 11 studies that were listed in the comment.

Response: The Tongass planning team reviewed the cited studies, as well as many other studies on climate change. Some of the studies recommended in the comment are applicable to Southeast Alaska and the Tongass National Forest (e.g., Berman et al. 1999, Juday et al. 1998) and information from these studies was added to the Final EIS. Others are very broad based, general discussions on what may happen, often in other distant parts of the U.S. (i.e., effects on trout in the southeast U.S., fire risks in the western continental U.S., carbon dioxide [CO_2] effects on growth rates in the continental U.S.). The planning team reviewed this literature, with guidance from scientists at the PNW Research Station, and sought to use the most appropriate studies to show the range of possible outcomes for the Final EIS. We favored local studies where available. Some of the studies referenced in the comment had limited applicability to the Tongass. For example, the comment recommended that we consider Pratsad and Iverson (1999), which considers the effect climate change will have on 80 tree species in Eastern North America as an example of how we should model changes on the Tongass. However, this study deals with trees on a subcontinent-level, and in a less complicated region geographically. By comparison, the Tongass is about the size of West Virginia and is made up of a series of islands and a narrow strip on the mainland bordered by tall mountains and glaciers to the north and east and by the Pacific Ocean to the west. Consequently, it is difficult to predict changes using existing models designed to predict changes on a continent or subcontinent level.

As noted in the Final EIS, models are based on predictions for large regions and do not agree on exactly what is likely to happen in local areas such as the Tongass beyond the likelihood that the climate will be warmer. Researchers have modeled changes in the range of species at the Alaska regional scale. They estimated that the boreal forest will likely move approximately 100 miles north, coniferous and mixed forest would advance into the boreal zone, and the southern coastal forests are likely to expand westward (various studies cited in Parson et al. 2001). Studies also predict that trees in Southeast Alaska will expand their range upward into higher elevations and both yellow-cedar and red cedar will expand their range northward. As one of the papers cited in the comment (Hansen et al. 2001) notes, topographic barriers between Canada and Southeast Alaska are likely to limit the northward expansion of species into Southeast Alaska, therefore we do not anticipate species such as Douglas-fir migrating to the Tongass in the foreseeable future.

The Aber et al. (2001) paper cited in the comment discusses the effects of higher CO_2 on tree growth and illustrates the difficulties involved in trying to estimate the effects of global warming on the Tongass National Forest. While their focus is on the continental United States rather than on Alaska, Aber et al. demonstrate the problem of applying general theory to specific areas. There is research indicating the higher CO_2 levels driving climate change may increase the rate of photosynthesis and therefore tree growth, at least in the short term. However, this and other studies indicate that this would only occur if no other factor is limiting, such as water or nutrients. Whether water will be limiting in Southeast Alaska is unknown. Some models indicate a 10 percent reduction in summer rain across the Tongass but others do not. This leaves us without much certainty as to whether growth rates will increase. All we can really take from this, and similar studies, is a note of caution; therefore, the Final EIS does not predict increased tree growth for the Tongass, though it acknowledges the possibility. Increased tree growth, if it does occur, could increase carbon sequestration and future timber production, which in turn could lead to shorter recovery rates for disturbed habitats.

Comment: Several comments stated that the Forest Service should conduct research on greenhouse gases and carbon dioxide and identify how logging and re-growth change the carbon budget on the Tongass.

Response: Estimates of the amount of carbon stored in existing forests and the amount lost as a result of harvest are included in the Final EIS, as is a discussion of the problems encountered in attempting to estimate the amount of carbon released due to harvest. The PNW Research Station continues to conduct research on global warming.

Comment: One comment expressed concern that timber harvest results in air pollution which causes asthma and lung problems.

Response: As discussed in the *Climate and Air* Section in the EIS, air quality is good on the Tongass and timber harvest has little effect on air quality in the region. In many other regions, logged areas are broadcast burned following harvest to dispose of logging slash and this can adversely affect air quality. Broadcast burning is not used on the Tongass.

Comment: One comment pointed out that the construction of interconnecting electric power lines would reduce air pollution from diesel generators, and result in a reduction in CO_2 emissions.

Response: Information on this subject has been added to the *Climate and Air* section of the Final EIS. The alternatives would not affect power line construction; all alternatives propose the same Transportation and Utility System LUDs.

Economic and Social Environment

The Economic and Social Environment comment and response subsection is divided into the following categories:

- Timber Demand
- Regional Economy
- Economic Efficiency Analysis
- Tongass National Forest Budget
- Payments to the State
- Communities

Timber Demand

Comment: Some respondents felt that the model used by the PNW Research Station to determine timber demand was obsolete. In particular, they felt that using a model built around exports to the Pacific Rim was a fatal flaw now that domestic markets are the primary destination for Tongass timber. They note that the model does not include a single parameter to account for changes in domestic markets.

Response: Brackley and Haynes (in press) state that "the existing model is a robust system that remains a valid approach to model demand for Tongass timber because of the limited data on lumber shipments and values and production costs." They go on to explain that Alaska producers are sawing lumber products that are, on average, better quality and enter higher priced markets, than lumber manufacturers are producing in the western Pacific states and in Canada. These high quality products have similar prices in domestic and foreign markets. Using historic data with scenario assumptions to model movement of these products in both domestic and foreign markets is a valid approach.

The method to project timber harvests and output in Alaska followed by Brackley et al. (2006a) is essentially the same as that described in publications about previous estimates of Alaska timber demand by Haynes and Brooks (1990), Brooks and Haynes (1990), Brooks and Haynes (1994), and Brooks and Haynes (1997). The method begins by estimating Alaska forest products output, by product, followed by calculating the raw material requirements necessary to support this production, using explicit product recovery and conversion factors. The total raw material requirement (the total derived demand for timber) is a combined projection of timber harvest from private ownership, from National Forests, and from non-

National Forest public owners. The projected National Forest timber demand is the quantity of timber required to satisfy projected derived demand given harvest by other owners, and given explicit assumptions about markets and implicit assumptions about prices.

Brackley et al. (2006a) assembled historic data that describe relevant components of the Alaska forest sector and calculated possible future wood needs by using an analysis of trends in factors that influence harvests. A historic period of about 40 years (1965 to 2004) was used as a basis for a projection of 20 years (2005 to 2025), to avoid emphasis on short-term cycles. They used information about US exports to Japan, and Japanese import data, as a benchmark for the historic data, as such exports represented, until very recently, the vast majority of sawn wood production from Southeast Alaska.

Data about recent domestic end markets for sawn products from Southeast Alaska has been available since about 2000. The data on domestic end markets is difficult to verify. One major question is how much of the product shipped to the Pacific Northwest is trans-shipped. Trans-shipments are products that are shipped into foreign markets from a different customs district than the one in which they were manufactured. In the case of Southeast Alaska, lumber manufactured in Alaska is apparently being shipped to foreign markets from the Seattle customs district, making it difficult to track many of the very recent end markets and subsequent demand for manufactured products from Alaska.

Other data used in the Brackley et al. (2006a) analysis includes log sources from all ownerships in Southeast Alaska, log and chip shipments out of Alaska to various destinations from all owners, harvest by owner, the Alaska market share for manufactured products in North America, and the North American market share in Japan. Brackley et al. (2006a) allocated their projections of total derived demand to foreign export markets (17 percent) and domestic markets (83 percent). They used information from Resource Planning Act (RPA) projections and assessments of future demand to estimate increases in derived demand in the future, allocated between domestic and foreign markets.

Predicting demand for federal timber in the wood products market in Southeast Alaska is difficult, due to the relatively small size of the market, the kinds of data available, and the structure of land ownership in the region. The structure of the model used by Brackley et al (2006a) makes it difficult to assess changes in domestic markets. This will need to be addressed in future demand predictions for Southeast Alaska, but gathering historic data that can be used in such a trend analysis for recent market shifts is problematic. It became clear from data reported by Kilborn et al. (2004) that shipments of manufactured wood products from Alaska were shifting from foreign to domestic destinations by 2000, and the continued significance of the domestic market through 2004 is illustrated by data reported by Brackley et al. (2006b). However, checking this data against data sources for domestic shipments and foreign exports is difficult at present, because of lags in reporting and the issue of transshipments. Data used in the Brackley et al. (2006a) model was cross-checked by the authors to ensure its reliability. It will take more research to assess if the end market information reported by Kilborn et al. (2004) and Brackley et al. (2006b) can be reconciled with other sources of data, such as the Harmonized Trade Code information, so that verifiable domestic shipment data can be used in future Southeast Alaska wood products demand assessments.

Comment: Some respondents felt that the PNW Research Station demand report was overly optimistic and did not accurately account for the challenges faced by producers in Alaska related to the competitive disadvantages of higher harvesting, transportation, and manufacturing costs. They pointed out that in most years the existing industry has been operating at less than 50 percent of the installed mill capacity. They felt that new industry investments, associated with the higher demand scenarios, were unlikely to occur. Some comments stated that the harvest level for the past few years represented the actual demand.

Response: Brackley and Haynes (in press) state that “current production levels and shipment patterns in Southeast Alaska demonstrate how the industry has transitioned to operate in current market opportunities”. They go on by saying that shifts to “higher proportions of shop lumber, larger sizes of dimension lumber, heavy timbers, and cants should give Alaska producers an opportunity to supply products of relatively higher value to both domestic and export markets."

Brackley et al. (2006a) selected four scenarios they deemed reasonable and possible, given their assumptions. The Limited Lumber Production and the Expanded Lumber Production scenarios assume the wood processing industry in Southeast Alaska is focused only on processing of sawlogs. The primary difference between these two scenarios is the assumption that Alaska will increase its market share in the North American export market from 0.39 percent to 1.14 percent in the Expanded Lumber scenario, while the Limited Lumber scenario maintains the same market share for Alaska products in the North American market as a whole. The Medium Integrated Industry and High Integrated Industry scenarios both assume one or more chip and utility processing facilities will be added to the Southeast wood processing industry. These two scenarios assume an increase in Pacific Rim lumber imports, but not to the extent assumed in the first two scenarios. These two integrated industry scenarios also assume varying increases in the Alaska share of the North American export market. The Medium Integrated scenario assumes markets for chip and/or utility material will increase in 2008, while the High Integrated scenario assumes markets for chips and/or utility material will increase in both 2008 and again in 2012. Although Brackley et al. (2006a) assumed these markets would be the result of processing facilities built in Alaska, any market stimulation that results in higher demand for chip or utility material would have the same result. The recent policy change regarding appraisal of lower grade material for shipment to the lower 48 states could have a similar effect to building a processing facility for lower grade material, in terms of demand stimulation.

Comment: Some respondents felt that demand scenarios should not have been based upon non-existent facilities. They noted that the demand study prepared by Brooks and Haynes (1997) did not count potential demand from proposed facilities.

Response: Brooks and Haynes (1997) had scenarios labeled high, medium, and low. They chose not to go into detail in their discussion about how these demand levels might be achieved, simply leaving the discussion more general. Brackley et al. (2006a) chose to discuss how their scenarios might look "on the ground", to give an idea to the reader how demand might actually be stimulated under their assumptions in their model. The structure of the model itself, however, is simply driven by changes in relative market shares based on a number of assumptions, as discussed in response to the preceding comments in this section. Brackley et al. based this discussion of how changes in demand might take place based on efforts to plan and build various facilities in Southeast Alaska that would utilize lower grade material and have been under discussion for some time. However, as mentioned above, the demand stimulation could also take place as a result of other events, such as policy changes in timber sale appraisals.

Comment: Some respondents questioned why a timber demand scenario was not developed for a declining timber demand. They cite studies that indicate the possibility of the United States playing a smaller role in global wood products markets in the future.

Response: Brackley et al. (2006a) recognized that the US is a net importer of timber. A mill in Alaska has the option to ship products to traditional export markets (Japan), emerging new markets, or the lower 48 states. Demand for wood products is global in nature and increasing amounts of wood products are being imported into the United States. Alaska products constitute a small proportion of the total US market; very small shifts in how much of the US market Alaska supplies can mean a big change in Alaska.

Brackley and Haynes (in press) state that several short and long-term changes point to an increase in demand for wood products from all sources, including Alaska. These changes include a slowing in lumber production in sawmills in western Canada, in addition to longer-term factors, such as increased interest in renewable energy applications and a projected steady increase in US population and a concurrent growth in demand for softwood products. Brackley and Haynes state that the probability of a future decrease in demand for lumber from all Pacific Rim markets is virtually zero. In fact, they argue that projected consumption in domestic markets alone will increase substantially. Therefore, there was no compelling reason for the Brackley et al. study to include a scenario showing demand falling, which would be contrary to the best scientific information available.

Estimated demand for Alaska sawn products declined considerably between Brooks and Haynes (1997) and Brackley et al. (2006a). The lowest projection of derived demand for sawn products from Alaska in Brooks and Haynes (1997) for the period 2003 to 2007 was 130 million board feet (MMBF). The lowest projection in Brackley et al. (2006a) for the same period was 30 MMBF. These differences were due to changing assumptions from one projection to another, and shifts in the structure of the industry as it adjusted after the end of the long-term contracts. Also see Chapter 2 of the Final EIS, Alternatives Considered but not in Detail.

Comment: Some comments stated that even when supplemented by state and private wood Alternatives 1 through 6 would not produce enough wood to meet market demand. Others argued that Forest Service demand studies have not adequately recognized the value of 100 percent wood utilization and the critical need to restore an integrated wood products industry to Southeast Alaska. Some stated that only Alternative 7 would produce enough timber (360 MMBF per year) to supply a fully integrated timber industry.

Response: The Medium Integrated Industry (Scenario 3) and High Integrated Industry (Scenario 4) scenarios in Brackley et al. (2006a) both assume one or more chip and utility processing facilities would be added to the Southeast wood processing industry, creating an integrated industry. The timber demand analysis presented in the *Economic and Social Environment* section of the Final EIS indicates that both Alternatives 4 and 7 would provide sufficient volume to meet projected demand under Scenario 4 in the second decade following plan implementation.

Comment: Some comments were concerned that as designed none of the alternatives provide enough timber to sustain a fully integrated timber industry (Brackley et al. Scenario 4). Alternative 7 has one-third of its harvest in Scenic Viewshed and Modified Landscape LUDs, which would not result in economic timber sales. Some stated that a total of 1.5 million acres of commercial forest land is required to allow economic timber harvest and provide annual harvest levels of 360 MMBF (or some said 370 MMBF) per year. Others commented that the Forest can harvest 360 MMBF per year using only 25 percent of the forest land.

Response: The range of alternatives evaluated in the EIS provides sufficient volume to meet the four demand scenarios, when timber from state and private land is considered. One assumption is that, if an integrated industry does develop, lower-grade logs from private land would be available for local use, for example, in an MDF plant. These logs are currently exported or shipped to the lower 48 states because there is no local market for them. As noted in the preceding comment response, the timber demand analysis presented in the *Economic and Social Environment* section of the Final EIS indicates that both Alternatives 4 and 7 would provide sufficient volume to meet projected demand under Scenario 4 in the second decade following plan implementation.

Some areas on the Tongass are designated as Scenic Viewshed or Modified Landscape because the Forest Service is required to manage for multiple use. The conservation strategy requires managing some lands outside of the Wilderness for wildlife (e.g., beach fringe, OGRs). Managing scenic areas as Scenic Viewshed protects the scenery resource while making some timber available from these areas. Many other areas are important for recreation and therefore are managed as either Scenic Viewshed or Modified Landscape. This protects these resources while providing some timber. The bulk of the timber harvest under all the alternatives comes from areas classified as Timber Production; these are areas that allow more intensive timber harvest, while still protecting other resources, such as fish and water quality through stream buffers and other standards and guidelines.

Comment: Some respondents felt that the PNW Research Station demand study did not adequately take into account the lack of a reliable and economic supply of timber. They argued that poor timber sale design is a greater problem than poor markets. A number of comments stated that industry would respond to a reliable, economic supply of timber with investments to build a competitive integrated industry.

Response: The PNW Research Station has published several demand studies conducted in support of Tongass Land Management planning efforts (Brooks and Haynes 1990, 1994, 1997; Brackley et al. 2006a). These studies estimate derived demand for timber in Southeast Alaska. They do not address supply issues. The supply of timber from the Tongass National Forest is determined by two main factors. The first is the volume of timber offered for sale by the Forest Service. In April 2000, procedures to determine the estimated supply needed were published in 'Responding to the Market Demand for Tongass Timber' (Morse 2000). These procedures to estimate the timber offer target (supply) incorporate the demand numbers from the PNW Research Station studies as an input into a spreadsheet. The procedures developed by Morse (2000) to estimate the annual sale offering targets from the Tongass National Forest address the uncertainty associated with forecasting market conditions, considering the continuing transformation of the timber industry and the inability of the Forest Service to respond quickly to market fluctuations due to the time it takes to prepare timber for sale.

The second factor affecting timber supply is the cost of harvesting and delivering wood to its respective intermediate markets: mills in the case of locally processed material, and ports in the case of log exports. Although a significant issue, reduced volume offered for sale by the Tongass National Forest is not the sole reason for recent harvest declines. Rather than merely securing volume, the challenge facing Tongass National Forest timber purchasers is being able to make a profit from new sales volume and volumes currently under contract.

Profitability for Tongass National Forest timber can be affected by (1) the combination of valuable materials versus logging costs in a given timber sale, (2) market options for lower grade material coming off the Forest, and (3) prices for Southeast Alaskan premium species and grades. Limited market options for lower grade material is at least partially the result of the closure of the region's two pulp mills in the 1990s, though the removal and sale of low grade and utility logs had been a challenge for independent operators in low markets prior to the closures. Many contracts now allow the option of leaving utility stumpage in the woods, but current market conditions are still challenging profitability.

Planning the timber program requires more than just pure economic factors. To account for delays in timber sale preparation, administrative appeals, and/or litigation, sufficient contingent volume must be included in the annual timber sale program to account for realistic fall-downs. Budget and organizational constraints limit the extent to which the Forest Service can respond to economic cycles and the associated fluctuations in timber demand. All of these factors must be considered in evaluating the market demand for timber and setting timber offerings. In the final analysis, planning the timber sale program is an exercise in professional judgment.

The current status of the timber industry in Southeast Alaska is discussed in the *Economic and Social Environment* section of the EIS and includes the following summary of the difficulties involved in accurately projecting future demand.

> Accurately projecting future demand is difficult and cannot be considered an exact science. Market demand for Southeast Alaska timber and wood products depends upon numerous difficult to predict factors, including changes in technology, growth and exchange rates in key markets, changes in consumer tastes and preferences, as well as developments in other producing regions whose products compete with those of Alaska. While demand is difficult to predict, industry relies on a stable timber supply in order to conduct long-term business planning.

The section also states specifically with respect to Brackley et al.'s Scenario 1 that: "The current status is believed to be largely the result of supply limitations and not necessarily related to market demand."

Comment: One comment stated that the estimate of installed capacity of 261 MMBF identified on page 2-47 of the Draft EIS is low. The manufacturers of the mill equipment estimate that the "active, installed capacity" is 370 MMBF.

Response: The active processing capacity of the timber industry in Southeast Alaska in 2004 and 2005 was 261 MMBF, as stated in the Draft EIS. This estimate is from the detailed mill surveys conducted in those years (Brackley et al. 2006b, Juneau Economic Development Council 2006). This, as stated on page 2-47, was the estimated active installed processing capacity in 2005. Total estimated processing capacity for those years was 376 MMBF. The difference is the capacity of three mills that were installed but not active in 2004 or 2005. These mills were: KPC/Annette Island Hemlock Mill (70 MMBF), Gateway Forest Products Veneer Mill (30 MMBF), and Kasaan Mountain Lumber & Log (15 MMBF). This is noted in Table 3.22-5 in the Draft EIS. It may also be noted that the analysis summarized on page 2-47 uses both the active (261 MMBF) and total (376 MMBF) processing capacities as benchmarks for evaluation.

The mill capacity discussion presented in the Economic and Social Environment section of the Draft and Final EIS documents has been updated in the Final EIS to include the findings of the 2006 mill survey, which was completed following publication of the Draft EIS (Juneau Economic Development Council 2006). There was a net decline of 5.5 MMBF in total and active processing capacity in 2006. Northern Star Cedar in Thorne Bay sold equipment capable of processing 8 MMBF and Icy Straits Lumber in Hoonah added a linebar resaw and 2.5 MMBF of capacity (Juneau Economic Development Council 2007). The installed capacity benchmarks used for evaluation of the alternatives have been updated accordingly in the Final EIS.

Comment: One comment stated that the installed capacity figures used in the Draft EIS appeared to substantially overstate existing mill capacity. The comment noted that the figures for the mills in Hoonah, for example, appeared to be 6 to 10 times their actual processing levels.

Response: The installed capacity figures included in the Draft EIS are from the annual mill surveys conducted in 2004 and 2005 (Table 3.22-5). As explained in the Draft EIS, installed capacity is the volume of material that the mill could process in 500, 8-hour shifts. This is not the necessarily the same as the amount actually processed in any given year. The actual amounts processed in 2004 and 2005 are also shown by facility in Table 3.22-5. Actual utilization (or actual processing levels) for the sawmills in Hoonah were, as noted in the comment, substantially below the installed capacity in 2004 and 2006 (see Table 3.22-5). This table has been updated in the Final EIS to include the results of the 2006 mill survey (Juneau Economic Development Council 2007).

Comment: One comment questioned whether the timber demand projections used in the EIS considered peak oil concepts and the projected increase in oil prices, which will negatively affect the competitiveness of the timber industry in Southeast Alaska.

Response: The methodology used to develop the PNW Research Station demand projections is explained in Brackley et al. (2006a), with additional information provided in an addendum prepared in response to comments on the Draft EIS (Brackley and Haynes, in press).

Comment: One respondent asked if Brackley et al. considered a potential increase in demand from the lower 48 states.

Response: The Brackley et al. (2006) study included the assumption of increasing demand in domestic markets. Brackley and Haynes (in press) add further detail to this assumption. Populations in the US are projected to continue to rise in the future, along with demand.

Comment: One comment stated that there is too much wood fiber on the market from domestic and foreign producers and the glut will continue for decades. They believe that the building industry doesn't need or want additional wood from the Tongass.

Response: Brackley and Haynes (in press) argue that Alaska producers have a unique advantage over all other manufacturers in the Pacific Northwest in their access to high quality wood. Alaska producers compete in different market segments with higher value products, on average, with better visual and strength characteristics. Demand for this high quality wood is strong and consistent.

The Forest Service uses a scientific process, Morse 2000, to determine timber sale offer levels to seek to meet annual demand. Among other things it takes into consideration volume under contract and past harvest to help determine what the current demand is for timber.

Comment: The alternatives in the Draft EIS are based on the same faulty logic as those alternatives evaluated in the 1997 EIS. TTRA requires that the Forest Service seek to meet market demand. Market demand for the past several years has been about 50 MMBF and, therefore, only Alternative 1 is consistent with TTRA and the Court order.

Response: Timber harvest in what economists call an "imperfect market", with one major seller and with supply limitations, does not equal demand. In other words, recent harvest levels on the Tongass National Forest do not equal demand.

The basic approach of all the PNW Research Station demand studies over the last 17 years has been to derive the demand for timber from the Tongass from estimates of demand for the end products manufactured from Tongass timber in the markets in which those products are sold. This approach makes it possible to estimate the demand that would exist in the absence of the considerable constraints currently placed on the supply of timber. Examples of such constraints include appeals and litigation, difficulties in preparing sales with positive appraisals, legislation unique to the Tongass that disallows timber purchasers from requesting sales with negative appraisals be offered, and funding levels. In addition, the limited interstate shipment policy has only recently made it possible for sales to be appraised on the assumption that low-grade and small diameter material will be sold in continental US markets, which is expected to enable more sales to appraise positive, and allow them to be offered, than was the case before the policy was adopted. Finally, the Brackley et al. report mentions other developments such as biofuels that could substantially increase future demand, even if the current model cannot quantify such effects.

For all these reasons, we believe the level of timber harvested on the Tongass in recent years is not a good basis for estimating market demand for the next decade or two.

Comment: One comment stated that the following harvest levels represent important thresholds for the timber industry:

- **83.5 MMBF is the bare minimum needed to keep Southeast Alaska mills in operation over the next one to two years, while the supply of timber from the Tongass is increased. This would allow short-term, single-shift operation of the existing mills.**
- **167.5 MMBF per year is needed to allow existing mills to operate two shifts daily and provide 30 MMBF for development of a new facility that would use low-value timber.**
- **231.7 MMBF is needed for the existing mills to operate at full capacity (three shifts daily) and provide 30 MMBF for a facility that would use low value timber.**

This, they note, needs to be economically feasible timber, not the ASQ, which has historically been much higher than the economically feasible level.

Response: The above volumes are broadly similar to the minimum timber volumes required by various processing facilities that are identified in Table 3.22-17 in the EIS. These volumes are used as one set of benchmarks against which the projected NIC I component of the ASQ available under each alternative is compared.

Comment: One comment stated that the analysis prepared for the Southeast Conference and referenced in the Draft EIS—"Timber Markets Update and Analysis of an Integrated Southeast Alaska Forest Products Industry" (McDowell Group et al. 2004)—has been updated. This updated version should be used in the Final EIS. The Southeast Conference has also commissioned another study—"Level of Harvest Capability Required to Support an Integrated Forest Products Industry in Southeast Alaska" (Cascade Appraisal Services, Inc. 2007). The results of this study should also be included in the Final EIS.

Response: The industry capacity reports referenced in the above comment have been reviewed and the updated McDowell Group study is cited in the Final EIS. These reports both included comments on the Draft EIS. These comments are summarized and responded to in this appendix.

Comment: One comment stated that the analysis should not use market demand or installed capacity to determine how much of the Tongass should be cut. Timber should be harvested on a sustained yield basis.

Response: The EIS used market demand to identify the range of alternatives to be evaluated in the Draft EIS because Key Issue 2 for the EIS responds to the requirement under TTRA that the Forest Service seek to meet market demand for timber in Southeast Alaska. Installed capacity is not used to determine harvest levels, but as one benchmark against which the projected ASQ available under each alternative can be compared. All alternatives propose that timber harvest be conducted on a sustainable basis.

Comment: One comment stated that the Morse method used by the Forest Service to establish annual timber sale objectives and meet demand for Tongass timber on an annual basis has a number of shortcomings including a low mill capacity estimate, a "contrived" capacity utilization rate, and unrealistic estimates of non-federal sources of timber. The same comment author also points out that the Forest Service is not meeting its goal of having an approximate three-year supply of timber under contract. The proposed sales identified in the Forest Service's current 5-year plan added to the existing volume under demand would not provide three years worth of supply for an annual harvest of 150 MMBF, let alone the 350 MMBF industry representatives believe is necessary for an integrated industry.

Response: The Morse methodology is referenced in the Draft EIS, but is not part of the analysis and has no bearing on the decision making process. As a result, questions surrounding this methodology are beyond the scope of this analysis. This methodology is, however, discussed in Appendix G.

The Draft EIS identifies that the goal of the Forest Service is to have an approximate three-year supply of timber under contract, as cited in the above comment. However, in the same paragraph, the text explains that: "(i)n recent years the Forest Service has not been able to achieve a three-year supply under contract, mostly due to litigation and administrative policy changes (i.e., Roadless Area decisions)." This discussion has been expanded in the Final EIS.

Comment: One comment pointed out that the Draft EIS (page 3-424) incorrectly references a Juneau EDC/Tongass Futures Roundtable demand projection of 248 to 268 MMBF. The comment author points out that the Tongass Futures Roundtable has not developed any demand projections.

Response: This discussion has been revised in the Final EIS and the reference to the Tongass Futures Roundtable estimate has been deleted. This projection and the correct source are presented in Table 3.22-17 in the Final EIS. The correct source is as follows: Estimates developed by the Forest Service based on McDowell Group et al (2004), Brackley et al. (2006b), and the Juneau Economic Development Council (2006) with updates by Southeast Alaska sawmills.

Comment: One comment stated that the mill capacities presented in Table 3.22-17 in the Draft EIS are incorrect and represent "some very temporary, rough estimates of how much timber the currently operating mills needed to survive one year." The comment then refers the Forest Service to the 2005 Mill Capacity and Utilization Study for actual capacity information.

Response: The estimates presented in Table 3.22-17 in the Draft EIS are, as stated in the title to the table, the minimum timber volumes required by various processing facilities. The capacities identified in the 2005 Mill Capacity and Utilization Study are presented in Table 3.22-5 in the Draft EIS. A 2006 Mill Capacity and Utilization Study was completed between the publication of the Draft and Final EIS documents. The results of the 2006 study have been incorporated in the Final EIS (Juneau Economic Development Council 2007).

Comment: One comment stated that the minimum volumes identified in Table 3.22-17 are not "additive." An MDF facility needs 80 to 100 MBF to operate but this volume needs to be utility logs and sawmill chips only. If an MDF facility had to rely on higher priced sawlogs for its supply it could not be competitive with MDF facilities located elsewhere. The comment author, therefore, concludes that a harvest level of approximately 360 MMBF would be required to supply an MDF facility. Further, different facilities require different types of logs.

Response: Table 3.22-17 in the Draft EIS identifies the minimum volumes required by various processing facilities. These volumes are used in the following analysis by alternative. The analysis does not simply assume that total demand is 248 to 268 MMBF, although this is one measure that could be employed. Rather, the analysis evaluates whether each alternative would meet all or part of the estimated minimum requirements and discusses ways in which these estimated demand levels could be met based on the average timber harvest composition. The average timber harvest composition used in this analysis is estimated based on the average composition of recent sales on the Tongass (see Table 3.22-18 in the Final EIS).

This alternative-by-alternative analysis also uses the maximum annual average harvest levels (NIC I component of the ASQ) with respect to the active and total installed processing capacity and the potential planning cycle demand estimate of 360 MMBF.

Comment: One comment stated that the: "Figure 3.13-11 on page 3-261 (of the Draft EIS) incorrectly depicts the volume that must be harvested to supply a veneer plant and an MDF plant. The 80 to 100 MMBF of utility logs and chips required by an MDF facility cannot realistically be produced from 250 MMBF of timber harvest."

Response: This comment is not clear. There is no Figure 3.13-11 on this page. It is possible that the comment author actually meant to refer to Table 3.13-11, which is on this page, but the comment does not appear to pertain to this table, which identifies the sawlog and utility volume identified for each alternative and does not identify the volume needed to supply a veneer plant or any other specific facility. The ability of each alternative to supply the minimum volumes required by various processing facilities is evaluated in the timber demand analysis in the *Economic and Social Environment* section of the EIS.

Comment: Many comments disagreed with the estimates of demand presented in the Draft EIS. Some requested that the Final EIS be clear that not everyone agrees with these estimates of demand.

Response: Projected timber demand is discussed in detail in the *Economic and Social Environment* section of the Final EIS. This section presents a range of demand estimates and projections, and discusses uncertainty about future demand, other studies, and differences of opinion.

Comment: One comment pointed out that the likelihood of a third party developing an MDF or veneer plant in Southeast Alaska was very low, even under Alternative 7. The comment author cited the recent closure by Weyerhaeuser of two of their veneer plants in Oregon. Weyerhaeuser reportedly stated that these closures were the result of reduced demand for plywood panels due to the decline in the housing market and the increased availability of competing products. The comment author pointed out that Weyerhaeuser supplied these mills from tree farms adjacent to highways and the facilities themselves were located less than two hours from a major Pacific port.

Response: The derived demand scenarios developed by Brackley et al. (2006a) presented MDF plants as an example of how derived demand for low-grade and utility wood might be stimulated. Other possibilities include development of biofuels markets, bioenergy applications, or shipment to markets and processors elsewhere. Chip prices are volatile and depend on many factors; if chip supplies go down regionally and demand increases, prices will increase to the point that shipments of low-grade material over longer distances will become a viable option. In the case of biofuels or bioenergy, as the prices of substitutes (e.g. oil and gas) increase, the probability of using wood products in these applications will increase. The scenarios presented in Brackley et al. (2006a) are designed to encompass a variety of future possibilities.

Comment: A number of comments stated that it is not the Forest Service's responsibility to develop a wood products industry in Southeast Alaska if that industry cannot be operated in an economically and ecologically sustainable manner. Others felt that the current industry was sustainable.

Response: The Forest Service is required to seek to meet market demand under the terms of TTRA. The existing and proposed Forest Plans are designed to ensure that timber harvest on the forest is conducted in a manner that is ecologically sustainable. The EIS evaluates potential demand using a number of possible future scenarios. The timber industry will not develop in the region if individual facilities are not economically sustainable (i.e., able to operate at a profit).

Comment: One comment stated that given that the Forest Plan is revised every 5 years it is not necessary to project timber demand far into the future and current demand levels should be used as a guideline.

Response: The Forest Plan undergoes a periodic review process every 5 years. The results of the most recent 5-year review are discussed on the Tongass National Forest's 5-year review web site (http://www.tongass-5yearreview.net/). The review process is not, however, the same as revising or preparing a new plan, this occurs every 10 to 15 years.

The Tongass estimates timber demand on an annual basis, but is also required under TTRA to seek to meet demand for each planning cycle. In order to seek to meet this demand, it is necessary to develop projections of demand over the planning cycle and into the future. It is, however, also important to note, as stated in the Draft and Final EIS documents, that the Forest Plan itself does not authorize any timber harvest. Rather, harvest is authorized by site-specific timber sale projects, which implement the plan. In other words, the plan does not directly meet demand for timber; rather it sets the conditions under which the Forest Service can seek to meet market demand through the cumulative sales of the annual timber sale program over the planning cycle.

Comment: One comment asked whether TTRA requires the Forest to meet global timber demand or only local demand.

Response: The TTRA does not make a distinction between local and global demand. The Tongass seeks to meet annual demand with the timber offer calculation outlined by Morse (2000). The calculation of planning cycle demand by PNW Research Station scientists is derived demand in end markets for Tongass wood products, wherever those end markets may be.

Regional Economy

General

Comment: One comment stated that the McDowell Group's 2007 report to the Southeast Conference shows that population in Southeast Alaska has decreased since 2000, while the total population in Alaska has increased by 6.9 percent over the same period. The comment authors urged that the Forest Service to consider and use this information in the Final EIS.

Response: This information is presented in both the Draft and Final EIS documents. See Table 3.22-33 in the Draft EIS. (Note that according to the U.S. Census Bureau, the population of Alaska grew by 5.9 percent between 2000 and 2005, not 6.9 percent as stated in the comment [Table 3.22-33; U.S. Census Bureau 2007]). Population data for 2006 are now available and have been added to the Final EIS. These data indicate that the population of Southeast Alaska declined from 70,822 in 2005 to 70,053 in 2006 (Alaska DOL 2007a).

Comment: One comment noted that population has increased by 31 percent in Southeast Alaska since closure of the pulp mills and total personal income increased by 14 percent. The comment author noted that if the timber industry really were the "be all and end all" of the Southeast Alaska economy, these numbers would be going down, not up.

Response: Data for key economic indicators for 1995 and 2004 are presented in Table 3.22-1 in the Draft and Final EIS documents. These data do not support the trends identified in the above comment. When adjusted for inflation, total personal income decreased by 4 percent over this period and per capita income decreased by 1 percent. Total population decreased by 4 percent over this period and total employment was approximately the same in 2004, as in 1995. These data provide a useful overview of the Southeast Alaskan economy, but it is important to understand that the costs and benefits of the current transition in the regional economy are not evenly distributed. This is discussed further in the *Subregional Overview and Communities* section of the EIS.

Comment: One comment cautioned the use of regional statistics to evaluate the economy of Southeast Alaska and pointed out that Juneau accounts for 40 percent of the population and more than half of the region's economy, and may mask significant trends in other parts of the local economy.

Response: This concern is specifically addressed in the Draft and Final EIS documents. The section of the EIS that characterizes the Regional and National Economy presents regional data, as noted in the comment, but cautions that the trends exhibited by these data are not evenly distributed throughout the region and refers the reader to the *Subregional Overview and Communities* section of the document. The *Subregional Overview and Communities* section of the EIS addresses this concern directly and provides and analyses data at the Borough and Census Area level. This is noted on the second page of the *Economic and Social Environment* section of the EIS.

Comment: One comment stated that the 1995 total personal and per capita income figures for Southeast Alaska presented in 2005 dollars in Table 3.22-1 appear to be incorrect.

Response: The 1995 income figures presented in Table 3.22-1 were developed using data from the U.S. Bureau of Economic Analysis (2006a). These data are compiled by Borough and Census Area. The estimates presented in Table 3.22-1 were developed by combining the Bureau of Economic Analysis data for the Boroughs/Census Areas that comprise Southeast Alaska. The resulting estimates were then adjusted for inflation using the Consumer Price Index (All Urban Consumers). A review of these calculations did not identify any errors. Table 3.22-1 has been updated in the Final EIS.

Comment: One comment stated that the data presented in Table 3.22-3, which estimate natural resource-based employment for 1995 and 2004, "significantly understate the magnitude of the decline experienced by the timber products industry following the passage of the Tongass Timber Reform Act in 1990."

Response: Table 3.22-3 is part of the section of the EIS that provides a general overview of natural resource-based industry in Southeast Alaska and is not intended to illustrate the full extent of the reduction in wood products employment that has occurred since employment peaked at 3,543 jobs in 1990. (Note that this table has been updated and revised in the Final EIS). The general overview is followed by sections that discuss specific natural resource-based industries in detail. The section that discusses the wood products industry presents employment data from 1986 to 2005.

Comment: One comment stated that the EIS should explain that the data presented in Table 3.22-2 provide a poor representation of the contribution made by natural resource-based industries to the economy of Southeast Alaska, especially the commercial fishing and recreation and tourism sectors. Another comment noted that this table "inexplicably" lumps together "forestry, fishing, related activities, and other" into one category and fails to distinguish between these important sectors.

Response: The shortcomings of the data presented in Table 3.22-2 are discussed with respect to Recreation and Tourism in the paragraphs immediately following Table 3.22-2. (Note this table has been updated in the Final EIS). The section of the EIS that follows Table 3.22-2 presents estimates of natural resource-based employment by sector and includes estimates of commercial fishing and recreation and tourism-related employment developed from other sources. More detailed employment estimates are provided in the following sections that address each natural resource-based industry in turn.

The data presented in Table 3.22-2 are from datasets compiled by the U.S. Bureau of Economic Analysis. These data are compiled and made available in accordance with the North American Industry Classification System (NAICS), which groups establishments and employees into the categories shown in Table 3.22-2.

Comment: Several comments expressed the concern that the economic analysis in the Draft EIS failed to adequately consider the impacts of logging on other sectors of the economy, and failed to adequately quantify other sectors. One comment noted that the Draft EIS "alternatives fail to consider the economic realities of standing forest and what it represents monetarily via tourism and other recreational and commercial uses beyond timber." One comment recommended that logging be phased out as jobs increase in recreation, tourism, and other sectors. Another comment noted that timber harvest is a single use of the forest that reduces other uses of harvested areas for many decades.

Response: The economic and social analysis presented in the EIS assesses the potential economic impacts of the proposed alternatives on recreation and tourism in terms of the effects that projected timber harvest and associated road building would have on available recreation opportunities on the Forest. The current and proposed Forest Plans include standards and guidelines specifically designed to protect Forest values and resources and the economic activities and values associated with them.

The affected environment portion of the *Economic and Social Environment* section discusses natural resource-based economic sectors of the economy at some length, including wood products, recreation and tourism, commercial fishing, mining, and the economic value of natural amenities and quality of life. The environmental consequences addresses the potential impacts to these resources, as well as other non-use values, including passive use values and ecosystem services.

Comment: A number of comments expressed concern that timber harvest in areas surrounding local communities or areas that are popular for recreation and other uses would have detrimental effects on these areas and the economic activities that depend upon them. The same concern was expressed with respect to fish and the recreational angling and commercial fishing industries that depend on healthy populations of fish.

Others expressed the same general concern, noting that the Tongass National Forest is worth more intact than as harvested timber. Along these lines, many comments stated that the Forest should be managed to support sustainable levels of recreation and tourism, commercial fishing, and subsistence, with timber harvest limited to small sales for local, value-added processing.

Response: Concerns raised with respect to impacts to specific places are addressed in Section C of this appendix. In general, it may be noted that this EIS provides a programmatic forest-wide analysis appropriate for a strategic Forest Plan Amendment. Site-specific projects or activities are best examined locally during the decision making process as appropriate for that action. Specific concerns raised with respect to the potential impacts of the proposed alternatives on the commercial and recreational fishing industries are addressed in the following Commercial Fishing subsection.

The management alternatives presented in the EIS are all designed to support sustainable levels of recreation and tourism, commercial fishing, and subsistence. The areas potentially available for timber harvest would, however, vary by alternative, with projected harvest volumes ranging from approximately 49 MMBF per year under Alternative 1 to 421 MMBF per year under Alternative 7.

Comment: One comment requested that the EIS disclose the opportunities for commercial timber, minerals, and other uses that are foregone in areas allocated to Wilderness, National Monument, OGRs, and other restrictive LUDs. They requested that these foregone opportunities be quantified in acres, volume, value, and improved habitat.
